Beryciforms are the most primitive fishes of the four groups under discussion, exhibiting primitive features: the presence of two supramaxillary bones in the upper jaw; an orbitosphenoid bone between the eyes; a tail fin containing 19 principal rays, which insert on six hypural bones supported, in turn, by two vertebrae. Occasionally, they have teeth on the maxillary bone (in the modern holocentrid *Myripristis* and a few Cretaceous fossils). There are many ways in which beryciforms approach the perciforms, the typical "spiny-rayed" fishes. Such resemblances are seen in a number of features: the structure of the mouth, with a normal acanthopterygian pattern of jaw muscles and ligaments; the spiny head bones and ctenoid scales (with a serrated edge); a projection called a subocular shelf on the bones below the eye; stout spines in front of the dorsal, anal, and pelvic fins; bony contact between the pelvic and pectoral girdles; and the short, deep trunk, with about 25 vertebrae. The more generalized beryciforms (holocentrids, trachichthyids, and berycids) exhibit all of these features, but in several lineages degeneration has occurred, associated with life in the deep. In such deep-sea beryciforms as the big-scale fishes (Melamphaeidae), fin spines tend to be absent, the pelvic fins have moved back to the abdomen, and the head bones and scales have become thin and flimsy. Also, in some species primitive structures such as the orbitosphenoid and supramaxillary bones are lacking, and fusions within the tail skeleton have resulted in a condition resembling that of perciforms. The swim bladder is reduced or lost in some.

Structurc of zeiforms

Anatomically, the zeiforms resemble perciforms more closely. Almost the only feature that distinguishes zeiforms from perciforms is the presence, in the former, of two or three more rays in the pelvic fins, and in some zeiforms even this distinction fails to hold. Nevertheless, these extra pelvic rays and a few other features, notably the structure of the otoliths ("ear stones," used in maintaining balance), indicate that the zeiforms are beryciform relatives that have independently attained the perciform evolutionary level. Typically, the zeiform has a highly protrusible mouth, a separate spinous dorsal fin, ctenoid scales, and a short, deep trunk; the most primitive members of the order have 24 or less vertebrae.

The most primitive lampridiforms are also deep-bodied fishes, with spines in front of the dorsal and anal fins, the

Structure of lampridiforms

pelvic fins directly below the pectorals, an orbitosphenoid bone in the skull, and a tail fin with 19 principal rays, in which they resemble beryciforms. Lampridiforms differ from beryciforms, however, in never having a subocular shelf or pelvic spine, in having more numerous vertebrae, and in having the upper tail fin supports fused with an independent vertebral centrum, a condition resembling that found in the cods and their relatives (Paracanthopterygii). Most lampridiforms have highly protrusile jaws in which depression of the lower jaw dislocates the maxilla of the upper, so that it moves forward bodily, carrying the premaxilla with it. This is a different method from that adopted by other acanthopterygians, hence the name allotriognaths ("strange-jaws") originally applied to the group. A parallel can be drawn between the beryciforms and lampridiforms in certain modifications exhibited by the deep-sea forms, compared with their surface-living relatives. These include the loss of fin spines, reduction in ossification, and reduction of the swim bladder. The most striking features of the more highly evolved lampridiforms, however, are peculiar to the group: great elongation of the trunk, accomplished by increase in vertebral number and elongation of the vertebrae themselves, and reduction of the tail to a small, asymmetrical or filamentous appendage.

Structure of atheriniforms

The atheriniforms are an extremely varied group. There are many structural resemblances to more advanced acanthopterygians, but these are in mosaic distribution, indicating that most have been independently acquired. The jaws of many atheriniforms are protrusile, but the structural modifications by which this is achieved are quite different from those of typical acanthopterygians. The simple, shelflike head of the maxillary bone is attached to the palate only by ligaments, not by a mobile joint. The premaxilla is longer than the maxilla and also has a simple head. Protrusion of the jaws is accomplished by twisting the maxilla and displacing its head forward; the complex system of joints and ligaments characteristic of other acanthopterygians is not developed. The palate is usually toothless, and the series of infraorbital bones incomplete, only the first (lachrymal) and last (dermosphenotic) bones being present. The skull bones are not spiny, but the scales are often ctenoid. The pelvic girdle may have a ligamentous connection with the shoulder girdle but often lies further back, and the girdles never acquire the direct contact that characterizes higher acanthopterygians. The pelvic fin has six or fewer rays, but there is no pelvic spine. The atheriniform tail skeleton is of an advanced type, usually with two large plates emanating from a single supporting centrum, as in some advanced perciforms. The caudal fin contains 17 or less principal rays. There are a few spines in front of the dorsal and anal fins in many atheriniforms, and the members of the Atherinidae and Phallostethidae have a small, separate spinous dorsal fin, but atheriniform spines appear to have evolved independently from those of true acanthopterygians.

An extreme example of adaptation to life near the air-water interface, the habitat of most atheriniforms, is the eye of *Anableps,* the four-eyed fish, so named because each eye is a double structure. The eye is set high on the head and the upper part projects above the water. The cornea is divided by a horizontal band of pigment, separating an upper, strongly convex part from a lower, flatter division. The iris has a pair of projections partially dividing the pupil into two, and the upper is effective for aerial vision, the lower for underwater vision.

Much work has been done on the genetics of atheriniforms, perhaps the most surprising result being the hatching of hybrids between *Fundulus* (Cyprinodontidae) and *Menidia* (Atherinidae), fishes placed in separate suborders. A physiological peculiarity of some marine atheriniforms, garfishes and needlefishes, is a bright green coloration of the bones and even the flesh, due to retention of a bile pigment, biliverdin.

EVOLUTION, PALEONTOLOGY, AND CLASSIFICATION

Paleontology. The four orders Beryciformes, Zeiformes, Lampridiformes, and Atheriniformes are primitive groups within the superorder Acanthopterygii. The Beryciformes and Zeiformes apparently form a related group, originating in the Cretaceous, its closest relatives being the Perciformes. The Lampridiformes also originated in the Cretaceous and are of uncertain relationships, being to some extent intermediate between the Acanthopterygii and Paracanthopterygii. The Atheriniformes represent a radiation from near the base of the acanthopterygian stock, but their exact relationships within this group are not known. The present distribution of atheriniforms indicates that the group arose in fresh or brackish waters of the tropical Indo-Pacific region, but little is known of their early fossil history.

Annotated classification.

ORDER BERYCIFORMES

Spiny-rayed fishes with a pelvic spine, an orbitosphenoid, and 19 principal rays in the tail. Of the two main lineages the first contains the Holocentridae, coastal fishes of warm seas. The second is a series of oceanic families centring around the Trachichthyidae. Both groups have fossil records back to the Cretaceous, the 2 lines converging in the Middle Cretaceous.

Family Holocentridae (soldierfishes and squirrelfishes)
Circumtropical, with partly separate spinous dorsal fin. Several extinct genera, Middle Cretaceous onward.

Family Monocentridae (pinecone fishes)
Armoured, very spiny. Teeth on endopterygoid bone. Two genera; Indo-Pacific.

Family Trachichthyidae
Midwater (mesopelagic) or deepwater pelagic fishes, worldwide. Skull bones cavernous, with large mucus cavities. Several extinct genera, Middle Cretaceous onward.

Family Berycidae (alfonsinos)
Upper and midwaters in open ocean; worldwide. Pelvic girdle enlarged and tightly joined with the pectoral.

Family Anoplogasteridae
Deep-sea, adults with large fangs; 1 genus.

Family Diretmidae
Very deep bodied, compressed fishes; 1 genus.

Family Anomalopidae (lantern-eyed fishes)
With subocular luminous organ, found near the surface at night; 2 Indo-Pacific genera, 1 Atlantic.

Family Stephanoberycidae (prickle fishes)
Scales and head spiny, fin spines reduced; bathypelagic, worldwide; 3 genera.

Family Melamphaeidae (big-scale fishes)
Abundant deepwater open ocean fishes, worldwide; softbodied and black. Fossils in the Miocene.

Family Gibberichthyidae
Like Melamphaeidae but with stronger fin spines. Atlantic, 1 or 2 genera.

Family Rondeletiidae (whale fishes)
Head large, no scales, fin spines, or swim bladder; bathypelagic, 1 genus.

Family Cetomimidae (whale fishes)
Mouth huge, spineless fins, bathypelagic, worldwide.

Family Barbourisiidae (whale fishes)
No fin spines, scales reduced to minute spines, red, bathypelagic, 1 genus.

ORDER ZEIFORMES

Like Perciformes but with up to 9 pelvic rays and only 12–13 principal caudal rays.

Family Caproidae (boar fishes)
Most primitive family, 21–23 vertebrae, fossils in the Oligocene; 2 genera, worldwide.

Family Zeidae (John Dories)
Deep bodied and laterally flattened. Mouth large; scales reduced; more than 30 vertebrae. Several genera, worldwide; fossils in the Eocene.

Family Grammicolepididae
Mouth very small, scales drawn out into oblique bands. Two genera, mesopelagic.

Family Oreosomatidae
Larva covered with large tubercles. Four genera, benthic (bottom dwelling); worldwide.

Families Zeniontidae and Macrurocyttidae
Two small families, the first with two genera, the second with one, too poorly known to be characterized.

ORDER LAMPRIDIFORMES

Similar to Beryciformes, but with no pelvic spine; upper hypural bones fused with their supporting centrum.

Suborder Lampridoidei

Deep-bodied forms.

Family Veliferidae

One living genus (*Velifer*) with saillike fins, 33 vertebrae. Fossils from Paleocene and Eocene, several extinct genera.

†*Families Aipichthyidae and Pharmacichthyidae*

Extinct families, each containing a single Upper Cretaceous genus; appear to be primitive lampridiforms, resembling *Velifer* in deep trunk, but with fewer vertebrae and more primitive tail skeletons.

Family Lampridae (opahs)

One genus (*Lampris*); 15–17 pelvic rays, 46 vertebrae. Fossils from Miocene. Length to 2 m (6½ ft), weight to 140 kg (over 300 lb); surface waters (epipelagic) of warm seas; widespread.

Suborder Trachipteroidei

Ribbonlike, about 100 vertebrae.

Family Trachipteridae (dealfishes)

Pelvic fins with 5–9 rays, no anal fin, jaws toothed. Length to 1.2 m (4 ft); epipelagic. Worldwide in warm seas.

Family Lophotidae (unicorn fishes)

Scales lacking; pelvic fins small or absent, anal fin short. Fossils from Oligocene. Worldwide in warm seas.

Family Regalecidae (oarfishes)

Anal fin lacking; 1 pelvic ray elongated; jaws toothless; length to 9 m (30 ft); weight to 300 kg (660 lb). Mesopelagic, tropical.

Suborder Stylephoroidei

Family Stylephoridae

Deep-sea forms with enlarged telescopic eyes, about 50 vertebrae, 2 filamentous caudal rays. Known from only a few specimens.

Suborder Ateleopoidei

Family Ateleopidae

Specialized, deep-sea, bottom-living fishes, Indo-Pacific and Atlantic, usually placed among the primitive teleosts, but probably lampridiform.

Suborder Mirapinnoidei

Families Mirapinnidae and Eutaeniophoridae

Three species of little-known mesopelagic fishes, usually placed as a distinct order of lower teleosts (Mirapinniformes), but probably larval lampridiforms.

Suborder Megalomycteroidei

Family Megalomycteridae

Four rare, little-known, deep-sea genera, probably larval lampridiforms.

ORDER ATHERINIFORMES

Premaxilla greatly expanded between maxilla and mandible, without crossed ligaments controlling the upper jaw, infraorbital bone series incomplete.

Suborder Exocoetoidei

Lateral line complete and low on the flank in marine forms, the lower pharyngeal bones are fused, no parietals, 9–15 branchiostegals. Found worldwide, but especially abundant in the Indo-Pacific.

Family Exocoetidae (halfbeaks and flying fishes)

Lower jaw often extended; snout not modified. Surface marine waters and freshwaters, worldwide; length to 45 cm (18 in.). Fossil half-beaks in the middle Eocene.

Family Belonidae (garfishes and needlefishes)

Snout bones sutured together, both jaws elongated into a strongly toothed beak. Mostly temperate and tropical marine; a few freshwater; length to 120 cm (almost 48 in.). Fossils in the Oligocene.

Family Scomberesocidae (sauries, skippers)

Snout and jaws as in Belonidae but feebly toothed; small finlets behind dorsal and anal fins. Inshore temperate and tropical marine waters; length to 35 cm (almost 14 in.). Fossils in the Miocene.

Suborder Cyprinodontoidei

Lateral line represented by pits on the flank, 4–7 branchiostegal bones. Families mostly distinguished by reproductive specializations.

Family Oryziatidae (medakas)

Most primitive cyprinodonts; a single genus in freshwaters and brackish waters in Indonesia.

Family Adrianichthyidae

Mouth and snout enlarged and shovellike. Two genera in lakes in Celebes; length 7–20 cm (2¾ to almost 8 in.). Fossils in Late Tertiary in Celebes.

Family Horaichthyidae

Small fishes with anal fin modified, in males, for clasping female in mating. One genus, freshwater, India.

Family Cyprinodontidae (killifishes or egg-laying topminnows)

Circumtropical and temperate marine and freshwater, many genera. Many popular aquarium fishes; length to 15 cm (6 in.). Fossils in the Oligocene.

Family Goodeidae (Mexican topminnows)

Live-bearing, but male lacks elaborate intromittent organ found in poeciliids. About 10 genera, in rivers draining the Mexican Plateau; length to about 10 cm (4 in.).

Family Jenynsiidae

Small fishes with asymmetrical genital organs; 1 genus; rivers of South America.

Family Anablepidae (four-eyed fishes)

Characterized by specialized eye structure (see above *Form and function*); 1 genus, 2 species; surface waters in rivers and estuaries of South America.

Family Poeciliidae (live bearers or viviparous topminnows)

Native to tropical and subtropical America but introduced elsewhere for mosquito control. Freshwaters and coastal marine waters. Length 1.5 to about 15 cm (over ½ to 6 in.). Family includes mollies (*Mollienesia*), guppies (*Lebistes*), swordtails (*Xiphophorus*), and many other popular aquarium fishes, as well as the mosquito fishes (*Gambusia*).

Suborder Atherinoidei

Lateral line variable; 5–7 branchiostegal bones; separate spinous dorsal fin.

Family Melanotaeniidae

Many species; freshwater bodies of New Guinea and Australia. Compressed, deep-bodied; pointed snout; 5–20 cm (2 to 8 in.).

Family Atherinidae (silversides)

Lateral line absent; pelvic fins midway along belly; length 7–70 cm (2¾ to 27½ in.). Coastal and freshwater, worldwide in warmer regions. Many genera. Fossils from middle Eocene.

Family Isonidae

Pectoral fins unusually high on body. Small marine fishes; Indian and Pacific Oceans. Two genera.

Families Phallostethidae and Neostethidae

Males with priapium, an organ derived from pectoral and pelvic girdles, functioning to clasp the female. Tiny fishes (3–5 cm [1 to 2 in.] long); confined to freshwaters and brackish waters in Thailand, Indonesia, and the Philippines.

Critical appraisal. The whale fishes (cetomimids, rondeletiids, barbourisiids) are often placed in a separate order Cetomimiformes, thought to be more primitive than Beryciformes, but their "primitive" features appear to be due only to degeneration. The stephanoberycids, melamphaeids, and gibberichthyids are usually placed in a suborder Stephanoberycoidei, all other beryciforms being placed in the Berycoidei, but the major phyletic cleft in Beryciformes seems to be between the holocentrids and the remainder, which form a related group. (C.P.)

Sticklebacks, tube snout, sea horses, and allies (Gasterosteiformes)

Gasterosteiformes is an order of fishes characterized generally by soft fin rays, pelvic fins located on the abdomen, an air bladder without a duct to the gut, and a primitive kidney. Gill structures are somewhat degenerate. Most species have bony rings around the body or ganoid (*i.e.*, thick, bony, enamelled, and diamond-shaped) plates rather than scales. Families within the order are Gasterosteidae (sticklebacks), Aulorhynchidae (tube snout), Indostomidae (indostomid), Aulostomidae (trumpet fishes), Fistulariidae (cornetfishes), Centriscidae (shrimpfishes), Macrorhamphosidae (snipefishes), Solenostomidae (ghost pipefishes), and Syngnathidae (pipefishes and sea horses).

Gasterosteiform fishes occur in both salt water and freshwater and are widely distributed. The smallest species are about three centimetres (about 1¼ inches) long, the largest about 200 centimetres (about 80 inches). They

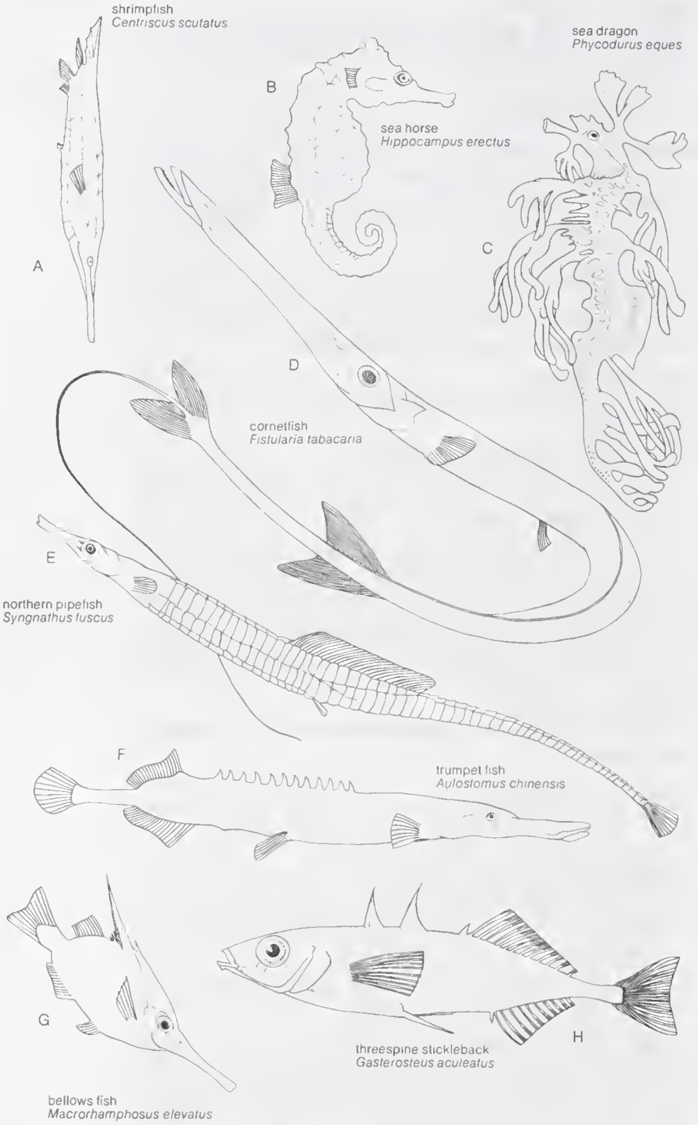

Figure 31: Representative gasterosteiform fishes.

Drawing by J Helmer based on (G, F) G Whitley and J. Allan, *The Sea-Horse and Its Relatives*, (D, E, H) A H Leim and W B Scott, *Fishes of the Atlantic Coast of Canada* (1966), Fisheries Research Board of Canada, reproduced by permission of Information Canada

are of limited economic importance, but many forms are popular aquarium fishes. Two families, Indostomidae and Aulorhynchidae, are represented by only one species each.

NATURAL HISTORY

Reproduction and life cycle. Except for sticklebacks, pipefishes, and sea horses, little is known of the life cycles of Gasterosteiformes. The male stickleback builds nests of plant materials cemented together with mucus secretions. The usually drab body hues of the male change, reflecting red, which is sexually attractive to the female. Male pipefishes and sea horses brood the eggs, deposited by the female within the male's brooding pouch. The brooding organ of the male sea dragon is a specialized area of soft skin beneath the tail. In some ghost pipefishes, eggs are fastened to the female on filaments of skin in pouches formed by specialized fins on the ventral, or lower, side. The dwarf sea horse, *Hippocampus zosterae,* breeds nine months of the year; eggs hatch after 10 days into miniatures of the adult. They mature in two or three months and live less than a year. Tube snouts deposit eggs in cavities of ascidia (primitive colonial chordates) or in masses of algae bound with threads secreted in a manner similar to that of sticklebacks. Egg clusters, often multiple, are cared for by the male. Snipefish eggs are enveloped in a mucilaginous substance from which the larvae are freed as development proceeds. Cornetfishes lay free pelagic (*i.e.,* drifting) eggs; thus, they do not receive parental care. The reproductive habits of shrimpfishes and trumpet fishes are unknown.

Brooding organ of the male

Ecology and behaviour. For defense, most gasterosteiforms assume a vertical position among grasses, gorgonians (*i.e.,* sea fans, a type of coral), and sea urchins. Such a posture serves to camouflage them; it also tends to present body spines or shields to predators normally oriented to the horizontal plane.

In most families, locomotion is by means of the caudal, or tail, fin. Snipefishes swim forward or backward with equal ease on the vertical plane and do not seek shelter among marine growths. The caudal fin is absent in sea horses. The coiled tail of the sea horse is used for gripping seaweed and other plants or objects. Propulsion is by means of the dorsal fin (*i.e.,* the large fin arising from the midline of the back). Tiny pectoral fins are used for steering. Vertical movement is by swimming. All fishes with an air bladder use it to some degree for vertical motion. With little effort the sea horse rises or settles to another depth by changing the air volume within the bladder.

With the exception of the snipefishes, most gasterosteiforms live among a wide variety of aquatic growths where they find food and safety and reproduce. Certain pipefishes and sticklebacks, in particular, are able to tolerate a wide range of salinity.

FORM AND FUNCTION

Sticklebacks are the most varied in form. The number of spines and bony plates is greatest in individuals living in the ocean. Each heavily armoured marine species is represented by half-mailed or naked (plateless) varieties in brackish or fresh waters. They are small scaleless fishes that grow to about 15 centimetres (six inches) in length. The short jaws are well armed with sharp teeth. The body is more nearly fusiform (*i.e.,* tapered at both ends) than are those of other members of the order. Body plates may be absent or may vary in number. The soft dorsal fin is preceded by from two to 11 free spines, each connected to the dorsal surface by its own triangular membrane. Pelvic fins are thoracic (*i.e.,* near the midsection) in position, each with a well-developed spine and one or two soft rays. The anal fin is preceded by a spine. The caudal fin is truncate (*i.e.,* abbreviated).

Sticklebacks

The body of the tube snout is elongated, slender, and cylindrical. It is tipped by a prolonged snout, the small, toothed mouth of which has a hinged upper jaw. The scaleless body is armoured with series of embedded bony plates. The first dorsal fin is represented by about 25 free spines; the rayed dorsal fin is far back on the body above the anal fin. Pectoral fins are broad and the caudal fin furcate (forked).

In the indostomids the elongated body is covered with bony rings as in pipefishes and sea horses. The small mouth is at the tip of the snout. The teeth are minute, the gills rather lobe shaped, and the eyes large. The anterior (*i.e.,* forward) dorsal fin consists of five isolated spines. Ventral fins (*i.e.,* paired fins arising from the sides of the belly) bear no spine, have four rays each, and are located not far behind the pectorals. The anal fin is below the soft dorsal fin, and the rounded caudal fin has a short peduncle, or stem.

Trumpet fishes, which seldom grow to more than 30 centimetres (one foot) in length, have an elongated, compressed, scaled body; the snout is prolonged into a rigid tubelike beak. The short, weak jaws have minute teeth. There are numerous dorsal spines. The ventral fins are abdominal; the caudal fin is truncate.

Cornetfishes, which grow to more than 180 centimetres (six feet) in length, are similar in structure to trumpet fishes; however, there are no scales. Instead, bony plates are embedded in the skin. Dorsal spines are absent, and the ventral fins are located in the abdominal region; each has a spine and four rays. Four anterior vertebrae are elongated. The backbone extends through the forked caudal fin as a long central filament.

Shrimpfishes, also known as razor fishes, are small, with toothless jaws at the end of a long snout. Scales are absent; the back is covered by transparent plates, forming the cuirass. Anteriorly the cuirass is affixed to the ribs;

posteriorly it extends beyond the displaced dorsal, caudal, and anal fins. The body is compressed to a sharp edge ventrally; hence the name razor fish.

In snipefishes the tubular snout has short jaws. The body form is variable, but all snipefishes tend to be short and deep and partly covered with the bony-plated cuirass, which is strengthened by its union with parts of the vertebrae. Areas lacking plates sometimes have scales. In addition to having several shorter spines, the dorsal fin has a very long, strong, serrated spine reaching nearly to the tip of the caudal fin. Each ventral fin has one spine and five rays. A long snout, and two posterior "handles" of spine and tail lends an appearance that is the basis for another common name, bellows fish.

Ghost pipefishes have a tubular snout tipped with a small mouth; the short body has spinous dorsal and ventral fins. Gills are reduced to lobe-shaped tufts attached to rudimentary gill arches. Bony plates unite to form rings. This supporting external framework has reduced the need for well-developed musculature. Ventral fins and a pointed caudal fin are large in proportion to the body size.

Pipefishes

Pipefishes are long and slender. The axis of the head is in line with that of the body, and the long snout is tipped with a small mouth. Bony rings replace scales. The dorsal and pectoral fins are spineless, and ventral fins are absent. Generally, the caudal fin is rounded and reduced, but it is effective in moving the fish rapidly through the water. The slender posterior body portion, though not truly prehensile (*i.e.*, capable of coiling and grasping), can be somewhat used in that manner. Sea horses are similar to pipefishes but differ in several important respects. The head is at an angle to the body proper. This, in addition to the shape of the head, creates a somewhat horselike appearance. The tail is prehensile and lacks a caudal fin.

EVOLUTION AND CLASSIFICATION

Paleontology. Gasterosteiformes appears to represent an early but highly specialized branch of the Acanthopterygii. Its evolution has been traced through limited paleontological data. Fossil sticklebacks occur in Miocene (7,000,000 to 26,000,000 years ago) strata and are moderately abundant in Tertiary (2,500,000 to 65,000,000 years ago) strata. Most of the order occurs in fossil remains in Eocene (38,000,000 to 54,000,000 years ago) and Oligocene (26,000,000 to 38,000,000 years ago) strata in the area of Monte Bolca near Verona, Italy. Deposits there (and in Sumatra) include an extinct family, Protosyngnathidae, related to the tube snouts. Trumpet-fish species, a closely related extinct scaleless family, Urosphenidae, and a small species of cornetfish have also been found there. Shrimpfishes, too, are within these strata, as well as in Oligocene deposits in various parts of Europe. Snipefishes are represented by an extinct genus, as are ghost pipefishes. Pipefishes occur in Miocene deposits in Sicily. Tertiary rocks contain *Syngnathus* and *Calamostoma*, pipefish forms that have a close relationship to true sea horses. Fossil sea horses are unknown.

Distinguishing taxonomic features. The Gasterosteiformes are classified mainly on the basis of general body form, the structure and distribution of scales or body plates, fin form and position, and the structure of the skeleton and its individual parts.

Annotated classification. The classification here is essentially that of P.H. Greenwood *et al.* (Bulletin of the American Museum of Natural History, no. 131, 1966).

ORDER GASTEROSTEIFORMES

Eocene to Recent. Frequently with strong spines in dorsal and pelvic fins, spines absent in some; snout often elongated; body often with dermal plates; 9 families, marine and freshwater, widely distributed. Length about 3–200 cm.

Suborder Gasterosteoidei

Family Gasterosteidae (sticklebacks)

Jaws short, armed with sharp teeth; body quite fusiform (tapered at both ends); body plates may be absent or may vary in number; body length to about 15 cm (6 in.); 11 species, fresh, brackish, and marine waters of Northern Hemisphere.

Family Aulorhynchidae (tube snout)

Body elongated, slender, and cylindrical; snout long, upper jaw hinged. One species, occurs in northeastern Pacific Ocean.

Family Indostomidae (indostomid)

Body elongated, covered with bony rings; teeth minute, gills lobe-shaped, eyes large. One species, *Indostomus paradoxus*, found in Lake Indawgyi in northern Burma.

Suborder Aulostomoidei

Family Aulostomidae (trumpet fishes)

Body elongated and compressed sideways; jaws short and weak, teeth minute; dorsal spines numerous; length to about 30 cm (12 in.); about 4 species, tropical seas.

Family Fistulariidae (cornetfishes)

Similar in appearance to Aulostomidae; no scales, bony plates imbedded in skin; dorsal spines absent; backbone extends through caudal fin as a central filament. Grow to more than 180 cm (71 in.); about 4 species, tropical seas.

Family Centriscidae (shrimpfishes)

Body small, jaws toothless, scales absent, back covered by transparent plates; 4 species, shallow waters of Indian and Pacific Oceans.

Suborder Syngnathoidei

Family Macrorhamphosidae (snipefishes)

Snout tubular, jaws short, body rather short and deep; in profile shaped like bellows; 11 species, temperate and tropical seas.

Family Solenostomidae (ghost pipefishes)

Snout tubular, mouth small; body short, with spiny dorsal and ventral fins; bony plates united to form body rings; about 5 species, tropical Indo-Pacific waters.

Family Syngnathidae (pipefishes and sea horses)

Pipefishes long and slender, snout tipped with small mouth; dorsal and pectoral fins spineless, ventral fins absent. Sea horses with head bent downward in horselike relation to body; tail prehensile; bony rings instead of scales; about 24 species of sea horses, widely distributed, marine; about 150 species of pipefishes widely distributed in shallow tropical seas.

Critical appraisal. The American Fisheries Society (Special Publication No. 6, 1970) arranges the Gasterosteiformes as in Greenwood *et. al.*, above, with the following exceptions: the taxonomic level of suborder is not used; family Gasterosteidae is expanded to include family Aulorhynchidae; family Centriscidae is expanded to include family Macrorhamphosidae.

Of the several families considered in this article, the Indostomidae are the least known. The species of this family appear to be intermediate between Gasterosteidae and Aulostomidae.

A tenth family, Pegasidae, is tentatively placed between Gasterosteidae and Syngnathidae. Some authorities list them separately as Pegasiformes. These small fishes are the so-called sea moths, found in Asiatic seas. The toothless mouth is not terminal but lies under the head and is overhung by a snout, or rostrum, often adorned with spines. The body is protected by knobby armoured plates, with the posterior portion rather elongated, square to rectangular in cross section and bearing a small dorsal fin. Spines along either side of this region may be absent or developed to varying degrees. Pectoral fins form expansive fans on either side. Ventral fins are reduced to a few fingerlike rays used for crawling on the bottom. The pegasids have no air bladder. Swimming ability for more than short distances is poor. Fossils of Pegasidae are unknown. (W.Z.)

Scorpion fishes, rockfishes, gurnards, and allies (Scorpaeniformes)

The scorpaeniform, or mail-cheeked fishes, are widespread throughout the oceans of the world. The group is believed to have originated in warm marine waters but has invaded temperate and even Arctic and Antarctic seas as well as freshwaters of the Northern Hemisphere. The mail-cheeked fishes are a highly successful biological group, occurring in the sea from the midlittoral (coastal) zone down to depths of at least 4,000 metres (about 13,000 feet). They inhabit some deep freshwater lakes but are more abundant in cold streams and rivers. The order is often divided into six suborders, only two of which have more than one family; these are the Scorpaenoidei (three families) and the Cottoidei (seven families). The best known groups are the scorpion fishes and rockfishes (family Scorpaenidae), gurnards or sea robins (Triglidae), flatheads

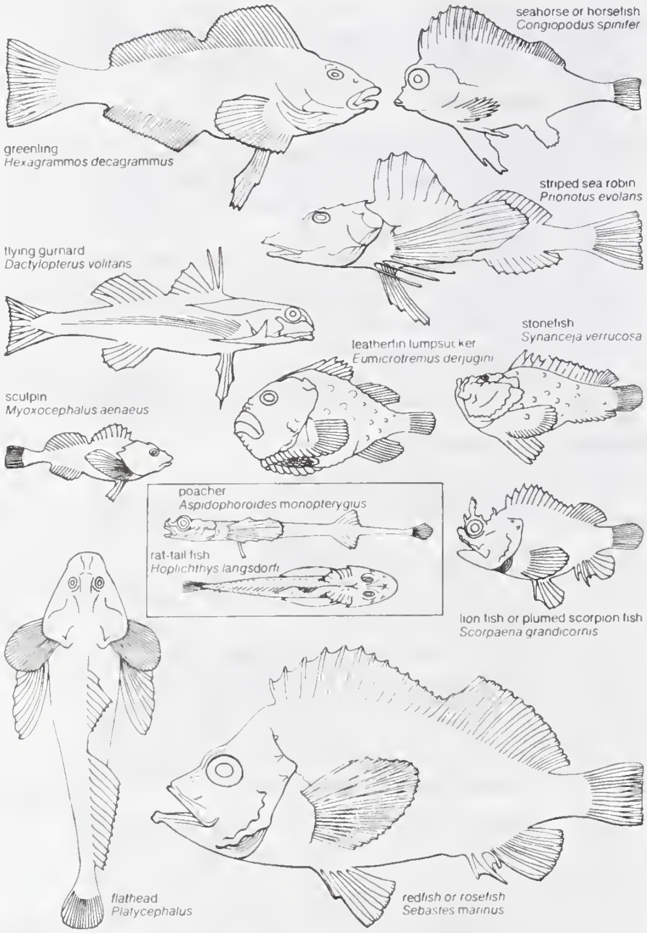

Figure 32: Body plans of representative Scorpaeniformes.

From (*Hexagrammos, Platycephalus*) Yaichiro Okada, *Fishes of Japan;* (*Congiopodus*) J L B Smith, *Sea Fishes of Southern Africa*, (*Prionotus, Dactylopterus, Aspidophoroides, Scorpaene, Sebastes*) D S Jordan, *A Guide to the Study of Fishes*, copyrighf 1905 by Holt, Rinehart and Winston, Inc., reprinted by permission of Holt, Rinehart and Winston, Inc , (*Eumicrotremus*) adapted from original drawing by D R Harriott in A H Leim and W B Scott, *Fishes of the Atlantic Coast of Caneda*, Fisheries Research Board of Canada Bulletin 155, (*Myoxocephalus*) reprinted by permission of G P Putnam's Sons from *Field Book of Marine Fishes of the Atlentic Coast* by Charles M Breder, Jr , copyrighf © 1929 by Charles M Breder, Jr , renewed 1957 by Charles M Breder, Jr

(Platycephalidae), and sculpins (Cottidae). The flying gurnards (Dactylopteridae), considered by some authorities to belong in this order but more often separated in the order Dactylopteriformes, are treated here for convenience.

GENERAL FEATURES

Many members are locally important commercial fish. Thus the redfishes of the genera *Sebastes* and *Sebastodes* of the North Atlantic and Pacific have considerable value to the fishing industries of Europe, Russia, and North America; the flatheads are exploited in a wide area of the Indo-Pacific region, and greenlings (Hexagrammidae) are of commercial importance in the northwestern Pacific. In general, the fishery value of the group as a whole has a greater potential than is shown by the present actual utilization by man.

Members of the order Scorpaeniformes are not large fishes. Some of the deepwater species, such as the redfishes, grow to a length of 90 centimetres (three feet), but the majority attain a maximum length of around 30 centimetres (one foot). Externally, scorpaeniforms vary greatly; most are like the Perciformes in general appearance—*i.e.,* they are typical, scaled, spiny-rayed fishes—but the lumpfishes (Cyclopteridae) among them are obese, often jellylike, and usually scaleless and lack sharp fin spines. Body armour is often well developed, however, and most scorpaeniforms are well equipped with spines.

NATURAL HISTORY

Ecology. The greatest diversity of scorpaeniform fishes, especially among members of the family Scorpaenidae, is found in warm tropical seas. The order is particularly well represented in the shallow waters of the continental shelf. In the tropics many scorpaenids are found in association with coral; elsewhere most are found on rocky or rough bottoms. In both cases they are highly camouflaged to match their backgrounds. The sculpins, flatheads, and scorpaenids, although not fast or powerful swimmers, feed on many more active smaller fishes and crustaceans, usually capturing prey by a swift pounce using the large pectoral fins as auxiliary power units.

The dangerously venomous stonefishes

Cryptic (concealing) coloration is probably best exemplified by the stonefishes (*Synanceja*), inhabitants of shallow waters, including estuaries, mud flats, coral reefs, and coral sand pools of much of the tropical Indo-Pacific. Looking like a lump of eroded coral or rock, the stonefish's body is concealed by the cragginess of its outline and by its coloration, which exactly matches that of the background. A stonefish is perfectly hidden and makes no movement until prodded with a stick or, more often, until it is stepped on, at which time it erects its dorsal fin spines. Each spine has a pair of large gray-brown fusiform venom glands, one on each side. The spines inflict puncture wounds into which a considerable quantity of venom is injected through a channel on each side of the spine. Intense pain at the site of the puncture is instantaneous and radiates within minutes to involve the whole of the affected limb. Death occasionally occurs, and secondary infections are common.

Many other scorpaeniforms can inflict severe wounds with their fin spines or head spines, but relatively few species are equipped with venom glands. One group of venomous species includes the turkey fishes (*Pterois* and related genera), also known as lion fishes or fire-fishes. Widespread in tropical Indo-Pacific waters, they are beautifully and boldly coloured, with patterns of contrasting stripes on the head and body that are specific for individual species and extremely long dorsal and pectoral fins. All of these fishes have long, needlelike dorsal spines with glandular venom-producing tissue and shallow channels capable of inflicting very painful but rarely fatal punctures. The bold and distinctive colouring of the turkey fish is clearly a warning, for, unlike most scorpaenids, it does not hide but boldly swims in open water around the coral heads. If disturbed, the turkey fish displays by spreading its fins to their fullest extent, rotating until it assumes a position, often head down, with its dorsal spines pointing toward the intruder. If an attacker is not intimidated by this display, the turkey fish moves toward the attacker with its dorsal spines erect.

The flatheads (Platycephalidae) are found in the same oceans as the scorpaenids but mainly in sandy, muddy, or estuarine areas. Their greatly flattened bodies are clearly an adaptation to bottom life; indeed, they bury themselves on the bottom, leaving only the eyes exposed. Many species feed mainly on small fishes, but others, like the dusky flathead (*Platycephalus fuscus*), the largest and commercially most valuable of the Australian flatheads,

From B W Halsted, *Poisonous and Venomous Marine Animals of the World;* U.S Detense Department

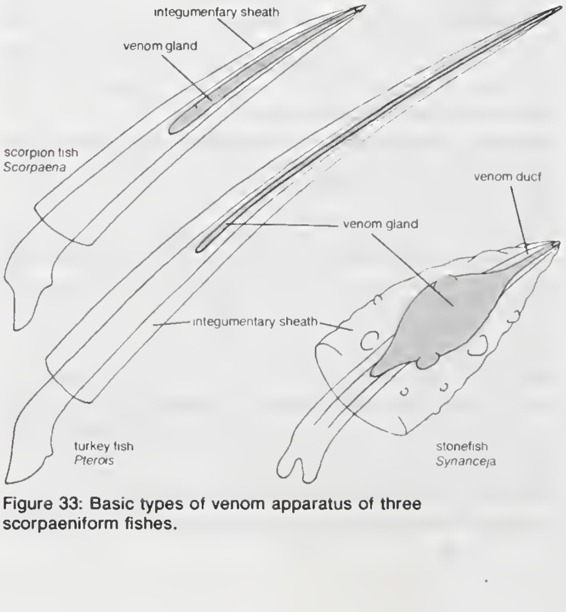

Figure 33: Basic types of venom apparatus of three scorpaeniform fishes.

have a varied diet of fishes, mollusks, crustaceans, and marine worms.

Adaptations for bottom living in sea robins

The sea robins (Triglidae) are bottom-living fishes of wide distribution. The lower two or three pectoral fin rays, which are long, thickened, and detached from the remainder of the fin, form organs of taste and touch and are used for locomotion. These rays are very mobile, and an active sea robin can move slowly along the bottom apparently supported on the rays, which continuously explore the ground ahead and on either side. The diet of most of these fish consists of crustaceans, mollusks, and other fishes, many of which burrow in the seabed.

The most abundant littoral (shore) scorpaeniforms are the sculpins (Cottidae), significantly the only group found in fresh water, other than the closely related families Cottocomephoridae and Comephoridae. Some members of the families Scorpaenidae and Cyclopteridae are also littoral fishes. The littoral sculpins are generally small, inhabiting densely weeded pools or crevices in rocks. Both the sculpins and cyclopterids found along the shore are strongly thigmotactic (attracted to surfaces), pressing as much of their bodies to the surface as possible. The cyclopterids have well-developed sucker disks, which are derived from the pelvic fin complex. The suckers, which are effective in resisting wave action, are capable of exerting considerable force; in one instance, a force of 13.3 kilograms (approximately 29 pounds 5 ounces) was required to break the hold of an adult lumpsucker (*Cyclopterus lumpus*). The European littoral sea snail (*Liparis montagui*) can vary the suction exerted by its sucker as necessary to adjust for the speed of passing water currents.

The cyclopterids have adopted a wide variety of lifestyles in addition to the littoral habit. The genus *Nectoliparis* is pelagic (*i.e.*, inhabiting open water); members of the genera *Paraliparis* and *Rhodichthys*, of the North Pacific and Arctic Oceans, are bathypelagic, at least for a large part of their lives. In fishes found at depths of 2,400 metres (7,900 feet), the pelvic sucker disk is completely absent. In the semitransparent but beautifully pink-tinged species of the genus *Careproctus*, found in deep, cold polar waters, the pelvic sucker is greatly reduced in size and presumably in efficiency.

In contrast to the cyclopterids, the greenlings are pelagic fishes that adopt a benthic (bottom) life only during the spawning season. One of the best-known members, the Atka mackerel (*Pleurogrammus monopterygius*), which is common in the North Pacific and has considerable sporting and commercial fishing value, spends the major part of its life in the open sea. The related yellow-fish (*P. azonus*) has been observed in the upper layers of the ocean in calm weather and is usually captured in purse seines. At night it descends to the bottom.

The scorpaeniforms have adapted particularly well to fresh water. The members of the sculpin family (Cottidae) are widely distributed in the Northern Hemisphere, reaching their greatest diversity in North America and decreasing in number westward through the Eurasian landmass. In extreme western Europe there is only one species, the miller's thumb (*Cottus gobio*). Two endemic forms, *C. kneri* and *C. kessleri*, both of some commercial importance, are found in Lake Baikal, Russia, and its tributary rivers. These species share Lake Baikal with a number of other species belonging to the related families Cottocomephoridae and Comephoridae. The sculpins in Lake Baikal have become adapted to exploit all of the living space offered by this inland sea. The family Cottocomephoridae is divided into eight genera and numerous species. Although many of the benthic species are restricted to a particular type of bottom and are found only within a certain depth range, most migrate into coastal waters in the spring and remain there during the warm season. Some species, however, remain in deep water all year; others, which are primarily pelagic fishes, use the bottom only to spawn.

Diversity of sculpins in Lake Baikal

The two members of the family Comephoridae, called Baikal cods (*Comephorus baicalensis* and *C. dybowskii*), are pelagic fishes, the latter living at depths to 1,000 metres (more than 3,000 feet). The feeding habits of these Baikal cottoid fishes all exploit potential food resources; the pelagic species feed mainly on various pelagic crustaceans and make daily vertical migrations accompanying their prey, and the benthic forms feed chiefly on certain species of benthic copepod crustaceans. The diet of one inshore species, *Batrachocottus nikolskii*, however, is mainly chironomid and caddisfly larvae.

Reproduction. The mail-cheeked fishes are highly variable in their mode of reproduction. Some of the methods used by them to reproduce are noted below. In the Comephoridae there is a remarkable imbalance between the numbers of each sex, the proportion of males in the total population being as low as 3 or 4 percent. The biological basis for this imbalance is unknown. Members of this family are viviparous (live-bearing). The females come near the surface to give birth to their young; the males remain at their normal depths. By contrast, the remaining cottoids are oviparous (egg-laying), including the Cottocomephoridae of Lake Baikal. The females of most of the latter family deposit their eggs in shallow coastal water, then leave the males to guard them until they hatch. This is also the general rule among the sculpins, in which the males guard the eggs. In some species the eggs are shed loosely and adhere to the bottom, but little reliable evidence is available concerning the breeding habits of most cottoid fishes. The northern Atlantic short-horned sculpin, or bullrout (*Myoxocephalus scorpius*), is known to build a rudimentary nest guarded by the male, as does the freshwater European miller's thumb. The males of these and other cottids have a well-developed structure called a urogenital papilla, which some authorities have suggested is used to introduce sperm into the female. Many cottoid species develop pronounced breeding coloration with sexual differences that apparently aid in recognition between the sexes and in territorial behaviour.

Specialized behaviour

Some members of the family Cyclopteridae build nests that are guarded by the male. The familiar lumpsucker, or sea hen (*Cyclopterus lumpus*), common on both sides of the North Atlantic, spawns along the coast in the winter. At least some of the inshore species, such as the striped sea snail (*Liparis liparis*), which has a distribution similar to that of the lumpfish, deposit their spawn in clumps on hydroids (*e.g.*, sea moss) and seaweeds, but there is no evidence of parental care. The females of some North Pacific cyclopterids (*e.g.*, *Careproctus sinensis*) have a long specialized structure (ovipositor) by which they lay their eggs under the shell of the Kamchatka crab. In general, however, little is known about the breeding biology of these fish.

In contrast to the rather specialized reproductive behaviour of the sculpins and the sea snails, the sea robins produce eggs that are simply shed in batches in the open sea. So far as is known, no special breeding behaviour accompanies spawning except that these noisy fishes become increasingly loquacious during the spawning season. The members of the family Hexagrammidae (the Atka mackerel, for example) deposit one clump of eggs, often on algae in shallow water on stony bottoms; some species, however, like the lingcod (*Ophiodon elongatus*), care for their egg masses during incubation. The sea poachers, or pogges (Agonidae), lay relatively few eggs, often hiding them away in crevices. The eggs are relatively large, 1.5–1.9 millimetres (roughly $^1/_{16}$ inch) in diameter in *Agonus decagonus*, a species found in the extreme North Atlantic. The European hook-nose (*Agonus cataphractus*) lays up to 2,400 eggs inside the hollow rhizoid ("stalk") of the kelp *Laminaria* in a compact, membrane-covered mass. Incubation is prolonged, possibly as long as 12 months.

Scorpion fishes of the family Aploactinidae similarly shed their eggs in the open sea. Members of the scorpaenid subfamily Scorpaeninae extrude eggs in gelatinous balloon-shaped masses; those in the subfamily Sebastinae have internal fertilization and are viviparous. The three groups represent the principal evolutionary stem groups of the scorpion fishes. In the North Atlantic redfish (*Sebastes marinus*) fertilization is internal, and the eggs develop within the oviduct of the mother. Fertilization usually takes place during February, after which the females form shoals and migrate to spots where warm bottom currents pass. The female can be said to be a living incubator; in such fishes, which live in cold northern seas, it is clearly advantageous to carry the developing young to an area in which more favourable conditions prevail. The young at birth are very immature, nevertheless, and brood size in the redfish is relatively large (up to 360,000); the larvae must survive a lengthy planktonic life. A smaller, shallower water redfish, the Norway haddock (*Sebastes viviparus*) produces much smaller broods, with brood sizes ranging from 12,000 to 30,000 young. The scorpaeniforms are distinguishable among viviparous teleosts (advanced bony fishes) by their comparatively high fecundity; comparison with many other marine fishes, single individuals of which produce millions of freely shed eggs, however, illustrates the relative advantage, at least in numbers, of bearing living young over laying eggs.

Differences in numbers of offspring

The North Pacific redfishes or rockfishes (*e.g., Sebastodes, Sebastiscus,* and *Hosukius*) closely resemble the North Atlantic sebastine species in their reproductive biology; all species studied have been found to have relatively large brood sizes. The sebastine rosefishes (*Helicolenus*), found in both the northern Atlantic and Pacific Oceans, have morphological affinities with the subfamily Scorpaeninae. Studies of their reproductive biology have shown that the sebastine rosefishes have intraovarian embryos embedded in a gelatinous matrix, and they thus appear to combine sebastine viviparity with scorpaenine egg masses.

Sound production. Since the time of Aristotle, the sea robins have been known as sound-producing fishes, and their sonic performances and mechanisms are well known. They have a large swim bladder loosely attached to the dorsal wall of the body cavity; the swim bladder is vibrated by lateral muscles in which the striated fibres run at right angles to the muscles' length. The sea robin of the North Amerian Atlantic coast (*Prionotus carolinus*) produces single vibrant barks and growls, as wells as series of rapid clucks with very little provocation. Some of the sculpins (Cottidae) produce dull groans and growls; it is believed that these sounds are mechanical in origin, arising from contractions of the muscles that produce periodic movements of the pectoral girdle. Flying gurnards (Dactylopteridae) are similar to the triglids in their sonic mechanism and sound production capacity.

FORM AND FUNCTION

General features. Many mail-cheeked fishes, such as the rockfishes, have simple fusiform (spindle-shaped) body plans, but others, such as some sea poachers, are extremely slender. Most scorpaenids, triglids, and cottids have two dorsal fins (sometimes joined), the forward one supported by stiff spines. In general, the dorsal, anal, and pectoral fins are large, sometimes strikingly so, but in some groups (*e.g.,* cyclopterids) the spinous dorsal fin is reduced or absent.

The uniting feature of the order

The one feature diagnostic of the order is the presence of a bony bar, or stay, beneath the eye, an extension of the second infraorbital bone. It is small and inconspicuous in some primitive scorpaeniforms and secondarily reduced in some specialized forms; in others, however, it is readily evident. Often it has become externally prominent, bearing protrusions or spines, or has expanded and fused other cranial bones bones to form a hard armour.

Camouflage and coloration. Many scorpaeniform fishes, such as scorpion fishes, rockfishes, and sculpins, which live on coral or rocky bottoms, possess a remarkable degree of cryptic (concealing) coloration and shape. Numerous fleshy lappets adorn the head, fin membranes, and body scales, rendering the fish virtually invisible against a background of rocks covered with marine organisms. The effectiveness of this camouflage cannot be appreciated unless the fish is viewed in its natural habitat.

Some members of the order, such as the sea robins, are notable for brilliant colours, especially reds. The large pectoral fins are often strikingly coloured; in the European tub gurnard (*Trigla lucerna*) they have spots of bright green and peacock blue. The spots on the pectorals of the flying gurnards resemble eyes and apparently function to startle and frighten potential predators when the fins are suddenly spread. The brightly coloured fins of some sea robins may function in a similar manner.

CLASSIFICATION

Annotated classification. The following classification is modified from that suggested by British ichthyologist P.H. Greenwood and the Americans S.H. Weitzman, D.E. Rosen, and G.S. Myers.

ORDER SCORPAENIFORMES (mail-cheeked fishes)
Spiny-finned fishes generally with stout bodies. Second infraorbital bone united with the preopercular to form a rigid stay across the cheek. Pelvic fins thoracic in location (sometimes modified into sucker disks), the bones directly attached to cleithra (bones like the collarbones of higher vertebrates).

Suborder Scorpaenoidei
Moderate-sized fishes with 24 to 40 vertebrae. Anterior ribs absent or sessile (rigidly attached). Numerous species.

Family Scorpaenidae (scorpion fishes and redfishes)
Paleocene to present. Marine fishes widely distributed in tropical, temperate, and northern seas. Perchlike appearance, dorsal fin spines long and numerous; head spiny, body scaly. Locally important food fishes, some with venom glands on fin spines. Size to around 100 cm (39 in.).

Family Triglidae (gurnards and sea robins)
Upper Eocene to present. Marine fishes of warm and temperate seas. Characterized by rather slender form, body with small scales or bony plates; head heavily armoured. Lower pectoral fin rays separate, forming a tactile organ. Locally exploited by man as food. Size to around 70 cm (28 in.).

Family Synancejidae (stonefish)
Tropical Indo-Pacific. Scaleless, body covered with warty tubercles. Venom glands on fin spines; dangerously venomous. Size to around 60 cm (24 in.).

Families Aploactinidae, Pataecidae, and Caracanthidae
Tropical Pacific, often in coral. Small scaleless fishes (except Caracanthidae, which have dense dermal papillae). Size to about 25 cm (10 in.).

Suborder Hexagrammoidei
Moderate-sized, slender-bodied fishes. Vertebrae 42–64. Ribs attached to strong parapophyses (projections of vertebrae). Few species, midwater and benthic.

Families Hexagrammidae (greenlings), *Anoplopomatidae* (skilfish), *and Zaniolepididae* (comb fishes)
Northern Pacific. Small scales, long dorsal fins, spines on the head few, powerful teeth in jaws. Locally important food fishes, some with sporting value. Size of most to about 45 cm (18 in.), some longer.

Suborder Platycephaloidei
Moderate-sized with head and anterior part of body strongly flattened. Vertebrae about 27. No air bladder.

Family Platycephalidae (flatheads)
Head and body flattened anteriorly. Marine; usually buried in soft bottom, some forms on coral; Indo-Pacific and tropical eastern Atlantic. Important commercial fishes in Southeast Asia, tropical Australia, and elsewhere. Size to 130 cm (52 in.) and 15 kilograms (33 pounds).

Suborder Hoplichthyoidei
Small fishes, with very depressed bodies. Scaleless, but body with bony plates. Head with heavy spiny ridges.

Family Hoplichthyidae
Found in moderately deep water in Indo-Pacific region. Size to 25 cm (10 in.).

Suborder Congiopodoidei
Moderate-sized fishes with angular bodies and well-developed dorsal fin spines. Scaleless, but sometimes rough skins.

Family Congiopodidae (horse fishes)
In moderately deep cold waters of Southern Hemisphere, off South America, Australia, and South Africa. Size to 75 cm (30 in.).

Suborder Cottoidei
Small to moderate fishes. Marine, from temperate to polar seas, and freshwater in Northern Hemisphere. Mostly without scales; many with spiny skins, others with bony plates. Many species.

Family Cottidae (sculpins and bullheads)
Oligocene to present. Generally large headed, with well-developed head spines. Marine and freshwater of the Northern Hemisphere (1 genus said to occur in the Tasman Sea). Mostly small, some up to 60 cm (24 in.).

Families Cottocomephoridae and Comephoridae
Similar to cottids but postcleithral bones absent or rudimentary. Freshwater, endemic to Lake Baikal, Russia. Size to about 16 cm (6 in.).

Family Icelidae (two-horn sculpins)

Head large, laterally compressed, and with small spines. Lateral line and dorsal fin base with scutes (plates). Small benthic fishes mainly of North Pacific, a few in the North Atlantic. Size to 25 cm (10 in.).

Family Normanichthyidae

Head and body with ctenoid (fringed) scales; head withoui spines. Two well-separated dorsal fins, soft fin rays branched. Marine waters off Chile. Size to 11 cm (4 in.). Probably does not belong in order Scorpaeniformes.

Family Cottunculidae

Body covered in loose skin covered wiih bony tubercles. Head large, lacking spines. Deep waters of the Arctic and North Atlantic oceans, Indian Ocean off South Africa, and Flores Sea, Indonesia. Size to 20 cm (8 in.).

Family Agonidae (poachers and pogges)

Eocene to present. Body covered in hard armour of large scutes. One or two dorsal fins. Teeth minute. Small, benthic, coastal fishes of northern Pacific, Atlantic, and Arctic oceans and Antarctic waters. Size to 30 cm (12 in.).

Family Cyclopteridae (lumpfishes and sea snails)

Body short, ihick, tadpole-shaped. Skin thick, naked or with bony tubercles or small thorns. Two dorsal fins, the first often minute or modified. Pelvic fins forming a sucker disk or absent. Marine, from littoral to abyssal depths (4,000 metres) in northern Atlantic and Pacific oceans, Arctic and Antarctic waters. Size to 60 cm (24 in.); 5.5 kg (12 lb).

ORDER DACTYLOPTERIFORMES

Resemble Triglidae. Head covered by bony plates ihat are expanded into huge shields. First infraorbital bone connected to preoperculum. Pectoral rays long, numerous, and brightly coloured.

Family Dactylopteridae (flying gurnards)

Tropical and warm temperate regions of Atlantic and Indo-Pacific oceans. Few species. Size to 50 cm (20 in.).

Critical appraisal. The classification of the scorpaeniforms cannot be said to have approached a final synthesis. It has been suggested that they are an aggregation of three distinct evolutionary lines, the two dominant elements being the scorpaenid and cottid-hexagrammid lines, the third, and minor, group being the anoplopomatids. On the other hand, British ichthyologist P.H. Greenwood and colleagues have pointed out that all members of the order, as recognized here, share a distinctive type of caudal (tail) skeleton. The order Scorpaeniformes is clearly related to Perciformes within a superorder Acanthopterygii.

The systematic positions of some groups remain open to doubt. The flying gurnards have been placed by some workers in the Scorpaeniformes, and, indeed, the morphological and biological resemblance of the flying gurnards to members of the Triglidae suggests that such placement best expresses their phyletic affinities. (A.Wh.)

Perches, tunas, marlins, and allies (Perciformes)

The order Perciformes, the perchlike fishes, is the largest group of fishes in the world today, comprising more than 6,000 species that have been classified into about 150 families. Perciform fishes occur in abundance in both marine and freshwater areas of the world, ranging from shallow freshwater ponds to depths of more than 2,300 metres (7,500 feet) in the oceans. Most perciforms are marine fishes, generally found along coastal areas of tropical and temperate regions of the world. The order includes many of the world's most important food and game fishes, such as tunas, mackerels, bonitos, and skipjacks (family Scombridae), billfishes and marlins (Istiophoridae), swordfish (Xiphiidae), sea basses (Serranidae), and carangids (Carangidae), a large family that includes pompanos, jacks, cavallas, and scads. The freshwater food and sport fishes of the perciform order include the sunfishes (Centrarchidae) and the perches and walleyes (Percidae). Many perciforms are popular aquarium fishes.

GENERAL FEATURES

Size range. Perciform fishes vary greatly in size, ranging from the tiny freshwater goby *Pandaka pygmaea* (Gobiidae) of the Philippines, which is fully grown at about 1.2 centimetres (less than one-half inch) in length, to the black marlin (*Makaira indica*), swordfish (*Xiphias gladius*), and bluefin tuna (*Thunnus thynnus*), which attain lengths of about 3.3 metres (11 feet). The bluefin tuna and the Indo-Pacific black marlin have been known to exceed 680 kilograms (1,500 pounds) in body weight. Generally, most percoid fishes fall within the range of 30 to 250 centimetres in length.

Distribution. Perciform fishes occur worldwide and are clearly a highly successful group. The coral reefs of tropical seas abound with colourful perciforms, including such species as wrasses, butterfly fishes, gobies, damselfishes, blennies, and cardinal fishes. The perciform order comprises a large part of the fauna of the Indo–West Pacific region, which is probably the world's richest in the variety of its fish fauna. Of the Antarctic fish fauna, approximately 75 percent belong to the order Perciformes. These cold-water perciforms include the icefishes (family Channichthyidae [Chaenichthyidae]), known for their "bloodless" appearance, which results from the lack or near lack of red blood cells and blood pigments. Freshwater perciforms include the cichlids (family Cichlidae), which occur naturally in India, Africa, South America, and parts of southern North America; these fishes also have been introduced elsewhere. The perch and sunfish families are found in North America and Europe, and the European perch (*Perca fluviatilis*) occurs well north in Siberia.

Drawing by G Christman

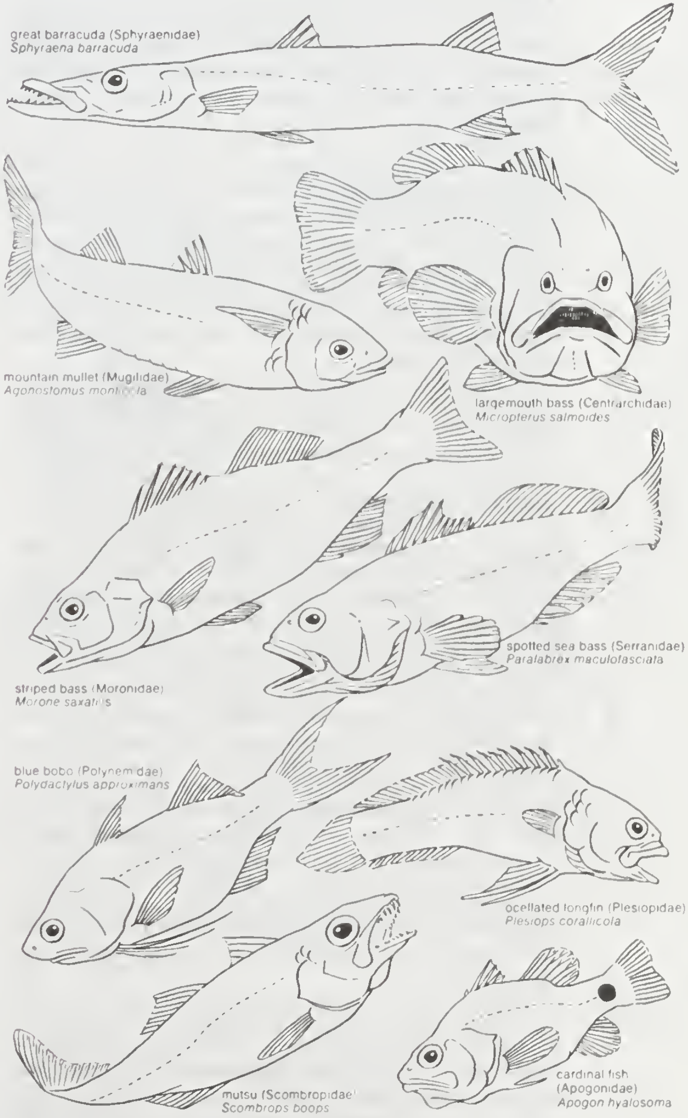

Figure 34: Representative perciforms of the families Sphyraenidae, Mugilidae, Polynemidae, Scombropidae, Apogonidae, Moronidae, Serranidae, Plesiopidae, and Centrarchidae.

IMPORTANCE

Use as food. Since early times, the rivers and oceans have provided man with food; fishing was one of man's earliest means for securing food. Archaeological findings among shell mounds of Scotland indicate that the sea bream (family Sparidae) formed part of the diet of early man. The Nile perches (family Latidae) have been found as mummies in ancient tombs in Egypt. The goatfishes (family Mullidae) appear in ancient Roman archives as one of the most highly valued food fishes, and in Japan the goatfish holds a good market and is eaten raw as *sashimi* or in the form of dried fish cakes known as *kamaboko.* In Japanese art through the ages, the fish god is shown with the "king of sea fish" under one arm; this highly valued food fish is the porgy *Chrysophrys major* (family Sparidae). A Japanese New Year's dinner usually includes *buriko,* the eggs of the sandfish *Arctoscopus japonicus* (family Trichodontidae).

The perciform fishes play an important part in commercial fisheries all over the world. Isinglass, which is used in the production of jellies and also in the process of clarification of wine and beer, is obtained from fishes that include the drums (family Sciaenidae) and the threadfins (family Polynemidae). The skin of the wolffishes (family Anarhichadidae) provides a leather of fair quality. The guanin present in the skin of the Japanese cutlass fish (*Trichiurus;* Trichiuridae) is used in the manufacture of artificial pearls in Japan.

Breeding and cultivation of perciforms has been successful in many parts of the world. The African mouthbreeder (*Tilapia macrocephala,* Cichlidae) has been successfully introduced in many areas and is valued for its rapid rate of reproduction and growth, providing a source of low-cost protein.

Aquarium fishes. Colourful and interesting perciforms are kept for aesthetic reasons by aquarists, augmenting an industry partially supported by fishes of other orders. Popular aquarium fishes of the perciform order include cichlids, butterfly fishes (Chaetodontidae), angelfishes (Pomacanthidae), labyrinth fishes (suborder Anabantoidei) such as the Siamese fighting fish (*Betta splendens*) and the kissing gourami (*Helostoma temmincki*), and various gobies (Gobiidae), blennies, and blennylike fishes of the suborder Blennioidei.

The freshwater angelfish *Pterophyllum scalare* and the discus (*Symphysodon discus*) are among the most popular aquarium fishes for breeding because of their remarkable means of feeding their young on the mucous secretions of their bodies.

Danger to human life. A few of the perciforms are known to be harmful to man. Swimmers have been attacked by the barracuda (*Sphyraena*), which is a voracious fish reaching nearly two metres (six feet) in length. Perciforms possessing venom glands are also considered dangerous fishes. The dorsal spine of the weever fishes (Trachinidae) has a grooved structure containing a venom gland; in addition, there is also a stinger located on the opercular (gill cover) structure. Both the stinger and the dorsal spine can be extremely painful if stepped on in shallow waters. Similar venom-bearing structures are found in the dragonets (Callionymidae) and surgeonfishes. The venomous spines in the surgeonfish are located on either side of the caudal peduncle (the narrow stalk just in front of the tail). Especially well armed are the electric stargazers (*Astroscopus,* Uranoscopidae), which are capable of discharging up to 50 volts of electricity from the modified muscle tissue just posterior to the eyes; in addition, they possess a venom spine just above the pectoral fins. The venom from uranoscopids has been known to cause death in man.

Poisonous perciforms

Ciguatera fish poisoning has been attributed to some perciforms that are otherwise considered to be excellent food fishes. Among these are certain carangids, snappers, barracudas (Sphyraenidae), surgeonfishes (Acanthuridae), groupers, and porgies. A species completely edible in one area may be poisonous in an area just a few hundred miles away. This curious phenomenon has not yet been fully explained, although it has been suggested that the source of poisoning may be a toxic form of blue-green alga passed up the food chain and thus present in the food of toxic species.

NATURAL HISTORY

Life history. Many perciforms live out their whole lives in small areas, but others, especially open-ocean (pelagic) species, perform extensive migrations, about which much remains to be learned. Some marine serranids, however, are anadromous (*i.e.,* entering fresh or brackish water to spawn); some freshwater perciforms, such as certain species of gobies, enter the sea to spawn (catadromous). Tuna (Scombridae) may travel across the entire Pacific Ocean from the California coast to Japan or the reverse. Spawning in perciforms generally takes place in shallow coastal areas or in rivers and ponds among rocks, seaweeds, and aquatic plants. *Paraclinus marmoratus,* a clinid blenny, is known to lay eggs at times in the lumen (cavity) of a living sponge.

Breeding behaviour among fishes of the order Perciformes is diverse. Pairing of male and female is common, although a single female may pair with more than one male, as among certain serranids, perches, and cichlids. The sexes are usually distinct, but hermaphroditism (presence of functional male and female organs in a single individual) normally occurs among certain sea basses and porgies. The young of the black sea bass (*Centropristis striata*) are mostly females with normal egg-laying functions; after five years, however, some of these females transform into functional males. About 11 species of sparids have been found to display hermaphroditism at one time or throughout their lifetime.

Differences in appearance between sexes

Characteristic differences usually exist, especially during the breeding season, between sexes regarding colour, size, markings, or structure. The male is generally smaller in size (some exceptions are found in sunfishes, gobies, and

Drawing by G. Christman

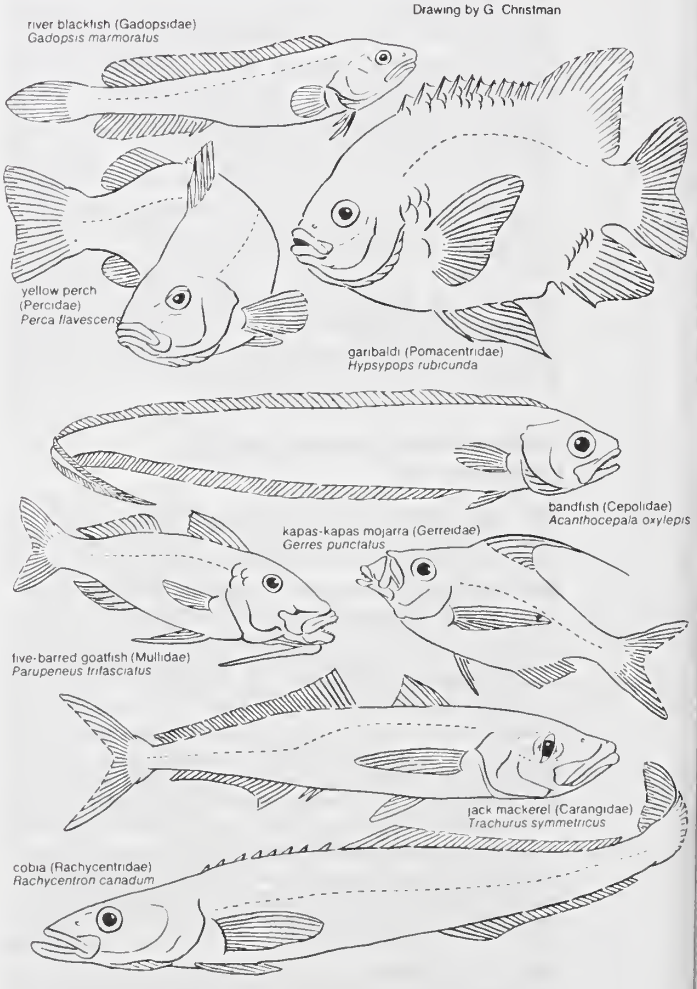

Figure 35: Representative perciforms of the families Pomacentridae, Percidae, Cepolidae, Mullidae, Gerreidae, Carangidae, Rachycentridae, and Gadopsidae.

blennies) and has brighter coloration of the fins and body. Black, white, green, red, blue, and silver are colours characteristic of the brightly coloured males of damselfishes (Pomacentridae), wrasses (Labridae), labyrinth fishes, and cichlids. Structural differences between the sexes vary from easily observed characteristics, such as the presence of a longer dorsal fin in the male dragonets, to less obvious characteristics, such as larger canines in the dentition of male blennies (Blenniidae) and gobies. Bands, blotches, and tinged markings may also be characteristic of the brighter coloured males, as in some wrasses. During the spawning season, males of certain species of cichlids, parrotfishes (Scaridae), sparids, and wrasses develop a swelling on the forehead that may persist throughout life. These characteristics presumably enhance the male in its breeding and courtship activities.

Little is known of the courtship activities in most marine species of perciforms. Among those that have been studied, the male dragonet, with extended fins and gill covers, performs a display of colours while swimming repeatedly around the female. A similar courtship activity is also carried out by the fighting fishes (*Betta*).

Fertilization is usually external, although internal fertilization, in which the eggs are fertilized within the body of the female, is well known in such groups as surfperches (Embiotocidae); and the male in such cases generally possesses an intromittent organ, which functions in the transfer of sperm to the female. Internal fertilization also occurs among some of the gobies, clinid blennies (Clinidae), and apogonids. Perciforms that undergo internal fertilization mostly are viviparous; *i.e.,* they give birth to live young. The number of young in viviparous perciforms varies from three to 50 in the surfperches. The larger viviparous forms, however, have been found to produce a greater number of young.

Nest-building behaviour

Most perciform fishes are oviparous—*i.e.,* they lay eggs that are fertilized externally. The number of eggs laid varies from a few hundred to more than 3,000,000 in a 32-pound (15-kilogram) yellowtail (*Seriola dorsalis,* Carangidae). Often, the eggs are released to float freely, but many species have evolved elaborate nest-building behaviour. Nest construction frequently consists merely of clearing away of a small area under rocks, which may be on the open bottom or even inside empty animal shells. The sunfishes and darters (Percidae) use their fins or body to dig a circular depression for use as a nest. Wrasses construct a nest out of stones, shells, and seaweed. Males generally undertake the task of building the nest, but in many cases both male and female share the labour.

Most labyrinth fishes build bubble nests, the procedure being similar among members of the family. The male Siamese fighting fish takes a bubble of air into his mouth, coats it with a mucous secretion, then blows the coated bubble to the surface; this process is repeated until a bubble nest is formed. After pairing, the female allows the fertilized eggs to drop to the bottom, where the male picks them up in his mouth and blows them into the bubble nest. Many marine perciforms produce pelagic eggs (*i.e.,* that float on or near the surface of the open sea). Almost all of the freshwater perciforms produce demersal eggs (*i.e.,* that sink to the bottom). A certain amount of adhesiveness in the demersal eggs keeps the eggs together in clusters; the elongated shape of the clusters of perch eggs helps in securing the clusters to aquatic plants and rock bottoms. Not all eggs become attached to aquatic plants and other objects; the mature male humphead (Kurtidae) possesses a hooked structure on his forehead, to which the cluster of eggs is attached as soon as the female produces them. Oral incubation, in which the eggs are held in the mouth of one of the parents, is found in certain species of cardinal fishes (Apogonidae), jawfishes (Opisthognathidae), labyrinth fishes, and cichlids. The male, female, or both may incubate the eggs orally until they hatch, after which the young may be mouthbreeders. Similarly, guarding of the nest sites may be undertaken by the male, female, or both parents; however, males of some sunfishes, darters (*Etheostoma*), and the Siamese fighting fish defend their nest against intruders. In addition to guarding the nest, certain perciforms also aerate the eggs by directing a flow of water into the nest with fanning movements of the fins.

Although there is no evidence of parental care in perciforms that produce pelagic eggs, a strong protective behaviour is shown by most perciforms that build nests or carry their eggs around with them. The male dwarf cichlid may help in the care of the young, but it is the female that looks after the eggs, removing dead eggs from the clutch. In certain other cichlids (*Apistogramma* species, for example) the female may help free the young from the eggs by gently chewing off the egg shells. The young of many cichlids follow their mother around and quickly enter her mouth should danger threaten. The discus and the freshwater angelfishes of the cichlid family feed their young on mucous secretions of their own bodies. The male Betta guards the young until they can swim away freely on their own.

Threat displays of gobies and blennies

Behaviour. *Territorial activity.* Territorial behaviour is found in many perciforms, especially during the breeding season, when the male, and in some cases the female, displays territorial behaviour in guarding the nest of eggs or the young; such fishes include certain cichlids, sunfishes, and darters. The young tigerfish (Theraponidae) protects a restricted area around a small hole dug by using its body; such territorial behaviour disappears when the tigerfish grows beyond a length of about nine centimetres ($3\frac{1}{2}$ inches). An intruder approaching the burrow of a jawfish is usually greeted by a threatening pose of flared gill covers and erected fins. Gobies and blennies are also known for their marked territorial display; peck order may be present among gobies holding territories, with the highest degree of competition between male gobies of the same size. The characteristic threats of gobies and blennies include flaring gill covers, gaping jaws, puffing of throats, head raising, and shaking of bodies. When threat displays

Drawing by G. Christman

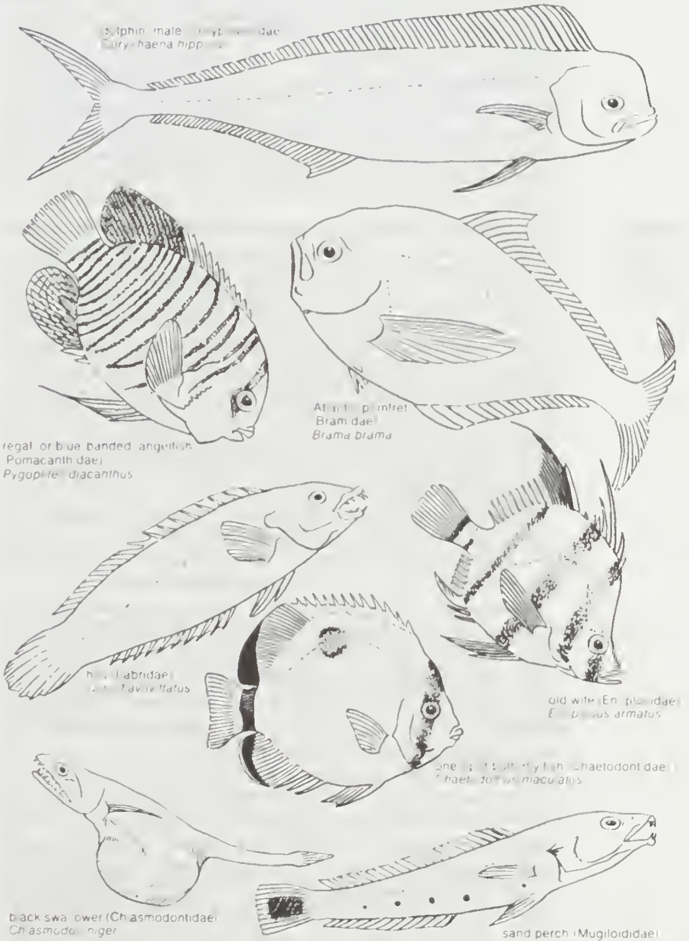

Figure 36: Representative perciforms of the families Coryphaenidae, Bramidae, Pomacanthidae, Enoplosidae, Chaetodontidae, Labridae, Mugiloididae, and Chiasmodontidae.

fail to settle a territorial dispute, male gobies fight, biting and chasing each other.

Sound production. The significance of sound production among perciform fishes is not well known, but most acoustic activity seems to be related to feeding and spawning periods. The level of sound production in croakers (Sciaenidae) increases considerably in the spawning season during the hours of late evening. There is also a difference in level between day and night; this may result from their feeding time. Damselfishes produce clicking sounds during feeding time, grinding the pharyngeal teeth. Another type of sound produced during feeding can be heard when parrotfishes feed on plant material covering reefs, biting on coral with their powerful platelike teeth. Grunts produce sounds by grinding their upper and lower pharyngeal teeth; the sounds are in turn amplified by the air (swim) bladder. Croakers, however, produce sounds by vibrating muscles of the abdomen that are attached to the sides of the air bladder, amplifying the vibrations of other muscles. The tigerfishes, or grunters (Theraponidae), have a similar system for sound production.

Feeding behaviour. Perciforms include both predator and prey species and are thus of great importance within the ecological food chains. The diverse adaptations for feeding are partly responsible for the success of this abundant order. Many of the colourful perciforms that occur around coral reefs are herbivorous fishes, the food of which consists mainly of plankton, algae on corals, and other reef vegetation; such fishes include parrotfishes, damselfishes, butterfly fishes, rabbitfishes and surgeonfishes. Among freshwater perciforms, certain species of *Tilapia* depend on aquatic plants for food. Most freshwater perciforms, however, are carnivorous, taking mosquitoes, insect larvae, and small insects. The larger predatory perciforms, in both freshwater and saltwater, feed on smaller fishes and even on birds and small mammals. They occupy a higher position within the food chain; examples include barracudas, groupers, tunas, and billfishes. The dolphins (*Coryphaena*) use their speed to catch fast prey such as flying fishes (Exocoetidae). The bluefish (*Pomatomus saltatrix*, Pomatomidae) is known for its voracious feeding behaviour; it feeds on open-water schooling fishes and, for unknown reasons, will continue to kill food fishes after its hunger is satiated.

Feeding behaviour of archer fishes

An interesting means of securing food is seen in archer fish (*Toxotes*, Toxotidae). The structure of the mouth in the archer fish is modified to form a groove along the roof of the mouth, against which the tongue fits to form a tube. The fish is able to direct a drop of water with remarkable accuracy at insects clinging to vegetation above the water surface. Thus bombarded, the insects fall into the water where they are quickly seized. Similar but less powerful squirting behaviour is also found in the butterfly fish. Another interesting type of feeding behaviour is seen in an African cichlid, which practices lepidophagy, the eating of scales plucked from other fishes.

Some predators lie in wait for their prey instead of pursuing it. An outgrowth of the mouth of the stargazer (*Uranoscopus scaber*) acts as a lure for prey. Groupers are also known to lie in wait for prey among rocks.

Adaptations of the mouth and jaw structure are seen in many of the perciforms. The piscivorous nandids (Nandidae) and the leaf fishes (Polycentridae) have large protrusible mouths capable of taking prey two-thirds their size, and the deeply cleft mouth of the swallowers (Chiasmodontidae) permits them to pass prey larger than themselves into their highly distensible stomachs.

Interspecific relationships. Mutual relationships among species are found in many perciform fishes. The cleaner fishes of the wrasse genus *Labroides* (Labridae) are well-known for their role in the removal of parasites from larger carnivorous fishes. The larger fishes recognize the cleaner fish and will not devour it. They allow free passage into their cavernous mouths and gill chambers, in which the cleaner fish feeds upon leftovers and parasites. Each *Labroides* maintains a "cleaning station," which is visited regularly by larger fishes such as groupers, eels, jacks, and snappers. A relationship of a protective nature exists in the butterfishes (Stromateidae), the young of which are often found among the tentacles of jellyfishes; the fishes are immune to the stings of the jellyfishes. Fry of horse mackerel and tuna (Scombridae) have been also found among the tentacles of jellyfishes. A similar relationship is seen in the clown anemone fish (*Amphiprion percula*), which is found among the tentacles of sea anemones. The mucous substances secreted by the anemone fish protect it from the stinging cells of the sea anemone. Some anemone fishes seek out only one type of sea anemone; others do not show any species preference. The sleepers of the genus *Vireosa* (Eleotridae) are usually found close to rock oysters and clams, into which they quickly disappear when danger threatens. A similar relationship exists between certain sea cucumbers (sac-shaped echinoderms of the class Holothuroidea) and cucumber fishes (Carapidae). These fishes are found among starfishes, clams, and sea urchins, as well as sea cucumbers. Some are host specific and may even parasitize the host, as in the Florida cucumber fish (*Carapus bermudensis*), which seeks out a specific sea cucumber of the genus *Actinopyga*, within which the cucumber fish makes its home. At times *Carapus* also feeds on the internal organs of the sea cucumber; this does not really harm the host because it regenerates the lost parts.

The blind goby, *Typhlogobius californiensis*, depends entirely upon holes dug by the ghost shrimp (*Callianassa*) for a home, and is unable to live without its help. Other gobies are known to share holes with burrowing worms, pea crabs, and snapping shrimps.

Imitative resemblance among perciforms

Certain perciform fishes depend upon imitative resemblance for survival. Immature tripletails (Lobotidae) will turn on their sides and float on the surface of the water, resembling dead leaves; similar behaviour is found in the leaf fish *Monocirrhus polycanthus* (Nandidae). Some wrasses (Labridae) resemble green algae because of their body coloration, a mixture of white, green, and brown. A remarkable mimic is seen in the case of the sabre-toothed blenny (*Aspidontus taeniatus*), which mimics the cleaner fish *Labroides*. By resembling a cleaner fish, the blenny is able to approach other fishes and surprise them by rushing in to bite off a piece of fin (see MIMICRY). Similar mimicry also occurs in an East Indies species of blenny that mimics a wrasse, apparently for food and protection.

FORM AND FUNCTION

The nature and diversity of the perciforms make a general definition of the group difficult; the most common characters are found in the large families of sea basses, mackerels, perches, sunfishes, and others. Perciform fishes usually have spines present on their dorsal, anal, and pelvic fins. The dorsal fin is usually divided into two parts, with the first part supported by one or more spiny rays; these are believed to have evolved for defense purposes. The pelvic fins are usually present, directly below or a little ahead of the pectoral fins, and they are supported by one spine and five or fewer soft rays. This position of the pelvic fins gives the perciforms an advantage in manoeuvring over short distances. The pelvic fins are lacking in some perciforms; in others, such as gobies, they are united to form a cuplike sucker; and, in the gouramis, the pelvic fin may be drawn out into long filaments.

A diversity of mouth and jaw structure occurs in the perciforms; most of it is brought about by the various types of feeding behaviour. Perciforms usually have protrusible jaws; and in the leaf fishes and swallowers, the jaws are easily distensible. The protrusible jaw may have thick lips, as in the wrasses, or may possess fleshy projections, as in certain species of African cichlids. Weever fishes (*Trachinus*) and stargazers (*Uranoscopus*) possess jaws that are directed upward; the jaws help when capturing prey as they lie buried in the sand. The upper jaws are greatly prolonged in the swordfishes and billfishes; the significance of this feature is rather uncertain. Many of the perciform species that inhabit coral reefs have modifications of the snout and jaws; the butterfly fishes have a straight tubelike mouth for reaching food among coral crevices.

Other structures of the perciforms have also undergone modification according to the various types of feeding behaviour. Most of the piscivores possess numerous short, fine, and pointed teeth; *e.g.*, the perches and sea basses.

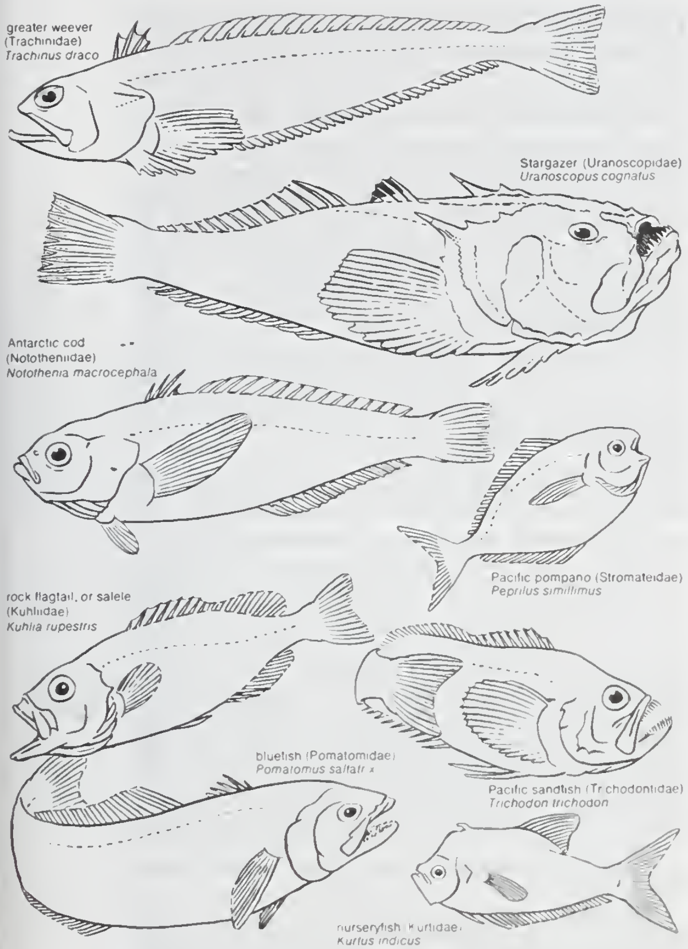

Figure 37: Representative perciforms of the families Kuhliidae, Pomatomidae, Trichodontidae, Trachinidae, Uranoscopidae, Nototheniidae, Stromateidae, and Kurtidae.

Drawing by G. Christman

Barracudas have long piercing canine teeth for holding and stabbing prey, and certain gobies and blennies characteristically have long, curved canines found in the lower jaw only. Perciforms that are either herbivorous or consumers of small invertebrates in addition to vegetation possess incisors, which are chisel-like teeth, as in certain sea breams; incisors may become fused into a beaklike structure, as in the parrotfishes. Enlarged pharyngeal (throat) teeth are present in some species of perciforms and are used for grinding and crushing hard-shelled food such as clams and snails. Tooth structure has undergone various modifications in many of the African cichlids. Herbivorous cichlids possess chisel-like teeth that are used to feed on plants and algae; the piscivorous ones have strong, pointed teeth. Cichlids that feed on the eggs and young of other species possess a highly distensible mouth with reduced teeth embedded in the gums. (M.W.L.)

CLASSIFICATION

Annotated classification. The classification presented here is mainly that of British ichthyologist P.H. Greenwood and colleagues, published in 1966; it in turn is fundamentally that established by the British ichthyologist C. Tate Regan in 1929. Certain changes have been incorporated, based mostly on characters from the nervous system.

All of the features distinguishing the order Perciformes are found in the fishes of the most generalized group, the suborder Percoidei, which contains the sea basses, sunfishes, perches, and fishes of many other families. As the subordinal name implies, the fishes composing it are "percoid," or perchlike in appearance. The fishes in the other suborders have presumably evolved from a percoid-like ancestor, but some have changed so much as to hardly resemble a percoid fish externally.

ORDER PERCIFORMES

Swim bladder not connected by an open duct to the throat; dorsal, anal, and pelvic fins usually with spines; dorsal fin usually with the first or anterior part supported by spiny rays and the rest by soft (articulated) rays, the spinous- and soft-rayed portions often separated from each other so as to constitute two distinct dorsal fins, or there may be a notch in the profile of the dorsal fin that indicates the two joined portions. A fin is considered long- or short-based on the basis of the length of its attachment to the body. Pelvic fins with 1 spine and 5 or fewer soft rays, or pelvic fins absent; pelvic fins thoracic in position (*i.e.*, placed ventrally below the base of the pectoral fins), pelvic fins sometimes ahead of pectoral fins (that is, jugular in position), or, occasionally, pelvic fins posterior to pectoral fins; pelvic girdle usually directly attached to base of pectoral girdle; caudal fin with not more than 17 principal (branched) rays supporting it; skull lacking orbitosphenoid bone; shoulder girdle lacking mesocoracoid bone; jaws typically protrusible; premaxillary bone of upper jaw excluding the maxilla from the gape of the mouth. Scales usually rough-edged (ctenoid), provided with small teeth (ctenii) along their posterior edge, sometimes round and smooth (cycloid). About 6,000 species, marine and freshwater; most species along shorelines in tropics and temperate zones, and in freshwater, the number of species dropping off drastically in higher latitudes. Fossil remains from the Upper Cretaceous Period (from 101,000,000 to 65,000,000 years ago).

Suborder Mugiloidei

Spiny-rayed dorsal fin rather widely separated from soft-rayed dorsal; pelvic fins of 1 spine and 5 rays, not thoracic but located more posteriorly on the abdomen; scaled lateral line with nerve pattern resembling that of some lower nonperciform fishes; taste nerves of trunk like many percoids; olfactory bulbs far forward, unlike other perciforms.

Family Mugilidae (mullets). Lower Oligocene to present; with a cigar-shaped, roundish body, short snout; large cycloid scales; usually numerous small movable teeth; muscular gizzard-like stomach in many species. Moderately large schooling fishes, 30 to 90 cm (1 to 3 ft) long. Less than 100 species; tropical and temperate waters, some in brackish water and some in fresh water.

Suborder Sphyraenoidei

Two dorsal fins, both short-based and widely separated from each other; pelvic fins some distance posterior to pectorals; pattern of trunk lateral line nerves in a rudimentary percoid pattern resembling pre-percoid patterns found in atheriniform fishes; pattern of taste nerves on trunk resembles that in atheriniform fishes; large teeth set in deep sockets.

Family Sphyraenidae (barracudas). Eocene to present; large, elongated, pikelike, with long, pointed jaws and big teeth; piscivorous; probably not over 120 cm (4 ft) long; all warm seas; about 20 species; fine game fishes.

Suborder Polynemoidei

Pelvic fins thoracic; pectorals low on side of body, divided into an upper normal part and an unusual lower part, consisting of a number of fin rays grown out into long sensory filaments, reaching to anal fin and far beyond in some species; pointed snout; large eyes.

Family Polynemidae (threadfins). Upper Miocene to present; resembling mullets in body shape and widely separated two dorsal fins, but like anchovies in ventral mouth with projecting snout, rather deeply cleft mouth, and adipose eyelids; in most warm seas, often abundant at river mouths and over sandy bottoms; about 24 species, most 30–69 cm (12–24 in.) long, but 1 giant species reaches 180 cm (6 ft).

Suborder Percoidei

The largest suborder both in numbers of families and in species; fishes typically of a perch or bass appearance; jaws protrusible; dorsal fin usually conspicuously spinous, often with the spinous and soft portions separated or nearly so or with a notch between them; anal fin with 2 or more spines at anterior end, occasionally with 1 spine, sometimes with more than 3 spines; pelvic with 1 spine and usually 5 soft rays; body often somewhat deep rather than elongated; territorial, bottom-oriented, investigative shorefishes with great close-quarters swimming manoeuvrability, swimming backward and forward short distances with much use of pectoral fins; great variety in adaptive design and operation of jaws; generalized predators of fishes and crustaceans in all warm seas near shores, especially in tropics; in freshwater. Almost 4,000 species, some of large size; about 90 families.

Superfamily Percoidea (basses, perches, sunfishes, cichlids, damselfishes, and many others).

About 60 families grouped together because they show no great morphological specialization away from the general bass, grouper, or perch kind of fish taken as a model. Most inhabit

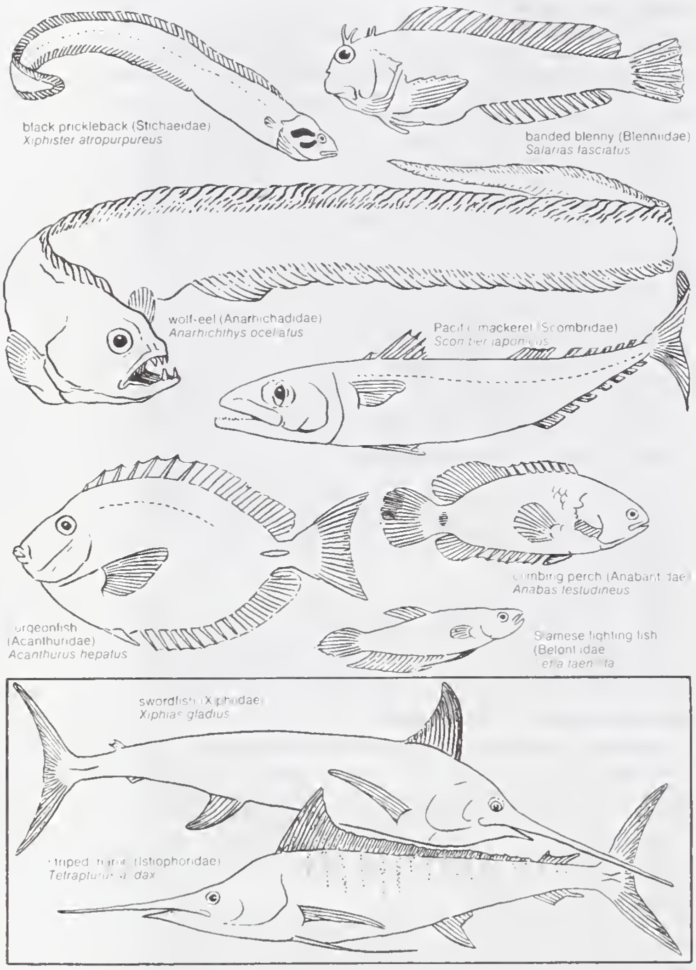

Figure 38: Representative perciforms of the families Blenniidae, Stichaeidae, Anarhichadidae, Acanthuridae, Scombridae, Xiphiidae, Istiophoridae, Anabantidae, and Belontiidae.
Drawing by G. Christman

shores of tropical and temperate seas or lakes. Two aspects most obviously contributing to the success of this group are the adaptability of the protractile mouth and the detailed variety of specializations for swimming manoeuvrability in restricted areas.

Family Scombropidae. Pliocene to present; rare, deep-water marine (down to 600–800 m, or 2,000–2,600 ft); this and the next several families retain some features that may have been those of the most generalized ancestors of present-day percoids such as: 2 dorsal fins separate, anal fin with 2 spines, primitive pattern of taste nerves on the body and remains of a special system of lateral line nerves on the head. About 7 genera and 20 species.

Family Acropomatidae. Rare, deep-water marine species similar to scombropids; anus located anteriorly from normal position at front of anal fin. Light organs present; midwater depths of 300–500 m (1,000–1,650 ft); 2 species; Indo-Pacific.

Family Apogonidae (cardinal fishes). Eocene to present; 2 well-separated dorsal fins; 2 spines in anal fins; midsection of body often short, with head, eyes, and caudal peduncle proportionately larger; mouth large. Males orally incubate eggs. Mostly marine species, often reddish; live around coral reefs in tropics and subtropics; nocturnal; a few species from deep oceanic midwaters 1,000–1,200 m (3,300–4,000 ft); most with special lateral line system of nerves and free organs well developed on head (among the few percoids with the system). About 200 species.

Family Moronidae (temperate basses). Eocene to present. Two dorsal fins connected at their bases. Most species slim-looking basses; well-known food and game fishes such as striped bass and white basses of the genus *Morone.* Some species anadromous. Weight to 50 kg (about 110 lb) in striped bass. About 12 species, marine and freshwaters of North America, Europe, Africa, Australia, and the Orient.

Families Pomadasyidae and Banjosidae (grunts). Eocene to present. Spinous and soft dorsal fins continuous, often notched. Resemble snappers (Lutjanidae), but teeth weaker, canines absent; sound produced by grinding pharyngeal teeth and amplified by adjacent swim bladder. Second anal spine often much enlarged; about 75 species, tropical and subtropical shorefishes, many entering estuaries; good food and game fishes.

Family Centropomidae (snooks or robalos). Eocene to present. Elongated, basslike fishes; head long and sloping; sizable mouth, projecting lower jaw; 2 separate short-based dorsal fins; short-based anal fin. Oceans and estuaries of Pacific and Atlantic coasts of tropical Americas; about 8 species, 45–150 cm (about 1 ½ to 5 ft); good food and game species.

Family Dinolestiidae. One species, resembling, but not related to, the barracudas (Sphyraenidae, above). Marine; Australia and Tasmania; length to 50 cm (20 in.).

Family Latidae (Nile perches). Eocene to present. Closely similar to Centropomidae. Piscivorous; freshwaters of Africa; at river mouths and along coasts in Southeast Asia and northern Australia; up to about 180 cm (6 ft) long and 140 kg (300 lb); excellent food fishes.

Family Percichthyidae (perch trouts). Eocene to present. Dull-coloured, small, perchlike freshwater and marine fishes of Chile and Argentina. Dorsal fin deeply notched. About 9 species.

Family Ambassidae (glass perches). Small fishes similar in body form to Apogonidae; body short, rather deep. Spinous and soft-rayed parts of dorsal fin nearly separated by deep notch. Good predators on mosquitoes; large schools in sea around river mouths and in freshwater; Indo-Pacific; about 24 species.

Family Serranidae (sea basses, groupers, and many others). Paleocene to present. Variously similar to many of the percoid families mentioned above in their general spiny-rayed, perchlike appearance. Dorsal fin continuous, but may be deeply notched; spinous portion of dorsal fin with longer base than soft dorsal portion; anal fin usually with 3 spines and short-based; no scaly sheath along base of dorsal and anal fins; mouth large; pectorals broadly rounded; caudal fin usually truncate or rounded, sometimes moderately forked. About 400 species in tropical, subtropical, and warm temperate seas; some in freshwater; good food and game fishes; maximum weight to about 320 kg (700 lb).

Families Pseudochromidae, Grammidae, Plesiopidae, Pseudoplesiopidae, and Acanthoclinidae. Quite similar, small, darkly colourful, rather secretive coral-reef basslike fishes of tropical Indo-Pacific and Caribbean seas. An interesting specialization of numerous species is the presence of multiple horizontal, interrupted lateral lines on trunk: 1 along the back, 1 along the side, and 1 along the bottom of each side of the body. Dorsal and anal fins vary from few or no spines up to 24; long dorsal fin, sometimes deeply notched between spines with a little banner or flag of fin membrane extending up and out from the end of the spine. Together, about 40 species.

Families Glaucosomidae (pearl perches) and *Lobotidae* (triple tails). Deep-bodied perchlike fishes found in eastern Pacific Ocean, except *Lobotes,* which also occurs elsewhere in tropical salt and freshwater; 5 or 6 species in Glaucosomidae; 1 in Lobotidae.

Family Priacanthidae (big eyes or catalufas). Eocene to present. Deep-bodied, reddish, serranid-like dwellers of deeper offshore waters, toward the bottom. Jaws almost vertically hinged; carnivorous. Tropical Indo-Pacific and Atlantic; few species; 30–45 cm (12–18 in.) long.

Family Centrarchidae (sunfishes and basses). Eocene to present. Moderately deep-bodied; spinous and soft dorsal fins continuous, not separate as in Percidae; more than 3 anal spines. Freshwaters of North America; only 1 species, *Archoplites interruptus,* native west of the Rocky Mountains; various species widely introduced elsewhere; prefer quieter waters, such as ponds, lakes, swamps; excellent game fishes; size from 30 gm (1 oz) to about 10 kg (22 lb); 30 species.

Family Embiotocidae (surfperches). Miocene to present. Laterally compressed, ovate, smooth-scaled, fairly small, with small head. One long dorsal fin, depressible into a scaled sheath alongside the fin. Give birth to actively swimming young; 23 species from central Baja California to Japan, absent from Aleutian chain; most species (20) occur in California; 1 freshwater species (*Hysterocarpus traski*) in central California; 12–30 cm (5–12 in.).

Families Nandidae and Polycentridae (near leaf fishes and leaf fishes). Small, mostly piscivorous fishes with large to huge protrusible mouths; consume prey up to $^2/_3$ their own length. Bodies moderate to deep, laterally compressed; long spinous dorsal fin and 3 to 13 spines in anal fin; soft dorsal and anal fins short-based and colourless, used together with colourless pectoral fin in *Polycentrus* and *Monocirrhus* in swimming imperceptibly toward prey without any evident signs of fin or body movement. Six species in freshwaters (and brackish for *Nandus*) from India to Malaysia; for Polycentridae, West Africa and the northeast coast of South America. Six species.

Family Cichlidae (cichlids). Eocene to present. Small freshwater (a few brackish water) percoids, resembling damselfishes (below) and North American sunfishes. One pair of nostrils instead of the 2 of most fishes; spinous dorsal fin long-based; anal fin short-based, 3-spined; dorsal and anal fins often pointed at posterior ends; caudal fin usually rounded; first pelvic rays of males often elongated; lateral line interrupted. Native to Texas, Central America, South America, and West Indies; Africa; Palestine, India, and Sri Lanka (formerly Ceylon). Complicated courtship, nest-building and mouthbrooding (several genera). Over 700 species, many of them important aquarium fishes; almost 600 native to rift lakes in Africa (especially Lakes Tanganyika, Nyasa, and Victoria); a few species up to 30 cm (12 in.); 1 up to 9 kg (20 lb; genus *Tilapia*).

Family Pristolepidae. A deep-bodied, laterally compressed, small-mouthed percoid, resembling a cichlid or pomacentrid but having a patch of blunt, molariform teeth on base of skull opposite similar teeth on rear floor of mouth. Long spinous dorsal fin; anal fin 3-spined; interrupted lateral line. One species only, of unsolved percoid relationship but evidently not allied to Nandidae as once thought. Freshwaters; Burma to Indochina and Malaysia.

Family Pomacentridae (damselfishes and anemonefishes). Eocene to present. Abundant, conspicuous, active little fishes, often brightly coloured, found near shores and coral reefs, mainly in tropical but a few in subtropical seas. Resemble cichlids in general appearance and, like cichlids, have only 1 pair of nostrils. Lateral line continuous or interrupted; long spinous dorsal fin; anal fin with 2 spines, sometimes 3; soft dorsal and anal fins similar; caudal fin usually forked; all fins may have pointed filamentous ends; head with scales; scales large, ctenoid; bases of unpaired fins scaled; first ray of pelvic fin somewhat elongated; floor of mouth with 1 triangular, fused tooth plate in pharynx (pharyngeal plate). Territorial and pugnacious; about 250 species.

Family Percidae (perches, walleyes, darters). Eocene to present. Spinous and soft dorsal fins usually well separated; anal fin with 1 or 2 spines and short-based; scales ctenoid; bodies rather elongated. All freshwater, temperate species; perches and pike perches Holarctic with a few brackish-water species and a marine species of pike perch in parts of Black and Caspian seas; darters are native only to North America. Perches prefer quiet waters, darters running waters; pike perches occur in either and are semimigratory. Many species build nests and show parental care; size up to about 90 cm (3 ft) and 11 kg (25 lb) for walleyes; darters from 2.5 to 10 cm (1 to 4 in.). About 125 species, of which about 100 are darters.

Drawing by G. Christman

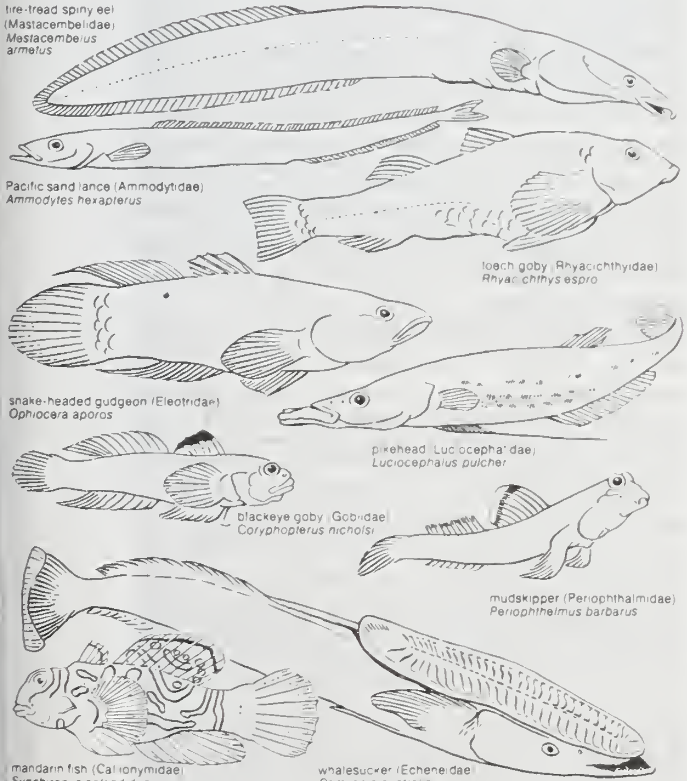

Figure 39: Representative perciforms of the families Luciocephalidae, Mastacembelidae, Echeneidae, Ammodytidae, Eleotridae, Gobiidae, Periophthalmidae, Rhyacichthyidae, and Callionymidae.

Family Sciaenidae (drums or croakers). Upper Cretaceous to present. Some species resemble cods, others resemble sea basses; most have lower jaw short or underslung, with upper jaw and snout extending beyond lower jaw; often 1 or more barbels (fleshy filaments) at tip of lower jaw. Spinous and soft dorsal fins separate; soft dorsal fin fairly long-based; anal fin small, with 2 spines (most percoids have 3 or more); lateral line continues out to posterior end of caudal fin (unusual for most percoids); air bladder often with intricate outpocketings and with muscles attached to it that operate to make resonating sounds in air bladder, hence name of drum; surface of head may be cavernous through expansion of lateral line canal system. Most species occur on slopes of continental shelf, a few around islands; most in tropics, a few in temperate waters; a few freshwater. About 160 species; size from about 100 gm to 100 kg (a few ounces to 220 lb); many are important food fishes.

Family Odacidae (rock whitings). Teeth incompletely fused together making a parrot-like beak as in parrotfishes (Scaridae), but odacids are evidently not related to wrasses (Labridae), parrotfishes, or whitings (Sillaginidae), all of which they also resemble. Seven species; southern Australian and New Zealand seas.

Family Labracoglossidae. Resemble grunts (Pomadasyidae), to which they are allied. Five species. Easter Island to New Zealand, Australia, Japan.

Family Sillaginidae (whitings). Oligocene to present. Elongated fishes with long, conical snout, small mouth; moderately long dorsal and anal fins; anal fin with 2 weak spines. About 6 species of small marine fishes of shallow water; Indo-Pacific, often in estuaries and river mouths; dig in bottom with long snouts for food.

Family Branchiostegidae (tilefishes). Pliocene to present. Body elongated; large, oblique mouth with strong canines; body deep through chest region; eyes high on head at top of steep sloping forehead; single, rather long dorsal fin; fin spines weak. Moderate to large body size; about 20 species, most in shallow seas of tropics and temperate zone.

Family Lactariidae (milk trevally). Miocene to present. Moderately deep-bodied, laterally compressed; mouth large, oblique; eyes large; pectorals pointed; 2 dorsal fins separated; anal fin long-based. One or 2 species marine in Indo-Pacific.

Families Owstoniidae and Cepolidae (bandfishes). Eocene to present. Owstoniids are marine, deep-water fishes, basslike, but large mouth is oblique, eyes large, and dorsal and anal fins long, continuous, and high; caudal fin with long rays; body tapers noticeably. Cepolids similar, but have a long tapering body and are shallow- and deep-water fishes. Cepolids occur from Europe through Mediterranean to India, China, Japan, and Philippines; owstoniids only in Far East; few species.

Family Mullidae (goatfishes). Miocene to present. Resemble minnows (Cyprinidae); have a long pair of chin barbels that usually lie flat against chin, except when in use as sense organs, probing the bottom for food. Spinous dorsal fin well separated from soft dorsal fin. Fifty to 60 species at reefs and shallow sandy or muddy bottoms near shore in tropics and warmer temperate seas.

Family Lutjanidae (snappers). Miocene to present. Resemble sea basses (Serranidae), but when mouth is closed jaw slips under bony cover over preorbital area (between eyes and jaw); enlarged canine teeth in jaws; spinous dorsal fin longer than soft fin and joined to it; anal fin short-based; caudal fin usually truncate. About 250 species; marine and brackish water in all warm seas.

Families Nemipteridae, Scolopsidae, Lethrinidae, Pentapodidae. Resemble Lutjanidae; some with wider preorbital area under which upper jaw slips; others (Nemipteridae) with molar teeth in sides of jaws and incisors or canine-like teeth at front end of jaws. About 50 species collectively; marine, Atlantic and Indo-Pacific, especially around coral reefs; some species up to 90 cm (3 ft) long; good food fishes.

Family Sparidae (breams, porgies). Eocene to present; resembling fishes of families Nemipteridae and Lutjanidae; mouth small but with a powerful dentition of incisors or canines across the front of the jaws and molar-like teeth to the sides, the teeth enlarging toward the rear of the mouth; used in crushing crustaceans, mollusks, and small fishes. About 100 species in shallow seas of tropical, subtropical, and temperate zones; most species less than 30 cm (1 ft) long, a few up to 120 cm (4 ft); important food and game fishes.

Family Gerreidae (mojarras). Small perchlike fishes with compressed, rather deep, silvery bodies; they are set off from most other percoids by their highly protrusible mouths used in probing soft, sandy bottoms to catch food organisms; about 40–50 species, mostly tropical marine, a few in freshwater; abundant in American tropics and East Indian region. Resemble fishes of family Leiognathidae, but the similarity is thought to be the result of parallel evolution.

Family Pempheridae (sweepers). Perchlike fishes with compressed body and a very short-based dorsal fin but long-based, low anal fin; big eyes. About 20 species in tropics of Atlantic, Indian, and Pacific oceans.

Family Bathyclupeidae. Resemble sweepers but apparently not related; compressed body; prominent lower jaw; single short-based dorsal fin; anal fin long-based; eyes large; mouth large. Few species; deep-sea midwaters, 400–500 m (1,300 to 1,640 ft) depth.

Family Carangidae (jacks, scads, and pompanos). Eocene to present. Lateral line usually strongly arched anteriorly and the posterior part usually armed with enlarged, keeled, scutelike bony scales; second dorsal and anal fins elevated and falcate anteriorly and sometimes followed by short-based free finlets; soft-rayed portions of dorsal and anal fins preceded by separated or nearly separated free, short spines; swift-looking fishes with streamlined bodies, very constricted caudal peduncle, deeply forked caudal fin, and long, sickle-shaped pectoral fins; eyes often covered with clear eyelids; worldwide in tropics and warm temperate areas; over 200 species; most are good food and game fishes.

Family Rachycentridae (cobias). Long and slender, somewhat resembling mackerels and shark suckers (remoras); may be related to shark suckers (family Echeneidae); soft portion of dorsal fin preceded by a row of short, separate dorsal spines. One species, worldwide in warm seas but absent in eastern Pacific; size up to 90 cm (3 ft) and over 70 kg (154 lb); pelagic in habit.

Family Coryphaenidae (dolphins). Sleek, fast-swimming fishes of tropic and temperate open seas; speeds up to 65 km (40 mi) per hour; dorsal and anal fins long-based and low; dorsal fin begins on head; deeply forked caudal fin; long, slender pelvic fins fitting into groove on belly; young males of one species change into adults with almost vertical forehead. Two species, 1 large, up to 150 cm (5 ft) and 25 kg (55 lb).

Family Formionidae (black pomfrets). Body deep, strongly compressed; dorsal and anal fins long-based and elevated at anterior end, both fins with spines rudimentary in adult fish; a few enlarged scutes at end of lateral line, a characteristic of fishes of jack family (Carangidae). One species, up to about 60 cm (2 ft); Indian Ocean to Australia and China.

Family Menidae (moonfishes). Eocene to present. Body strongly compressed, triangular, very deep behind head, with edge of chest razor-sharp; anal fin very long and low, reaching forward to pelvic fins; first ray of pelvic fin long and filamentous; mouth protrusible into an upward extended tube; 1 species, less than 30 cm (12 in.) long, in Indo-Pacific seas.

Family Leiognathidae (slipmouths). Oligocene to present. Small fishes; body greatly compressed, ovate; mouth small but highly protrusible into a tube pointing up or down; long dorsal and anal fins elevated anteriorly, folding down into scaly sheath lying alongside bases of the fins; exude large amounts of mucus after capture. About 25 species, mostly marine shallow-water shorefishes, some in estuaries; tropical Indo-Pacific area.

Family Bramidae (pomfrets). Body deep, strongly compressed; head broadly rounded in profile; pectorals long and curved; long-based dorsal and anal fins, low, sloping back to narrow caudal peduncle and deeply forked caudal fin; mouth small, oblique; about 23 species of darkly coloured fishes in rather deep waters of open ocean; size up to 90 cm (3 ft). One species, *Pteraclis velifera,* with enormously high and long fanlike dorsal and anal fins.

Family Caristiidae (manefishes). Rare black pomfret-like fish from midwater depth of 1,000 m (3,300 ft) over much deeper bottoms; dorsal fin begins far forward over end of cranium, high and like a mane; pelvic fins very long; 1 or 2 oceanic species.

Family Monodactylidae (fingerfishes). Includes family Psettidae. Small, silvery, ovate, small-mouthed fishes of salt and brackish water, temporarily in freshwater. Pelvic fins minute; dorsal and anal fins long; anterior spines of dorsal fin short and detached. Five species, coasts of Africa to India and Southeast Asia.

Family Toxotidae (archerfishes). Lower Tertiary to present. Moderately deep-bodied percoids distinguished by nearly straight line from dorsal fin to tip of jaws; jaws large, oblique; lower jaw prominent; jaws and roof of mouth adapted for expelling drops of water fired from the surface at insects on overhanging tropical vegetation in mangrove swamps. Dorsal and anal fins set far back on body; dorsal fin with 4 enlarged spines at front; 5 species, with black saddle markings or spots on dorsal surface; marine and freshwaters of tropical Indo-Pacific area.

Family Ephippidae (spadefishes and batfishes). Includes Chaetodipteridae, Drepanidae, and Platacidae. Eocene to present. Body deep, orbicular, greatly compressed laterally; long-based dorsal and anal fins, usually high, especially anteriorly in young; mouth quite small. About 15 species in tropics of world, few in temperate zone; size up to 40 cm (16 in.).

Family Pomacanthidae (angelfishes). Eocene to present. Body deep, laterally compressed; mouth quite small; strongly resemble Pomacentridae and Chaetodontidae (in which family they traditionally have been placed) but distinguished from these and other deep-bodied coral-reef fishes by a rather long, sharp spine projecting posteriorly from the lower part of cheek region (from the preopercle bone); profile of head from dorsal fin to tip of snout mainly convex, rarely straight, not concave as in butterflyfishes; young often differently coloured from adults; less than 100 species of conspicuous coral-reef and tropical fishes; mostly of small size, a few species up to about 45 cm (18 in.).

Family Scatophagidae (scats). Eocene to present; deep-bodied, laterally compressed; small mouth; 2 dorsal fins joined at base; bases of dorsal and anal fins scaled; about 4 species; coasts of Africa to Indo-Pacific, entering brackish and freshwater; scavengers, eating decaying plant and animal remains and fecal matter, including human; size up to 40 cm (16 in.).

Family Rhinoprenidae. One species, recently discovered, superficially similar to Scatophagidae, but really quite different. Long free filament at front of dorsal and anal fins and 1 on pectoral fin; posterior nostril of each side of head enlarged and confluent across snout. One species over muddy bottoms at river mouths in Gulf of Papua, Papua New Guinea.

Family Enoplosidae (old wife). Eocene to present. Body laterally compressed; spinous and soft dorsal fins elevated anteriorly, as is anal fin; general appearance gives impression in side view of two separate bodies joined together at midpoint; pelvic fins large. One species in rocky areas of Australian coast; size up to 22 cm (9 in.).

Family Chaetodontidae (butterflyfishes). Oligocene to present. Body deep, disk-shaped; mouth small, jaws sometimes on end of small (or, occasionally, fairly long) beak; slope of forehead from dorsal fin to tip of snout is concave, never convex; spinous portion of dorsal and anal fins usually prominent; bases of dorsal and anal fins scaled. Body often marked with oblique dark bands and one or two eye-like spots. Over 100 species in tropics of world, all marine; typical of coral reefs.

Family Pentacerotidae (pelagic armorheads). Resemble Chaetodontidae but with higher dorsal fin and much larger dorsal, anal, and pelvic spines; dorsal fin usually strongly elevated; head rough with exposed bony plates; snout usually elongated bearing small mouth at its end; lips with "hairy" skin. Seven or 8 species, in deeper coastal waters from South Africa, Australia, and New Zealand to Japan; size up to about 50 cm (20 in.).

Superfamily Kuhlioidea

Classified together under this superfamily are a number of percoid families that have in common the same pattern of main branches of a complex of taste nerves that occur on the body.

Family Kuhliidae (flagtails and aholeholes). Typical percoids resembling North American freshwater sunfishes and basses; dorsal fin single, notch between soft and spinous portions; dorsal and anal fins folding into scaly sheaths along their bases; 6 species of tropical Indo-Pacific oceans, preferring brackish water and freshwater; size up to 45 cm (18 in.); good food fishes.

Families Scorpididae (sweeps and halfmoons), *Kyphosidae* (sea chubs), *Girellidae* (opaleyes), *Coracinidae* (galjoen fishes). All similar families recognized by combination of ovate body, small mouth, strong caudal fin that is usually weakly forked; and, especially, a spinous dorsal fin with low spines followed by a higher evenly curved or falcate soft dorsal fin; about 36 species, many partly herbivorous; tropical and warm temperate coasts in Atlantic, Pacific, Indian oceans; size usually not over 45 cm; some are good food and game fishes.

Family Oplegnathidae. Pliocene to present. Strongly resemble Scorpidae and Kyphosidae, but incisiform teeth of young become fused in adult to form a parrot-like beak to upper and lower jaws; these fishes are not related to true parrotfishes (Scaridae); several species of shorefishes mostly in tropics of Southern Hemisphere; size up to 60 cm (24 in.).

Family Theraponidae (grunters or tigerfishes). Typical percoids of small bass type; colours dull or silvery or with horizontal dark stripes; dorsal fin notched, spinous part longer than soft part; some species make grunting sounds. Less than 25 species, Indian and western Pacific oceans and in fresh waters of Australia and New Guinea; small to medium size.

Family Arripidae (Australian salmon; ruffs). Not related to true salmons of Northern Hemisphere. Rather long, slender body; deeply forked tail; moderately long dorsal fin, a notch between the shorter spinous dorsal and longer soft dorsal fin. Two species; marine, young in brackish water; shallow waters off South Australia, New Zealand, and adjacent islands; size up to 1 m (3 ft); important food and game fishes.

Family Leptobramidae (salmon trout). A slender carangid-like species with large mouth, rather long-based anal fin, and a single dorsal fin placed behind the beginning of the anal fin; resembles Pempheridae but apparently is not related to it; a single species reaching 43 cm (17 in.) and about 2 kg (4 lb); off coasts of western Australia and New Guinea.

Family Emmelichthyidae (bonnetmouths). Includes families Caesionidae, Erythricthyidae, Dipterygonotidae, Maenidae, Spicaridae, Centracanthidae, Merolepidae by some authors. About 25 species of 2 general body types: one with slender, elongated bodies with moderately protrusible upper jaws; the other deeper bodied and with enormously protrusible upper jaws. Some school in open waters at depths of 3–45 m (10–150 ft), others in deeper water.

Family Pomatomidae (bluefish). Resembles Australian salmon (family Arripidae), but spinous dorsal smaller and separate from soft dorsal; anal fin longer; body more robust; 1 or 2 small spines before anal fin. One species, widely distributed in tropical and warm temperate seas; voracious feeder on other fishes; size up to 120 cm and 11 kg (4 ft and 25 lb); good game and food fish.

Family Nematistiidae (roosterfish or papagallo). Streamlined fish resembling jacks (Carangidae); dorsal fin remarkable for spinous portion consisting of greatly lengthened spines nearly separate from each other, the fin connected by fin membrane only at their bases, except the last ray, which is free at its base. Caudal fin deeply forked; pectoral fin long, falcate; mouth rather large. One species found only on west coast of Central America, from Gulf of California south to Panama; frequents sandy shores; size up to 35 kg (80 lb); game fish.

Superfamily Labroidea

Family Labridae (wrasses). Paleocene to present. Various body forms, but commonly cigar-shaped, fairly slender; snout moderately long, sometimes lengthened; dorsal and anal fins long-based and low; caudal fin truncate; especially characteristic are the noticeable lips and outcurving sizable canine teeth at ends of upper and lower jaws, the large scales and the habit of swimming around the coral reefs by "rowing" with the pectoral fins. About 300 species, many beautifully coloured and marked, often with differences of colour and pattern between sexes and between young and adults; size from 5 cm to nearly 2 m (2 in. to several ft), size up to 10 kg (22 lb); marine shallow-water fishes of tropics and warm temperate zone.

Family Scaridae (parrotfishes). Eocene to present; resemble Labridae but with stouter bodies and with teeth fused to form a parrotlike beak to upper and lower jaws; large scales in regular rows; herbivorous; about 80 species, often brilliantly coloured; species separable by colour and pattern; sexes often differ in colour. Size up to 120 cm (4 ft) and 20 kg (45 lb); tropical marine fishes.

Superfamily Gadopsoidea

Family Gadopsidae (river cod). Slender, somewhat elongated, with longer based dorsal and anal fins than typical percoid. Characterized by very slender and fairly long pelvic fins located in front of pectoral fins; caudal fin rounded. One species, rivers of southern half of Australia; somewhat resembles Ophidiidae (order Paracanthopterygii) but apparently is a derivative of family Serranidae; size up to 60 cm (2 ft).

Superfamily Cirrhitoidea

Family Cirrhitidae (hawkfishes). Small colourful perchlike fishes having lower rays of pectoral fins unbranched, thick-ended, and separate from one another; small flag of skin projects from tip of each spine of dorsal fin; about 35 species; shallow coastal waters in warm seas.

Families Chironemidae, Haplodactylidae, Cheilodactylidae, and Latridae. Similar to Cirrhitidae; 25 to 30 marine species, mostly in shallow waters of Australia and New Zealand, some species off South America; size up to 60 cm (2 ft).

Superfamily Champsodontoidea

Family Champsodontidae. Small, elongated spiny-rayed fishes with a small spinous first dorsal fin and rather long, soft dorsal and anal fins; pelvic fins rather large; eyes near top of head and close together; unusually large mouth, the jaw extending obliquely past the eyes; several species; carnivorous; deep waters of Indo-Pacific oceans.

Superfamily Trichodontoidea

Family Trichodontidae (sandfishes). Resemble codfishes, but eyes high on side of head; mouth large, oblique; lips fringed; pectoral fins with long base extending forward past pelvic fins. Two species; marine; North Pacific; to 25 cm (10 in.).

Superfamily Trachinoidea

Family Opistognathidae (jawfishes). Resemble Clinidae, but jaws large to huge, extending far past eye; dorsal fin long-based; spinous and soft portions continuous; anal fin long-based; body usually elongated, slender; eyes almost at anterior tip of head; pelvic fins below pectorals. About 24 species, mostly small, in shallow tropical and temperate seas.

Family Bathymasteridae (ronquils). Resemble Opistognathidae, but jaws not so large; no spines in dorsal or anal fins; pelvic fins slightly ahead of pectorals; about 8 species; bottom-dwelling; coasts of North Pacific Ocean.

Family Mugiloididae. Includes Parapercidae and Pinguipedidae. Some resemble labrids in long dorsal and anal fins (sometimes with few spines), enlarged lips that appear to curl back, and enlarged canines at front of jaws. Body elongated, cylindrical; usually spotted and banded; eyes near top of head. Size from small up to 60–90 cm (2–3 ft); about 30 species; marine; bottom dwellers, coasts of South America, South Africa, Indo-Pacific to Japan; a few good food species.

Family Percophiidae. Includes Bembropidae and Hemerocoetidae, resemble flathcads (Platycephalidae); body long, slender; head flattened; eyes on top of head, close together; separate spinous and soft dorsal fins; dorsal and anal fins long-based; jaws large. About 12 species; marine, from shallow down to about 200 m; South America, Indo-Pacific to Japan.

Family Cheimarrichthyidae (torrent fish). Small, resembling a cottid or sculpin (family Cottidae); eyes on top of head and close together; 1 species; freshwater streams of New Zealand; young in brackish water.

Family Trachinidae (weever fishes). Eocene to present. Body elongated, compressed, deep at head end, tapering to narrow, small caudal fin; a separate short-based spinous dorsal fin with black membrane and poison glands along grooves in each spine; anal and soft dorsal fins long-based; a long spine on gill cover with poison glands along grooves of spine; eyes black in upper half, white in lower half; scales small, set in distinct oblique rows; 4 species, marine shallow water down to 90 m (300 ft); lie buried in sand with eyes and top of head showing; northern Europe, Mediterranean, Pacific coast of South America; venom very painful, even dangerous.

Family Trichonotidae (hairfins). Resemble Percophiidae and Mugiloididae, but body extremely elongated and dorsal fin unusually high; snout pointed; lips fringed, dive headfirst into sand. Several species; tropical and subtropical Indo-Pacific oceans.

Family Creediidae. Elongated little fishes resembling Percophiidae; 2 species known; coasts of Australia, Marshall and Mariana islands.

Family Limnichthyidae. Resemble Percophiidae; 5 species; New Zealand, Australia, and Society, Marshall, Mariana, and Hawaiian islands; sand burrowers.

Family Oxudercidae. A single species from coast of Asia at Macau; relationships still in doubt.

Superfamily Uranoscopoidea

Eocene to present. Three families; resembling toadfishes (Batrachoididae) and weever fishes (Trachinidae). Bodies rather elongated, with long dorsal and anal fins usually with few or no spinous rays; head broad, deep, flattish on top; eyes on top of head and somewhat erectile; mouth broad, oblique; lips fringed with toothlike dermal projections that interdigitate and strain water through sand when the fishes are buried to top of head and eyes; similar fringe of skin at upper end of gill slit; pectoral fins enlarged and fanlike; pelvic fins anterior to pectorals.

Family Leptoscopidae. Sand-burrowing fishes; no spines in dorsal and anal fins. Three species; marine; coasts of Australia and New Zealand; size up to 30 cm (12 in.).

Family Dactyloscopidae (sand stargazers). General features as described under superfamily; body elongated. Shape of pelvic fins is characteristic: each has 3 thickened segmented rays whose tips are free from the fin membrane, divergent and somewhat curled. Small fishes, mostly marine, up to about 10 cm (4 in.); burrow in sand with eyes and mouth protruding from surface of sandy bottom; 20 to 25 species in tropical America in Atlantic and Pacific oceans.

Family Uranoscopidae (stargazers). Head extremely broad and deep; posterior half of body tapering to a small truncate tail fin; eyes located on top of head, projecting above surface of head; large posteriorly pointing spine on shoulder girdle above pectoral fin (found in some species); dorsal fin moderately long and either with a short, nearly separate spinous portion or spines absent; anal fin moderately long and with few or no spines; large electric organs located behind eyes of species of genus *Astroscopus;* the only marine teleosts with electric organs; about 25 species live buried on sandy bottoms usually in shallow shore areas; a few species are found at greater depths, to about 600 m (2,000 ft), Atlantic, Pacific, and Indian oceans; size up to about 9 kg (20 lb).

Superfamily Chiasmodontoidea

Family Chiasmodontidae (swallowers). Slender fishes with extremely deeply cleft mouth; large, backward-pointing teeth; dorsal fin long with spinous and soft dorsals separate; pelvic fins thoracic. Capable of swallowing and holding in their greatly distensible bellies fishes larger than themselves. About 12 species in open oceanic waters down to 500 m (1,600 ft); size up to 15 cm (6 in.); relationships in doubt.

Superfamily Notothenioidea

Four families of codlike or sculpinlike percoids found mainly in the Antarctic, some in cold temperate Southern Hemisphere seas near Chile, Argentina, and New Zealand; superfamily includes about 75 percent of all Antarctic fishes.

Family Bovichthyidae. About 15 species in subantarctic and south temperate seas, off Chile, Argentina, southern New Zealand, and southern Australia; 1 species in rivers of South Australia and Tasmania.

Family Nototheniidae (Antarctic cods). Miocene to present; about 50 species, most in subantarctic waters; some species near Antarctic continent; a few in cold temperate zone, 1 species in rivers of southern South America. Mainly bottom dwellers of littoral zone, some deep-water species resemble true cods (Cottidae) and have a barbel on lower jaw; 2 species, large, up to 150 cm (5 ft).

Family Bathydraconidae (Antarctic dragonfishes). About 15 species; true Antarctic fishes, occurring on coasts of Antarctic continent; body greatly elongated; usually a spatulate, pikelike snout; no first dorsal fin; live on coasts of Antarctic continent to depths of 500–700 m, a few down to 2,500 m. Size up to about 50 cm, but usually much smaller.

Family Channichthyidae or Chaenichthyidae (white-blooded fishes or icefishes). Famous white-blooded fishes of the Antarctic; lack red blood cells and hemoglobin. Mostly large, up to 60 cm (2 ft) long, with scaleless body and 2 or 3 lateral lines each side; head large, snout long, spatulate, pikelike; teeth large; jaws nonprotractile. About 16 species, all in Antarctic except 1 in subantarctic; mainly bottom dwellers feeding on crustaceans and small fish; most at 100 to 200 m (330–660 ft), some to 700 m (2,300 ft).

Suborder Stromateoidei

Five percoidlike families with an unusual and characteristic feature, a toothed saccular outgrowth in the gullet directly behind the last gill arch. One family, the Amarsipidae, lacks the toothed saccular outgrowth in the gullet. Stromateoids may be related to fishes of the superfamily Kuhlioidea.

Families Stromateidae (butterfishes), *Centrolophidae* (medusafishes), *Nomeidae* (flotsamfishes), *Ariommidae, and Tetragonuridae* (squaretails). Eocene to present; slender to ovate, deep-bodied fishes; dorsal fin continuous or spinous portion set off from soft portion by deep notch; in the most generalized species, which resemble Kyphosidae, the soft dorsal is preceded by about 6 low, stoutish spines; other species resemble Carangidae. Eyes often with adipose (fatty) tissue around them; pelvic fins absent in some species, especially in ovate species; skeleton often weakly calcified; scaly sheath along bases of dorsal and anal fins. Young often found under jellyfishes or flotsam; adults live in deeper layers of ocean over continental shelves or are pelagic; a few species close to shore, in bays, even entering estuaries; 78 recognized species, many rarely seen; some feed largely on jellyfishes; others on crustaceans, tunicates, and small fishes; many are important commercially, especially in the Orient; family includes good-tasting species such as butterfishes and pompanos. Tropics to temperate zone; never near oceanic islands; size 10–120 cm.

Suborder Icosteoidei

Family Icosteidae (ragfish). A single species of rare deep-sea fish of North Pacific Ocean; body highly flexible in water, limp as a rag out of water; little is known of its anatomy. Resembles Stromateidae; presumably derived from a percoidlike ancestor; no spines in fins; pelvics and scales present in young, both absent in adult; body elongated, much compressed; up to 220 cm (7 ft).

Suborder Blennioidei

Fairly large suborder composed of 2 groups, the tropical blennies, some of which are percoidlike, and the northern blennies. The northern blennies are eel-like fishes, but the appearance of their faces and the aspects of their fins generally resemble those in the tropical blennies.

Superfamily Blennioidea (tropical blennies)

All soft, articulated fin rays in the dorsal, anal, and pelvic fins are unbranched; pelvic fins, which are seldom greatly reduced, consist of 1 spine and 4 or fewer rays and are located in front of the pectoral fins; there are the usual 2 nostrils on each side of the head. Exact 1-to-1 ratio between the vertebrae and the dorsal rays and posterior anal rays; only 1 lateral line. About 620 species.

Family Clinidae (clinids). Eocene to present. Percoidlike fishes, some moderately elongated, rather flat-sided, usually with somewhat pointed snouts and fleshy lips; dorsal and anal fins rather high and long-based, with fin membranes conspicuously supported by thin, riblike fin rays; caudal fin fanlike, not large; pelvic fins ahead of pectorals, slender; 1 spine and usually 2 or 3 rays; pelvics in some species appear usable in walking movements; cirri (bushy tentacles of skin) often present above eyes, on anterior nostrils, and just behind head on each side. Body scaled; scales cycloid; first 3 rays of dorsal fin often higher and more or less separate from rest of dorsal. A few species "four-eyed" (*i.e.,* with eye divided so as to see out of water). Most inhabit tide pools, kelp, rock crevices; some species down to 30 m (100 ft); size up to 30 cm (12 in.), but most are smaller; about 180 species.

Family Tripterygiidae (threefin blennies). Pliocene to present. Much like clinids but dorsal fin divided into 3 distinct parts, the first 2 of spines only; small bottom fishes of reef and rocks. About 100 species mostly in warm seas.

Family Blenniidae (combtooth blennies). Eocene to present. Resemble clinids in fins and body shape but differ in being scaleless, in having a steep forehead and only a single row of teeth in both jaws, the teeth being close-set, long, comblike. Sometimes a pair of large to enormous curved "canines" farther back in jaws; some species hop about out of water in intertidal zone; fins without pungent spines; eyes large and at top of forehead; pelvic fins with 2 rays. About 300 species, in tropical, subtropical, and warm temperate seas; small size.

Family Chaenopsidae (pike blennies). Pliocene to present. Body very elongated; jaws long; long gill area; dorsal and anal fins long, confluent with caudal fin; no scales or lateral line; 6 species in tropical and subtropical marine shore areas of Central America and Caribbean; small fishes living in worm tubes and burrows.

Family Pholidichthyidae (engineer fish). Very elongated eel-like fish; reclusive, living under excavations; move sand and gravel in mouths; known previously only by young stage; adult recently discovered by L. Dempster. One species; marine; in tropics, Indonesia and Philippines; size up to 30 cm (12 in.); poorly known; relationships in doubt.

Family Notograptidae. Eel-shaped; dorsal and anal fins long-based and high, both confluent with caudal fin; pelvics 1-rayed, filamentous, placed before pectorals; body scaled, mouth large. Two small species; marine; western Australia.

Superfamily Stichaeoidea (northern blennies)

Eel-like fishes; single pair of nostrils; dorsal and anal fins long-based and often joined to caudal fin; pelvic fins placed a little before pectoral fins, consisting of 1 spine and fewer than 4 rays; bottom-dwelling fishes usually of littoral zone, some supralittoral; a few in deep water (down to 450 m).

Family Stichaeidae (pricklebacks). Includes families Chirolophidae, Lumpenidae, Xiphiodontidae, Cebidichthyidae. Eel-like; body usually scaled; dorsal fin with spines only or some soft rays at rear of fin; pectorals reduced; pelvics present or absent; some species with 3 or 4 lateral lines but most species lacking lateral line. About 54 species, most in North Pacific, some in Atlantic; often among seaweeds when tide is out; also in deeper water (to 200 m); most feed on invertebrates, a few on seaweed; most species small, a few up to 60 cm.

Family Pholidae (gunnels). Elongated; strongly compressed laterally; scaled; pelvics reduced to 1 spine and 1 ray, very small or absent; spines only in dorsal fin. About 8 species, most in North Pacific; also in North Atlantic; size small; intertidal zone or shallow water; feed on small bottom invertebrates.

Family Anarhichadidae (wolffishes). Big head and long tapering body, laterally compressed; massive dentition on jaws, roof of mouth, and throat for crushing mollusks, sea urchins, crustaceans; length to 2.3 m (7.5 ft). Nine species, in northern oceans; littoral zone to 300 m (1,000 ft); good food fishes.

Family Ptilichthyidae (quillfish). Extremely elongated, body ending in a free, fleshy point; pelvic fins absent; dorsal and anal fins like vanes of a feather. One species, rare; North Pacific.

Family Congrogadidae. Includes Haliophidae. Resembles Stichaeidae but mouth and lips large; fins almost or entirely spineless; 3 lateral lines. About 8 species; rock-dwelling, in shallow coastal waters of Indo-Pacific from Africa to Japan.

Family Zaproridae (prowfish). A single species like a shorter, deeper bodied prickleback; pelvic fins absent; size up to 2.8 m (9 ft); deeper coastal waters to 350 m, California to Alaska.

Family Scytalinidae (graveldiver). Eel-like, with dorsal and anal fins soft-rayed and not beginning until middle of long straight body; body appears to flare out somewhat at these fins; pelvic fins lacking. One species; marine, California to Alaska; small, to 15 cm (6 in.); burrows quickly in sand or gravel in intertidal zone.

Suborder Acanthuroidei

Modified percoid-like fishes characterized by peculiarities of bones suspending the jaws, which thereby are extended far forward as small nibbling mouths at end of more or less lengthened snout.

Family Acanthuridae (surgeonfishes). Includes Zanclidae. Percoid-like fishes characterized by usually 1 or 2 lancet-like spines (like a surgeon's scalpel) alongside the caudal peduncle (in front of base caudal fin); body deep, compressed; dorsal and anal fins long-based; scales small; eyes high on side of head; mouth small, low, sometimes extended into a beak; teeth close-set and lobate. About 75 species; many herbivorous; inhabit shallow tropical shores, a few in deeper water.

Family Siganidae (rabbitfishes). Resembling surgeonfishes but uniquely characterized by pelvic fins each having 2 stout spines, located along the outer and inner edges, respectively; both spines are grooved for carrying venom; no lancet-like spine or buckler on caudal peduncle; mouth small and rabbitlike, used for nibbling algae. About 18 marine species of small to moderate size; tropical Indo-Pacific, around coral reefs and rocky areas.

Suborder Scombroidei

Streamlined, mackerel-like or marlin-like fishes the interrelationships of which are in doubt; upper jaw not protrusible; maxillary bones of upper jaw more or less firmly attached to non-protractile premaxillaries that lie ahead of them.

Family Gempylidae (snake mackerels). Eocene to present. Elongated, laterally compressed; mouth large, with large, cutting teeth; spinous part of dorsal fin longer than soft-rayed part, the latter often broken up into finlets posteriorly; pelvic fins usually not rudimentary. Sixteen species; tropical and temperate seas; down to 600 m (2,000 ft); length to 1 m (40 in.); some commercial value; good food fishes.

Family Trichiuridae (cutlass fishes). Paleocene to present. Elongated, bandlike body; large mouth with large fangs anteriorly. Scaleless; dorsal fin long, spinous anteriorly, anal fin long-based, spines short; caudal fin deeply forked on most species, absent in some (body ending in tapered point); pelvic fins reduced to scalelike spine and 1 small ray, or absent. Fifteen species in warm oceans; rather deep water offshore, to about 1,000 m (3,300 ft); piscivorous.

Family Scombridae (tunas and mackerels). Moderate to large, streamlined, swift-swimming, schooling fishes; body often thickly rounded, tapering to a narrow caudal peduncle bearing in some species 2 or 3 keels on its side; caudal fin widely forked or lunate (scimitar-shaped); distinguished from all fishes by series of separate finlets following spinous first dorsal and spinous anal fins; well-developed vascular system under skin of tunas is associated with sustained high-speed swimming and a body temperature a few degrees higher than that of the surrounding water; make extensive migrations to spawning and feeding grounds; fins fit into grooves or depressions on body; about 40 species, open waters of tropics and warm seas of world; feed on fish, crustaceans, squids, and other abundant animal life; length 30 cm to 3.3 m, weight to 800 kg. Many species subjected to ever-increasing fishing exploitation and will be threatened with extinction.

Family Xiphiidae (swordfish). Bones of upper jaw prolonged into a swordlike structure, flatter and sharp-edged, as compared with the round, shorter bill of marlins and billfishes; dorsal fin high and short-based, not extending beyond middle of body; caudal fin with high lobes; second dorsal fin small; pelvic fins absent; no teeth in jaws except in very young; no scales. Probably only 1 species, *Xiphias gladius*, worldwide in tropics and temperate seas; from surface to 400 m; size up to 3.6 m (141 in.) and 450 kg. (985 lb.). Sword is lashed about inside schools of fishes; injured fishes are eaten. A major big-game fish; excellent eating and commercially important.

Family Istiophoridae (billfishes, marlins, sailfishes, and spearfishes). Bill round and shorter compared with sword of swordfish; dorsal fin long, extending almost the length of back of body and reaching striking height in the sailfish, *Istiophorus gladius;* pelvic fins present as thin filaments; body scaled; 2 small keels on each side of caudal peduncle; fine teeth on jaws. About 7 species; worldwide in warm seas; all are large species, the black marlin (*Makaira indica*), the largest, probably attains 900 kg (2,000 lb); record for rod and reel is 710 kg (1,560 lb); greatest game fishes in the ocean, and excellent food fishes, of considerable economic importance.

Family Luvaridae (louvar). One species; rare; resembles a dolphin (family Coryphaenidae) in its very high forehead and eye placed low almost on level with mouth; mouth small, toothless; body deep, laterally compressed; a fleshy keel on each side of caudal peduncle; pelagic in tropics and subtropics; length to 1.5 m (5 ft).

Suborder Anabantoidei

Small percoid-like fishes characterized by an accessory air-breathing chamber of labyrinthic structure on each side of head, above regular gill chamber; an unusual patch of teeth on roof of mouth, teeth which attach to floor of cranium; usually build foam nests. Freshwater fishes of Southeast Asia, India, and Africa; about 70 species in 5 families, 4 of which are closely related; the fifth, Badidae, is more generalized.

Family Badidae. Resembling Anabantidae externally but lacking accessory air-breathing chamber. Have special patch of teeth on roof of mouth and characteristic courtship behaviour of anabantids; 1 species, freshwaters of India and Southeast Asia; small, 5–8 cm (2–3 in.) long.

Family Anabantidae. Pleistocene to present; about 20 species, freshwaters of tropical Africa, Southeast Asia and Philippines; includes the "climbing perch"; size small.

Family Belontiidae (fighting fishes, some gouramis, and others). About 50 species of small freshwater fishes from tropical Africa, India, Burma, Sri Lanka, Southeast Asia, Malaya; includes Siamese fighting fish (*Betta splendens*), various species of gouramis, which have 1 ray of each pelvic fin extended into an elongated filament; paradise fishes and other popular aquarium fishes. Most of these species were formerly placed in family Anabantidae.

Family Helostomatidae (kissing gourami). Freshwater, Southeast Asia; popular aquarium fish; one species.

Family Osphronemidae (gourami). Pelvic fins each with 1 ray drawn out into a long filament; 1 species; freshwater in Sumatra, Java, Borneo, grows to about 9 kg (20 lb).

Suborder Luciocephaloidei

Family Luciocephalidae (pikehead). Pike-like in body form and long head, an accessory suprabranchial air-breathing chamber (but not labyrinthic); bony plate in throat region; peculiar jaws. One species, freshwater; Malay Archipelago and Peninsula.

Suborder Mastacembeloidei

Family Mastacembelidae (spiny eels). Eel-like; head elongated with fleshy, mobile proboscis projecting beyond lower jaw; soft dorsal fin preceded by series of erectile spines. About 50 species, freshwaters from tropical Africa to Southeast Asia up to China; up to 90 cm (3 ft), but most much smaller; some attractively coloured aquarium fishes.

Family Chaudhuriidae. One species in freshwaters of Burma; similar to spiny eels but small and without fleshy proboscis.

Suborder Kurtoidei

Family Kurtidae (nurseryfishes). Peculiar, small, percoid-like; males carry eggs, stuck under an anteriorly pointing hornlike process on top of back of head. Two species; brackish water and lower parts of streams; Indo-Malaysia and New Guinea.

Suborder Echeneioidei

Family Echeneidae (remoras). Oligocene to present; differ from percoids mainly in having a sucking disk on top of head, modified from the spinous first dorsal fin. About 10 species; warm marine seas; ride attached to large fish or other marine animals or ships; carnivorous; some are cleaner fish for other fishes; length 30 to 90 cm (1 to 3 ft).

Suborder Ammodytoidei

Families Ammodytidae and Hypoptychidae (sand lances). Eocene to present. Long slender percoid-like fishes with long, pointed head and projecting lower jaw; dorsal fin long-based, with soft rays only; pelvic fins thoracic or (usually) absent. About 18 species; most seas of the world, especially colder waters; sand burrowers; large schools near shores form an important food source for many other fishes; 20–40 cm (8–16 in.).

Suborder Gobioidei

Almost all with pelvic fins located beneath pectorals and joined together to form a vacuum cup or suction disk; some with pelvic fins close together but not in form of a suction cup; a few lack pelvics; all lack one particular bone of cranial roof. More than 800 species, most of small size, living as bottom dwellers, worldwide, in saltwater, freshwater, or brackish water, especially in tropics.

Family Eleotridae (sleepers). Pelvic fins close together or in contact anteriorly, but not united into a sucking cup; short-based spinous first dorsal fin and longer based soft-rayed second dorsal; all fins usually with rather long fin rays; no lateral line. Numerous species; found along coasts and rivers in tropics and subtropics; most 10–30 cm (4–12 in.) long, one to 90 cm (35 in.) in length.

Family Gobiidae (gobies). Eocene to present. Pelvic fins united to form a suction cup; no lateral line; simple-looking but often colourful fishes with 2 dorsal fins; all fins rather conspicuously large compared with small, usually slender body; definite rows of naked lateral-line organs on head. More than 700 species; size from 1.2 cm (0.5 in., world's smallest vertebrates) to something under 30 cm (12 in.), with most less than 10 cm. Shallow coastal waters of tropics and temperate zones; usually resting on bottom or hidden; carnivorous.

Family Periophthalmidae (mud skippers). Elongated gobies with blunt head; eyes erectile, prominent, on top of head; pectoral fins with muscular base used to walk over mud and climb mangrove roots; about 6 species in estuaries and mud flats of Indian and Pacific oceans, to Japan.

Family Rhyacichthyidae (loach goby). Pelvic fins widely separated; head flattish, pointed; mouth ventral; 1 species living in torrential mountain streams of Indonesian Archipelago, up to Philippines; size up to 33 cm (13 in.).

Family Gobioididae. Elongated, eel-like gobies; dorsal fin very long, spinous part distinct from, but connected to, soft part; dorsal and anal fins confluent with caudal; eyes tiny to indistinct; mouth often obliquely upward; about 20 species, marine and brackish water of tropical America, Indian and Pacific oceans; about 8–30 cm (3–12 in.).

Family Trypauchenidae. Eel-like; scaled; dorsal and anal fins very long and confluent with caudal; pelvic fins united at base but not forming a cup or disk; eyes tiny. A blind cavity above gill cover opening to exterior by a pit. Burrowers in mud and gravel; about 12 species, along coasts and estuaries from Africa to Japan and Oceania.

Family Kraemeriidae. Rare little elongated fishes; pelvic fins separate; chin of lower jaw large, pointed, forming terminal end of head; eyes small, on top of head; 2 species, Indo-Pacific oceans.

Family Microdesmidae. Rare, small, eel-like; chin large, forming pointed end of snout; about 6 species; both coasts of tropical America, West Africa, tropical Pacific.

Suborder Callionymoidei

Family Callionymidae (dragonets). Eocene to present; resembling flatheads (Platycephalidae); body flattened, broad, muscular; snout very short; mouth small; gill openings restricted, located on top of head; eyes on top of head and close together; pelvics in front of pectorals; large spine pointing posteriorly at angle of preopercle on gill cover; bottom dwellers from tidepools down to 600 m (2,000 ft); burrow into sand; push along bottom using pelvic fins; about 40 species found in tropical and temperate zones.

Family Draconettidae. Look like callionymids but are separated on differences in head skeleton; no preopercular spine; a few species; North Atlantic and North Pacific in deep water.

Critical appraisal. Classification of perciform fishes will be receiving much more study in the future. Expected changes include removal of some groups from the order, addition of some from other orders, and considerable realignment of many groups within the Perciformes. Evidence suggests removal of Gobioidei to a preperciform position, possibly as a distinct order. The snake-heads (order Channiformes) should likely be returned to the order Perciformes, associated with the anabantoid and luciocephaloid fishes. Particularly difficult problems are the relationships and classifications of trachinoid, uranoscopoid, notothenioid, and stichaeoid fishes. Studies are presently being made on possible interrelationships between clusters within the 60 or more families of percoid fishes (suborder Percoidei). The placement and relationships of the atherinoid (sometimes called percesocine) fishes are still in dispute. The present classification follows that of Greenwood *et al.* in the removal of Atherinidae from perciform fishes and in the removal of the ophidioid and zoarcid fishes. Support for retaining the Atherinidae in order Perciformes and for other differences in the order Perciformes has been given by an American ichthyologist, W.A. Gosline, in a series of papers published between 1962 and 1971. Questions of relationships between carangid, rachycentrid, echeneid, and scombroid fishes are still unsettled. Many large and exciting problems thus remain. (W.C.F.)

Flatfishes—flounders, soles (Pleuronectiformes)

Members of the fish order Pleuronectiformes—which are commonly called flatfishes, flounders, or soles—are unique among fishes in being asymmetrical. Pleuronectiformes are strongly compressed, with both eyes on one side; other fishes and vertebrates in general are bilaterally symmetrical. The asymmetry is believed to have evolved from a generalized, symmetrical percoid (sea bass) body pattern in a fish that habitually rested on its side. Larval flatfishes have an eye on each side of the head, but during a period of rapid body change (metamorphosis) one eye migrates to the other side of the head, after which the larvae settle to the bottom. Osteological changes resulting from the eye migration are responsible for the asymmetry in the flatfish skull.

GENERAL FEATURES

Flatfishes of the family Pleuronectidae are commercially important in northern waters, and members of other families are taken in limited quantities. Some Bothidae and Soleidae (soles) are exploited in tropical and temperate waters, but no other flatfishes are utilized to the extent that Pleuronectidae are.

Flatfishes are primarily found in temperate and tropical seas, with some species extending northward into the Arctic. Sizes range from about 100 millimetres (four inches) to the large Atlantic halibut, which attains a length of more than two metres (nearly seven feet) and a weight of about 325 kilograms (716 pounds). Most species are marine, but some spend all or part of their life in freshwater. Flatfishes are found in depths up to 1,000 metres (3,300 feet), but most occur on the continental shelf in less than 200 metres of water.

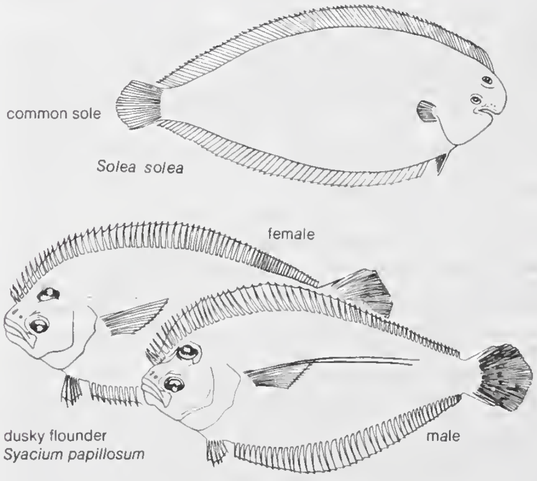

Figure 40: Body plan and sexual dimorphism in the flounder.

NATURAL HISTORY

Reproduction. Flatfishes generally spawn offshore, but some spawn in estuaries. Fecundity is high, females generally releasing at least several hundred thousand eggs (large female halibut have between 2,500,000 and 3,000,000 eggs). The eggs are small and float freely (pelagic) or sink to the botton (demersal), with or without oil globules. Newly hatched larvae are 1.5 to three millimetres long (approximately $^1/_{16}$ to $^1/_8$ inch). Active feeding begins shortly after hatching, and mortality of newly hatched larvae is extremely high. Larvae drift with currents (planktonic) until metamorphosis, or shortly afterward, and then settle to the bottom to assume their adult bottom-living (benthic) existence. Swimming is accomplished by undulating movements of body and fins, rather than by sculling with the caudal fin as in most other fish.

Feeding behaviour. Flatfishes lie on the bottom, generally covered by sand or mud, with only their eyes protruding. The eyes can be raised or lowered and moved independently. Flounders feed primarily on crustaceans, other bottom invertebrates, and small fish. When feeding they remain motionless until their prey ventures too close and then literally leap off the bottom in pursuit. Flatfishes in turn fall prey to a variety of large fish and cetaceans (whales, porpoises, etc.), but the primary predator of flatfishes is man.

FORM AND FUNCTION

Many species display sexual dimorphism, with the male having one or several of the following characteristics: elongated pectoral-fin rays, wider interorbital bones, spines on the head, tentacles on the eyes, more elaborate pigmentation. Flounders have a long dorsal fin extending from the head to caudal (tail) fin and an anal fin extending from vent (anus) to caudal fin in most species. Pectoral fins are present on all larval flatfishes but are lost or reduced in adults of the families Soleidae and Cynoglossidae. Caudal-fin rays and their supporting structures are variable. Scales are ctenoid (rough edged) or cycloid (smooth). Dentition is variable and corresponds to feeding habits of the species. Active predators have large, well-developed teeth in both jaws, whereas those living primarily in mud and feeding on bottom invertebrates have teeth only on the lower jaw of the blind side. Sexes are easily distinguished because the ovaries extend posteriorly from the body cavity beneath the skin and a thin layer of muscle immediately above the muscles of the anal-fin rays. Testes cannot be seen without dissection. The stomach and intestines curl within the body cavity to form a loop.

Migration of the eye during metamorphosis

The main feature of metamorphosis is the migration of the eye around or through the head. This is accomplished as a movement either over the middorsal ridge or through the head, in a depression between the supraorbital bars (over the eye) and ventral edge of the dorsal fin. The supraorbital bars extend forward from the cranium to the ethmoid region of the skull (the area in front of the eye), gradually shifting ventrally and coming to lie next to one another. As the eye migration begins, the dorsal edge of the supraorbital bar is reabsorbed to make room for the eye moving through the head. The supraorbital bars ossify and become the interorbital bone after the eye has completed its migration. The blind- (bottom-) side frontal bone shifts to the ocular (upper) side and forms a portion of the optic-capsule floor for the upper eye. Torsion (twisting) of the frontals, ethmoid, and mouthparts is the essential feature of the flatfish skull.

Normal pigmentation on adult flatfishes consists of a coloured ocular side and an unpigmented (white) blind side. The ocular side is variable in pigment pattern and intensity. Flatfishes can mimic their background by assuming a similar coloration. Partial or complete albinism is known in some species, but a more common colour variation is ambicoloration (coloration on both sides). Ambicoloration can be partial or complete and is often associated with incomplete migration of the eye (in which the migrating eye stops on middorsal ridge) and a hooked appearance, caused by the unattached origin of the dorsal fin. Reversal (eyes and pigmentation on the side that normally is unpigmented) is fairly frequent in some species but quite rare in others.

CLASSIFICATION

Flatfishes are divisible into three suborders and seven families.

ORDER PLEURONECTIFORMES
(Heterosomata of some authors)
Allied to Perciformes but asymmetrical, compressed, both eyes on one side of head; pelvic bones attached directly to cleithrum. Swim bladder absent in adults. Fossil records for this group of fish are limited, extending from Paleocene to Recent, about 65,000,000 years.

Suborder Psettodoidei
The least specialized (most primitive) flatfish. Spines present in dorsal, anal, and pelvic fins; dorsal fin not extending onto head; eyes on either right (dextral) or left (sinistral) side; maxillary (upper-jaw) bone with well-developed supplemental bone; vertebrae 24–25 (10 precaudal, 14–15 caudal).

Family Psettodidae (primitive flatfishes)
Same characters as given for the suborder. Two species, one from Indo-Pacific and one from Africa; attain a length of about 0.6 m (2 ft).

Suborder Pleuronectoidei
No spines in fins (one spine in pelvic fin of Citharidae); dorsal fin extending forward onto head; usually no supplemental bone on maxillary (may be present or absent in Citharidae); vertebrae 27–70 (generally numbering 34 or more); preopercular margin free; lower jaw prominent; nostrils asymmetrical (that on blind side being near edge of head).

Family Citharidae
Eyes either dextral or sinistral; anus on ocular side; gill membranes widely separated; dorsal- and anal-fin rays not shortened posteriorly. Five monotypic genera found in the Indo-Pacific and Mediterranean and off Africa and Japan; attain a length to about 30 cm (about 1 ft).

Family Scophthalmidae
Eyes sinistral; anus on blind side; gill membrane widely separated; dorsal- and anal-fin rays shortened posteriorly; pelvic-fin bases long (both extending forward onto the urohyal). Four genera and 10 species found in North Atlatic and Mediterranean Sea; attain lengths to about 1 m (3 ft 3 in.) and weights to about 23 kg (approximately 50 lb).

Family Bothidae (left-eyed flounders)
Eyes sinistral; anus generally far up on blind side; gill membranes connected; dorsal- and anal-fin rays shortened posteriorly; pelvic-fin bases on ocular side short, on blind side may be short or long, 6-fin rays in all but 1 species. Thirty genera with about 200 species, found primarily in the tropical and temperate seas of the world; generally small.

Family Pleuronectidae (right-eyed flounders)
Eyes dextral; anus on blind side, commonly on or near midline; gill membranes connected; dorsal- and anal-fin rays shortened posteriorly; pelvic-fin bases of ocular side short or long, on blind side short, 3–13 pelvic-fin rays. Forty-three genera with about 100 species, found primarily in northern and Arctic seas, but some occur in tropical and temperate seas.

Suborder Soleoidei
Same as Pleuronectoidei, but preopercular margin not free (covered by skin and scales); lower jaw not prominent; nostrils nearly symmetrical, that on blind side not near edge of head.

Family Soleidae (soles)
Eyes small, dextral; mouth curved downward; sensory or tactile papilla on head (primarily on blind side); caudal fin with numerous rays. Over 100 species found in tropic and temperate seas; many true soles are small and found along the shore, somes species inhabiting freshwater.

Family Cynoglossidae (tongue soles)
Eyes small, sinistral; head large; mouth curved downward, head lacking sensory or tactile papilla; dorsal and anal fins confluent with caudal fin; caudal fin with only about 12 fin rays; generally small, slender fishes, found in tropical seas.

(E.J.G.)

Box fishes, puffer fishes, ocean sunfishes, and allies (Tetraodontiformes)

The order Tetraodontiformes is a group of primarily tropical marine fishes that evolved from the Perciformes (the typical advanced spiny-rayed fishes) during the Eocene Period of the Cenozoic Era, about 50,000,000 years ago. The approximately 320 species of modern tetraodontiforms are notable for a high degree of diversity in anatomical structure and way of life. The great diversity evident among the 11 families of the order is also seen within some families, but not in others. Members of the deepwater, bottom-dwelling Triacanthodidae, the most primitive family, for example, range from relatively normal configurations to weirdly specialized forms with extremely long tubular snouts; the shallow-water members of the Triacanthidae, closely related and derived from the Triacanthodidae, are of rather uniform configuration. Likewise, the balistids are rather uniform in body plan; but monacanthids, which evidently evolved from them, include a series of species ranging from the normal to the exceedingly elongated and highly specialized.

GENERAL FEATURES

The tetraodontiforms make up about 5 percent of the tropical marine fishes of the world. Most species range in size from about eight to 60 centimetres (three to 24 inches) in length, but one ocean sunfish reaches more than three metres (11 feet). They are often strikingly patterned or gaudily coloured. With the exception of the relatively deepwater Triacanthodidae and Triodontidae, the members of this order are usually found in waters less than about 65 metres (200 feet) in depth and are especially prominent around coral or rocky reefs and on open sand and grass flats.

Poisonous flesh

Many species, especially of puffer fishes (Tetraodontidae), have poisonous flesh, at least during certain seasons of the year, but most of the highly poisonous substance (tetraodontoxin) responsible for the numerous annual fatalities in Indo-Pacific regions is contained in the viscera. The flesh of the poisonous species can be safely eaten only when the freshly caught specimen has been carefully cleaned and washed in the exacting manner of fugu (or puffer fish) chefs in Japan. But the majority of tetraodontiforms are palatable, and in numerous tropical regions the flesh of various triggerfishes and trunkfishes is highly esteemed. Other than as food in tropical coastal areas, man makes little direct use of tetraodontiforms, except for the dried bodies of the hard-cased boxfishes and the spine-studded, inflated puffers as curios. In fact, the order Tetraodontiformes contains so many strangely specialized species that the group has intrigued mankind from early times; a 1st-century Roman author, Pliny the Younger, for example, discussed puffer fishes and ocean sunfishes in his *Naturalis Historiae.* While most adult tetraodontiforms have thick, spiny skins or other defensive mechanisms that protect them from most predacious fishes, the young, relatively defenseless stages are eaten in great quantities by certain game fishes—dolphin, marlin and other billfishes, tunas, and various jacks.

From Spencer W Tinker, *Hawaiian Fishes* (1944)

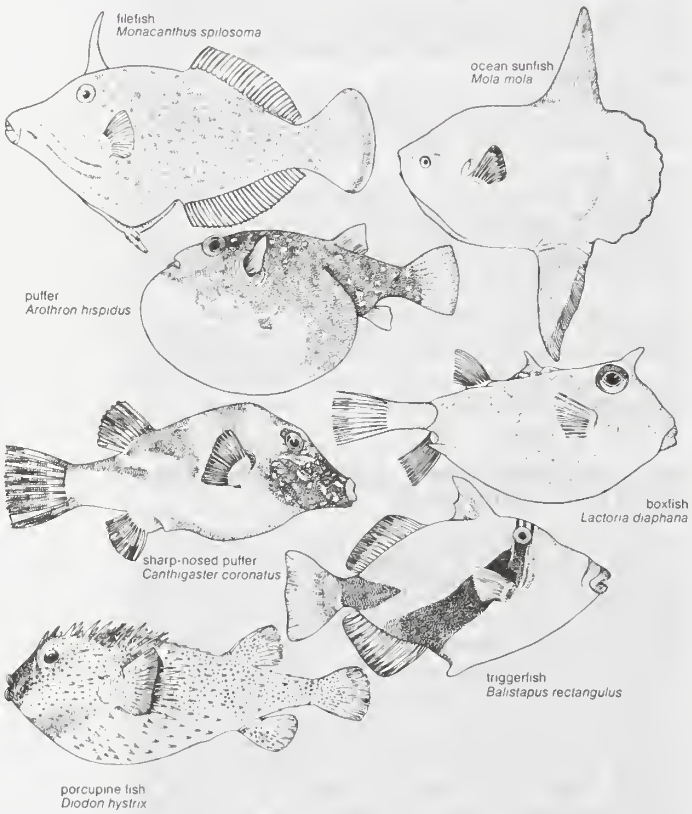

Figure 41: Body plans of representative tetraodontiform fishes.

NATURAL HISTORY

Feeding habits. As one would suspect from their usually well-developed and massive dentition, often with the teeth fused together in a parrotlike beak, most tetraodontiforms feed on hard-shelled crustaceans, mollusks, and echinoderms. But some, with massive, crushing jaws and teeth, such as the ocean sunfishes, often feed extensively on such soft-bodied invertebrates as jellyfishes (medusae). Some, such as boxfishes, blow a jet of water out of their mouths onto sand bottoms to expose burrowing invertebrates; others (such as some triggerfishes) specialize in eating spiny sea urchins or even clams and oysters. A few species, especially the long-snouted Triacanthodidae, have reduced or even rudimentary teeth, some apparently feeding on the scales of other bottom fishes. Other species probably feed on soft-bodied invertebrates, probing with the snout into holes in the bottom or into recesses in outcroppings to obtain food unavailable to less specialized fishes. Although many species have specialized feeding habits, the order as a whole can be considered as comprising opportunistic predators on invertebrates.

Locomotion. Most tetraodontiforms swim by the rather unusual method of rapid undulations or complex scullings of the soft dorsal and anal fins (in the midline of the back and underside, respectively); the powerful caudal fin (except in the Molidae) is reserved for rapid bursts of speed. The paired pectoral fins (just behind the gills) are in an almost constant state of rapid vibration, which gives a delicacy of control to their movements that is unusual even among fishes.

Activity cycle. Those tetraodontiforms for which data are available are diurnal, feeding or otherwise active during daylight but quiescent at night, often retiring to holes or crevices in coral or rocky reefs to sleep. When disturbed during the day, as by a potential predator, some species take rapid flight; others dive into reef crevices. Other species avoid the attention of predators by remarkable colorations or patternings that permit them to blend into the environment, which may be anything from a coral reef to a bed of bottom sea grass. One relatively defenseless species (a filefish), moreover, is an excellent mimic in body form and bright coloration of a spiny-skinned, inflatable, and perhaps poisonous puffer.

FORM AND FUNCTION

The Tetraodontiformes are distinguished externally by a small gill opening restricted to a relatively short slit on the side of the head and a small mouth, usually equipped with massive teeth. The scales of the body are typically highly modified into overlapping (in triacanthoids and balistoids) and even sutured (in ostraciontoids) plates or into sharp, projecting spines (in tetraodontoids and diodontids); in some cases, the skin itself may be thickened and hardened by deep layers of connective tissues (molids). There are no anal fin spines, and the dorsal fin spines are either absent or present only in reduced number (never more than six). The pelvic fin, which in the perciforms has one spine and five soft rays, in tetraodontiforms is either absent or reduced to no more than one spine and two small soft rays. The skeleton of tetraodontiforms is notable for a reduced number of bones, a number of the separate bony elements of the ancestral perciforms having been lost through the processes of reduction, consolidation, fusion, or failure to develop. The hallmark of the evolution and diversification of the tetraodontiforms, in fact, has been the reductive tendencies in some parts—number of skeletal elements, number of fin spines, size of mouth and gill opening, and number of teeth—with the simultaneous elaborative tendencies in other systems—scale and skin development, inflation apparatus, size of teeth and fusion with jawbones, and poisonous flesh.

Fin and skeletal features

CLASSIFICATION

Annotated classification. The Tetraodontiformes are classified as follows, with only the most obvious external differences that distinguish the groups mentioned.

ORDER TETRAODONTIFORMES (PLECTOGNATHI)

Small mouth and gill openings; reduced dorsal and pelvic fin spines; no anal fin spines; skin usually tough or spiny.

Suborder Balistoidei (Sclerodermi)

Teeth separate, discrete, individual units.

Superfamily Triacanthoidea

Six dorsal spines and a large pelvic spine.

Family Triacanthodidae (spikefishes). The most primitive members of the order; deepwater species with a truncated or rounded tail; deep caudal peduncle (the region between the end of the anal fin and the front of the tail); nonstreamlined body; soft dorsal and anal fins of about same length along their bases; Indo-Pacific and Caribbean.

Family Triacanthidae (triple spines). Shallow-water derivatives of the spikefishes; deeply forked caudal fin; slender caudal peduncle; body relatively streamlined for rapid swimming; soft dorsal fin base much longer than anal fin base; Indo-Pacific, sometimes found in estuaries.

Superfamily Balistoidea

Two or 3 dorsal spines, the 2nd spine serving to lock the 1st in an erected position; pelvic spine rudimentary or absent.

Family Balistidae (triggerfishes). Three dorsal spines; 8 outer teeth in each jaw; worldwide.

Family Monacanthidae (filefishes). Two dorsal spines; 6 or fewer outer teeth in each jaw; worldwide.

Superfamily Ostraciontoidea

No dorsal spines, body encased in a turtle-like cuirass (carapace) of sutured, platelike scales.

Family Aracanidae (keeled boxfishes). Carapace open behind the dorsal and anal fins and bearing a ventral keel; usually in deeper water than the ostraciontids; Indo-Pacific.

Family Ostraciontidae (boxfishes, trunkfishes, cowfishes). Carapace closed behind anal and usually behind dorsal fin, no ventral keel; worldwide.

Suborder Tetradontoidei (Gymnodontes)

Teeth more or less fused to the jawbones, forming a parrotlike beak.

Superfamily Triodontoidea

Three tooth plates, 2 in upper and 1 in lower jaw.

Family Triodontidae (pursefish). Most primitive member of the suborder, the only species to retain even the pelvic bone of the pelvic fin apparatus (completely lost by all other members of suborder); body somewhat elongate; 1 species; deep water; tropical Indo-Pacific.

Superfamily Tetraodontoidea

Four tooth plates, 2 in each jaw; the skin bearing small erectile spines.

Family Tetraodontidae (puffer fishes). A large number of species, differing from the sharp-nosed puffers mainly in osteological structure, but always having a prominent nasal apparatus; worldwide.

Family Canthigasteridae (sharp-nosed puffer fishes). Single, inconspicuous nostril on each side of head; snout more laterally compressed than in the tetraodontids; worldwide.

Superfamily Diodontoidea

Two tooth plates, 1 in each jaw; the skin bearing huge spines; caudal fin normal.

Family Diodontidae (porcupine fishes and burrfishes). Characteristics of superfamily. Spines erectile (porcupine fishes) or fixed (burrfishes); worldwide.

Superfamily Moloidea

Two tooth plates, 1 in each jaw. Skin relatively smooth but often exceptionally thick; caudal fin highly modified or absent; swim bladder absent.

Family Molidae (ocean sunfishes). Three species, 2 of which reach enormous size, 1 up to 3.3 metres (11 feet) in length and 1,900 kilograms (4,000 pounds) in weight; tropical and subtropical oceans worldwide.

Critical appraisal. The classification of the order is still in a state of flux, and some authorities are willing to recognize as families only those that are listed above as superfamilies. More important, the ostaciontoids are often recognized as a third suborder of Tetraodontiformes rather than, as above, a superfamily of the suborder Balistoidei. Only recently has the ordinal term Tetraodontiformes come into use; the group still is often called the Plectognathi and its two suborders the Sclerodermi and Gymnodontes. (J.C.T.)

(1977), college-level introductory texts of general ichthyology; J.E. WEBB, J.A. WALLWORK, and J.H. ELGOOD, *Guide to Living Fishes* (1981); and TIM M. BERRA, *An Atlas of Distribution of Freshwater Fish Families of the World* (1981).

Regional works: A.H. LEIM and W.B. SCOTT, "Fishes of the Atlantic Coast of Canada," *Bull. Fish. Res. Bd. Can.*, no. 155 (1966), a good general account, completely illustrated; H.B. BIGELOW *et al.*, *Fishes of the Western North Atlantic*, 5 vol. (1948–66), a comprehensive treatment of the biology of western North Atlantic fishes; J.E. BÖHLKE and C.C.G. CHAPLIN, *Fishes of the Bahamas and Adjacent Tropical Waters* (1968); W.B. SCOTT, *Freshwater Fishes of Canada* (1973); W.A. CLEMENS and G.V. WILBY, "Fishes of the Pacific Coast of Canada," *Bull. Fish. Res. Bd. Can.*, no. 68, 2nd ed. (1961); J. and G. LYTHGOE, *Fishes of the Sea: The Coastal Waters of the British Isles, Northern Europe and the Mediterranean* (1971); W.A. GOSLINE and V.E. BROCK, *Handbook of Hawaiian Fishes* (1960), an excellent handbook of fishes from the central Pacific Ocean; T.C. MARSHALL, *Fishes of the Great Barrier Reef and Coastal Waters of Queensland* (1964); T. KAMOHARA, *Fishes of Japan in Color* (1967); J.T. NICHOLAS, *The Fresh-Water Fishes of China* (1943), somewhat old, but a complete coverage on fishes of eastern Asia; I.S.R. MUNRO, *The Marine and Freshwater Fishes of Ceylon* (1955), an inclusive illustrated account of fishes from the Indian Ocean area; J.L.B. SMITH, *The Sea Fishes of Southern Africa*, 5th ed. (1965); R.H LOWE-MCCONNELL, *Fish Communities in Tropical Freshwaters: Their Distribution, Ecology and Evolution* (1975), a broad review of fishes of Africa, South America, and Asia. Somewhat more local, but applicable to much of North America, are the following: M.B. TRAUTMAN, *The Fishes of Ohio with Illustrated Keys*, rev. ed. (1980); F.B. CROSS, *Handbook of Fishes of Kansas* (1967), and, with J.T. COLLINS, a companion vol., *Fishes in Kansas* (1975); H.D. HOESE and R.H. MOORE, *Fishes of the Gulf of Mexico: Texas, Louisiana and Adjacent Waters* (1977); W.F. SMITH-VANIZ, *Freshwater Fishes of Alabama* (1968); C.L. HUBBS and C. LAGLER, *Fishes of the Great Lakes Region*, rev. ed. (1958); JAMES F. MORROW, *The Freshwater Fishes of Alaska* (1980); and ROBERT J. NAIMAN and DAVID L. SOLTZ (eds.), *Fishes in North American Deserts* (1981).

Natural history: C.M. BREDER and D.E. ROSEN, *Modes of Reproduction in Fishes* (1966), a summary of reproductive behaviour of fishes; N.B. MARSHALL, *Aspects of Deep Sea Biology* (1954), a college-level introduction to deep-sea biology; B.W. HALSTEAD, *Poisonous and Venomous Marine Animals of the World*, vol. 2 and 3, rev. ed. (1978), an extensive treatment of poisonous and venomous marine fishes, beautifully illustrated in colour; H.S. DAVIS, *Culture and Diseases of Game Fishes* (1953), a general aid to the culture of North American game fishes. See also MICHAEL GOULDING, *The Fishes and the Forest. Explorations in Amazonian Natural History* (1981).

Form and function: R.M. ALEXANDER, *Functional Design in Fishes*, 3rd ed. (1974), a short college-level book on functional anatomy of fishes; M.E. BROWN (ed.), *The Physiology of Fishes*, 2 vol. (1957); and W.S. HOAR and D.J. RANDALL (eds.), *Fish Physiology*, 6 vol. (1969–71), advanced general texts; NATO, *Environmental Physiology of Fishes* (1980).

Paleontology and classification: L.S. BERG, *System der rezenten und fossilen Fischartigen und Fische* (1958), a German translation from the second Russian edition, a revised edition of Berg's 1940 classification of contemporary and fossil fishes; A.S. ROMER, *Vertebrate Paleontology*, 3rd ed. (1966), a college-level text with a good review of fish evolution; W.A. GOSLINE, *Functional Morphology and Classification of Teleostean Fishes* (1971), a study of evolutionary relationships among orders of teleost fish.

Bibliographic reference: B. DEAN *et al.* (eds.), *A Bibliography of Fishes*, 3 vol. (1916–23, reprinted 1972), an almost complete bibliography of works on contemporary and fossil fishes up to about 1923.

Agnatha. V.C. APPLEGATE, *Natural History of the Sea Lamprey, Petromyzon marinus, in Michigan*, Spec. Scient. Rep. U.S. Fish Wildl. Serv. 55 (1950), an account of lamprey life history and the pest problem; A. BRODAL and R. FANGE (eds.), *The Biology of Myxine* (1963), an authoritative work by 24 authors; M. EONTAINE, "Formes actuelles de cyclostomes," in P.P. GRASSÉ (ed.), *Traité de zoologie,* vol. 13, pp. 1–172 (1958), the best general account of cyclostomes (well illustrated); M.W. HARDISTY and I.C. POTTER (eds.), *The Biology of Lampreys* (1972), a comprehensive reference; A.J. MARSHALL, "Agnatha," in T.J. PARKER and W.A. HASWELL, *Textbook of Zoology,* 7th ed., vol. 1 (1962), a good account of comparative anatomy, written for university students; E. STENSIO, "Les Cyclostomes fossiles ou ostracodermes," in J. PIVETEAU (ed.), *Traité de paléontologie,* vol. 4, pp. 96–382 (1964); R. STRAHAN, "The Behaviour of Myxinoids," *Acta Zool. Stockh.,* 44:73–102 (1963), the most recent accounts of the subject.

Chondrichthyes (Selachii). J.S. BABEL, "Reproduction, Life History, and Ecology of the Round Stingray, *Urolophus halleri* Cooper," *Fish Bull. Calif. 127* (1967), an excellent natural history study of a ray; H.B. BIGELOW and W.C. SCHROEDER, "Sharks," *Fishes of the Western North Atlantic, Mem. Sears Fdn. Mar. Res.,* no. 1, pt. 1, pp. 59–546 (1948); "Sawfishes, Guitarfishes, Skates and Rays," and "Chimaeroids," *ibid.,* no. 1, pt. 2 (1953), the two most recent cosmopolitan syntheses in spite of emphasis on the western North Atlantic; "A Study of the Sharks of the Suborder Squaloidea," *Bull. Mus. Comp. Zool. Harv.,* vol. 117, no. 1 (1957), a revision of the group; P. BUDKER, *La Vie des requins* (1947; rev. Eng. trans., *The Life of Sharks,* 1971), a nontechnical, authoritative work; J.E. DANIEL, *The Elasmobranch Fishes,* 3rd rev. ed. (1934), a classic treatise on the anatomy of sharks and rays; D.H. DAVIES, *About Sharks and Shark Attack* (1964), an authoritative, nontechnical work about sharks, principally South African species; P.W. GILBERT (ed.), *Sharks and Survival* (1963), a collection of 22 papers about sharks, with emphasis on dangerous species, including a list of documented attacks throughout the world; P.W. GILBERT, R.E. MATHEWSON, and D.P. RALL (eds.), *Sharks, Skates and Rays* (1967), a collection of technical papers covering a wide range of subjects; E.W. GUDGER (ed.), *Archaic Fishes,* Bashford Dean Memorial Volume (1937), contains articles on the anatomy, reproduction, and development, of the frilled shark (*Chlamydoselachus anguineus*), and on natural history and development of Heterodontid sharks; H.W. MCCORMICK and T. ALLEN, with W.E. YOUNG, *Shadows in the Sea: The Sharks, Skates, and Rays* (1963), an authoritative, well-illustrated, nontechnical work; L.H. MATTHEWS and H.W. PARKER, "Notes on the Anatomy and Biology of the Basking Shark (*Cetorhinus maximus*)," *Proc. Zool. Soc. Lond.,* 120:535–576 (1950); P.M. ROEDEL and W.E. RIPLEY, "California Sharks and Rays," *Fish Bull. Calif. 75* (1950), a handbook for identification of California species (of general use on the Pacific coast), illustrated with excellent photographs; A.S. ROMER, *Vertebrate Paleontology,* 3rd ed. (1966), a comprehensive review, with a classification of archaic and recent fishes; H.W. SMITH, *From Fish to Philosopher* (1961), a chapter on the elasmobranchs discusses their evolution and physiological adaptations to marine environment; D.W. STRASBURG, "Distribution, Abundance, and Habits of Pelagic Sharks in the Central Pacific Ocean," *Fish Bull. U.S. Dep. Interior,* 58:335–416 (1958), contains field observations and quantitative data on 12 species; G.P. WHITLEY, *The Fishes of Australia, Part I, The Sharks, Rays, Devil-Fish, and Other Primitive Fishes of Australia and New Zealand* (1940), a nontechnical book about Australian species; CARL GAUS and T.S. PARSONS, *A Photographic Atlas of Shark Anatomy: The Gross Morphology of 'Squalus Acanthias'* (1981).

Crossopterygii. There is virtually no popular literature dealing with this group of fishes. The following are technical in nature: E. JARVIK, "On the Structure of the Snout of Crossopterygians and Lower Gnathostomes in General," *Zool. Bidr. Upps.,* 21:235–675 (1942); J.P. LEHMAN, "Crossopterygii," in *Traité de paléontologie IV,* 3:301–412 (1966); J. MILLOT, and J. ANTHONY, "*Latimeria chalumnae,* dernier des Crossoptérygiens," in *Traité de zoologie,* vol. 13, pp. 2553–2597 (1958); *Anatomie de* Latimeria chalumnae, 2 vol. (1958–66); J.L.B. SMITH, "A Living Coelacanthid Fish from South Africa," *Trans. R. Soc. S. Afr.,* 28:1–106 (1940); K.S. THOMSON, "The Comparative Anatomy of the Snout in Rhipidistian Fishes," *Bull. Mus. Comp. Zool. Harv.,* 131:313–357 (1964).

Dipnoi. H. SWAN, D. JENKINS, and K. KNOX, "Metabolic Torpor in *Protopterus aethiopicus:* An Anti-Metabolic Agent from the Brain," *Am. Nat.,* 103:247–258 (1969), an article on dry sleep in lungfishes; M. BLANC, E. D'AUBENTON, and Y. PLESSIS, "Mission M. Blanc-F. d'Aubenton (1954) IV. Ètude de l'enkystement de *Protopterus annectens* (Owen 1839)," *Bull. Inst. Fr. Afr. Noire,* Series A, 18:843–854 (1956), a study of the encystment of *Protopterus annectens;* P. BRIEN, M. POLL, and J. BOUILLON, "Ethologie de la reproduction du *Protopterus dolloi* (Boulenger)," *15th Int. Congr. Zool.,* sect. 1 (1959); J.S. BUDGETT, "On the Breeding-Habits of Some West-African Fishes, with an Account of the External Features in the Development of *Protopterus annectens,* and a Description of the Larva of *Polypterus lapradei,*" *Trans. Zool. Soc. Lond.,* 16:115–136 (1901); K. CURRY-LINDAHL, "On the Ecology, Feeding Behaviour and Territoriality of the African Lungfish, *Protopterus aethiopicus,* Heckel," *Ark. Zool.,* Series 2, 9:479–497 (1956); A.G. JOHNELS and G.S.O. SVENSSON, "On the Biology of *Protopterus annectens* (Owen)," *ibid.,* 7:131–164 (1955), a detailed study of the habits of lungfishes in the flooding zones on both sides of the Gambia River; K.H. LUELING, "Einige Notizen uber afrikanische Lungenfische," *Dt. Aquar.-Terrar-Z.,* 12:12–14, 44–46 (1959), on the habits and distribution of the African lungfishes, together with a distribution map according to Poll; "Untersuchungen an Lungenfischen, insbesondere an afrikanischen Protopteriden," *Bonn. Zool. Beitr.,* 12:87–112 (1961), a detailed examination of the experimental encysting of the West African lungfish *Protopterus dolloi* in captivity; "Fische mit Lungen," *Neptun,* 6:80–83 (1966), a study of the morphology, anatomy, and the method of breating of lunglike structures in the dipnoi; M. POLL, "Zoogéographie des protoptères et des polyptères," *Bull. Soc. Zool. Fr.,* 79:282–289 (1955), a discussion of the distribution of the four species of African lungfishes, with distribution map; H.W. SMITH, "Metabolism of the Lung-Fish, *Protopterus aethiopicus,*" *J. Biol. Chem.,* 88:97–130 (1930), the first modern physiological study of the encysting of Ethiopian lungfishes in captivity; "Observations on the African Lung-Fish, *Protopterus aethiopicus,* and on Evolution from Water to Land Environments," *Ecology,* 12:164–181 (1931); E.K. SUVOROV, *Allgemeine Fischkunde* (1959; German trans. from the 2nd Russian ed. of 1948), includes a chapter on the breathing organs of Dipnoi.

Chondrostei. S.M. ANDREWS *et al.,* "Pisces," in W.B. HARLAND *et al.* (eds.), *The Fossil Record: A Symposium with Documentation,* ch. 26 (1967), a recent classification of fish, with first and last occurrences for each family; E.S. GOODRICH, "*Vertebrata craniata,*" fasc. 1, "Cyclostomes and Fishes," in E.R. LANKESTER (ed.), *A Treatise on Zoology* (1909), a classic work on the anatomy of fish that is still useful; D. HEYLER, *Vertébrés de l'autunien de France* (1969), a detailed account of some palaeonisciform fish from a classic locality in France; J.P. LEHMAN, "Etude complementaire des poissons de l'Eotrias de Madagascar," *K. Svenska Vetensk-Akad. Handl.,* 2:1–201 (1952), a detailed study of early Triassic fish from Madagascar; "Superordre des Chondrostéens (Chondrostei): Formes fossiles," in P.P. GRASSÉ (ed.), *Traité de zoologie,* vol. 13 (1958), a comprehensive reference work on the organization and classification of the chondrosteans, and "Actinopterygii," in J. PIVETEAU (ed.), *Traité de paléontologie,* vol. 4 (1966); D.V. OBRUCHEV (ed.), *Fundamentals of Paleontology,* vol. 11, *Agnatha, Pisces* (1967); and A.S. ROMER, *Vertebrate Paleontology,* 3rd ed. (1966), two comprehensive reference works.

Holostei. S.M. ANDREWS *et al.,* "Pisces," in W.B. HARLAND *et al.* (eds.), *The Fossil Record: A Symposium with Documentation,* ch. 26 (1967), a recent classification of fish, with first and last occurrences for each family; B.G. GARDINER, "A Revision of Certain Actinopterygian and Coelachanth Fishes, Chiefly from the Lower Lias," *Bull. Br. Mus. Nat. Hist.* (*Geol.*), 4:239–384 (1960), important revised descriptions of early Jurassic fish from Great Britain; E.S. GOODRICH, "*Vertebrata craniata,*" fasc. 1, "Cyclostomes and Fishes," in E.R. LANKESTER (ed.), *A Treatise on Zoology* (1909), a classic work on the anatomy of fish that is still useful; J.P. LEHMAN, "Actinopterygii," in J. PIVETEAU (ed.), *Traité de paléontologie,* vol. 4 (1966), a recent summary of important characteristics of the higher bony fishes, along with their geologic and geographic distributions; D.V. OBRUCHEV (ed.), *Fundamentals of Paleontology,* vol. 11, *Agnatha, Pisces* (1967), a summary treatment of all fishes, living and fossil; D.H. RAYNER, "The Structure and Evolution of the Holostean Fishes," *Biol. Rev.,* 16:218–237 (1941), an attempt to relate the various families of holostean fishes mainly on the basis of braincase design; A.C. WEED, *The Alligator Gar* (1923).

Teleostei. For references to the literature on teleostei, see the following bibliographies for the major teleost groups.

Elopiformes. S.E. HILDEBRAND, "Family Elopidae" and "Family Albulidae," in H.B. BIGELOW *et al., Fishes of the Western North Atlantic,* vol. 3, pp. 111–147 (1963), full discussions of the structure, biology, and classification of ladyfishes, tarpons, and bonefishes; R.A. WADE, "The Biology of the Tarpon, *Megalops atlanticus,* and the Ox-eye, *Megalops cyprinoides,* with Emphasis on Larval Development," *Bull. Mar. Sci. Gulf Caribb.,* 12:545–622 (1962), a detailed account of the biology of the Pacific tarpon, or oxeye, and the Atlantic tarpon; P.H. GREENWOOD, "Skull and Swimbladder Connections in Fishes of the Family Megalopidae," *Bull. Br. Mus. (Nat. Hist.), Zool.,* 19:119–135 (1970), details of the specialized respiratory system of the tarpons; P.L. EOREY, "A Revision of the Elopiform Fishes, Fossil and Recent," *Bull. Br. Mus. (Nat. Hist.), Geol.,* suppl. 10 (1973), a full account of the structure and evolution of elopiforms.

Anguilliformes. L. BERTIN, *Les anguilles,* 2nd ed. (1951; Eng. trans., *Eels: A Biological Study,* 1956), a comprehensive, readable account of the biology of freshwater eels; J. SCHMIDT, "The

Breeding Places of the Eel," *Rep. Smithson. Instn. (1924)*, pp. 279–316 (1925), a summary by the original researcher of the classical biological study of eels; A.E. BRUUN, "The Breeding of the North Atlantic Freshwater-Eels," *Adv. Mar. Biol.*, 1:137–170 (1963), an important review of current controversy regarding the eel life-cycle; L. BERTIN and C. ARAMBOURG, "Anguilliformes," in P.P. GRASSÉ (ed.), *Traité de Zoologie*, 13:2314–2327 (1958), a classical text in French with a good coverage of eels; P.H.J. CASTLE, "The World of Eels," *Tuatara*, 16:85–97 (1968), a general article of college level difficulty, and "An Index and Bibliography of Eel Larvae," *Spec. Publs. Inst. Ichthyol. Rhodes Univ.*, 7:1–125 (1969), a comprehensive bibliographic index to leptocephali; F.W. TESCH, *The Eel: Biology and Management of Anguillid Eels* (1977).

Clupeiformes. P.H. GREENWOOD *et al.*, "Phyletic Studies of Teleostean Fishes with a Provisional Classification of Living Forms," *Bull. Am. Mus. Nat. Hist.*, 131:339–455 (1966), contains the latest classification, which is used also in this article. Some different classifications and arrangements are in: L.S. BERG, "Classification of Fishes, Both Recent and Fossil," *Trav. Inst. Zool. Acad. Sci. U.S.S.R.*, vol. 5, no. 2 (1940; reprinted in book-form, 1947), Russian and English texts; LEON BERTIN and CAMILLE ARAMBOURG, "Super-ordre des téléostéens (Teleostei)," in P.P. GRASSÉ (ed.), *Traité de zoologie*, vol. 13, fasc. 3, pp. 2204–2500 (1958); P.J.P. WHITEHEAD, "A Contribution to the Classification of Clupeoid Fishes," *Ann. Mag. Nat. Hist.*, Series 13, 5:737–750 (1962); H.S. CLAUSEN, "Denticipitidae, a New Family of Primitive Isospondylous Teleosts from West African Freshwater," *Vidensk. Meddr. Dansk Naturh. Foren.*, 121:141–151 (1959), the first scientific description of an unknown and evolutionary important Clupeiformes family; M.B. SCHAEEER, "Men, Birds and Anchovies in the Peru Current: Dynamic Interactions," *Trans. Am. Fish. Soc.*, 99:461–467 (1970), a modern evaluation of the most abundant species resources; A.J. MANSUETI and J.D. HARDY, *Development of Fishes of the Chesapeake Bay Region: An Atlas of Egg, Larval, and Juvenile Stages* (1967); E.K. BALON, "First Catches of Lake Tanganyika Clupeids (kapenta—*Limothrissa miodon*) in Lake Kariba," *Bull. Fish. Res. Zambia*, 5:175–186 (1971), an account of successful artificial introduction into a new area; and A.N. SVETOVIDOV, "Fauna of the U.S.S.R.," *Fishes*, vol. 2, no. 1, *Clupeidae* (1963; originally published in Russian, 1952), a good source of biological and morphological data with extensive bibliography.

Osteoglossomorpha. P.H. GREENWOOD, "On the Genus *Lycoptera* and Its Relationship with the Family Hiodontidae (Pisces, Osteoglossomorpha)," *Bull. Br. Mus. Nat. Hist (Zool.)*, 19:259–285 (1970); and *et al.*, "Phyletic Studies of Teleostean Fishes, with a Provisional Classification of Living Forms," *Bull. Am. Mus. Nat. Hist.*, 131:339–455 (1966), includes the most recent classification of the Osteoglossomorpha and a discussion of the reasons for that arrangement; E.S. HERALD, *Living Fishes of the World* (1961), a popular, well-illustrated account of the various families, and some species, particularly their biology; K.H. LULING, "*Arapaima*, Giant Fish of Amazonas," *Animals*, 11:222–225 (1968), a popular account; G.J. NELSON, "Infraorbital Bones and Their Bearing on the Phylogeny and Geography of Osteoglossomorph Fishes," *Am. Mus. Novit.*, no. 2394 (1969); "Gill Arches of Teleostean Fishes of the Division Osteoglossomorpha," *J. Linn. Soc. (Zool.)*, 47:261–277 (1968); J.R. NORMAN, *A History of Fishes*, 2nd ed. rev. by P.H. GREENWOOD (1963), includes a general account of osteoglossomorph biology, distribution, and anatomy (high school and college level); G. STERBA, *Susswasserfische aus aller Welt* (1959; Eng. trans., *Freshwater Fishes of the World*, 1962), particularly for the aquarist.

Salmoniformes. J.W. JONES, *The Salmon* (1959); W.E. EROST and M.E. BROWN, *The Trout* (1967), two works with general information on Salmoniformes; J.E. EITCH and R.J. LAVENBERG, *Deep-Water Teleostean Fishes of California* (1968), a book designed for the interested layman, covering many deep-sea Salmoniformes; P.H. GREENWOOD *et al.*, "Phyletic Studies of Teleostean Fishes with a Provisional Classification of Living Forms," *Bull. Am. Mus. Nat. Hist.*, 131: 339–455 (1966), created the order Salmoniformes; S.H. WEITZMAN, "The Origin of the Stomiatoid Fishes with Comments on the Classification of Salmoniform Fishes," *Copeia*, pp. 507–540 (1967), created a new suborder Osmeroidei and modified the classification of GREENWOOD *et al.* (above); R.M. MCDOWALL, "Relationships of Galaxioid Fishes with A Further Discussion of Salmoniform Classification," *Copeia*, pp. 796–824 (1969), suggested further modifications in the classification of Salmoniformes; D.E. ROSEN and C. PATTERSON, "The Structure and Relationships of the Paracanthopterygian Fishes," *Bull. Am. Mus. Nat. Hist.*, 141:357–474 (1969), a revision of Salmoniformes with new information on early teleostean evolution; C. PATTERSON, "Two Upper Cretaceous Salmoniform Fishes from the Lebanon," *Bull. Br. Mus. Nat. Hist., Geol.*, 19:207–296 (1970), provides new information and suggested relationships of primitive salmoniforms; W.A. GOSLINE, "The Morphology and Systematic Position of the Alepocephaloid Fishes," *Bull. Br. Mus. Nat. Hist., Zool.*, 18:183–218 (1969), a review of suborder Alepocephaloidei; J.G. NIELSEN and V. LARSEN, "Synopsis of the Bathylaconidae (Pisces, Isospondyli) with a New Eastern Pacific Species," *Galathea Rep.*, 9:221–238 (1968), revises the suborder Bathylaconoidei, family Bathylaconidae in suborder Alepocephaloidei; N.B. MARSHALL, "*Bathyorion danae*, a New Genus and Species of Alepocephaliform Fishes," *Dana Rep.*, 68:1–10 (1966), a technical paper on the suborder Alepocephaloidei; G.J. NELSON, "Gill Arches of Some Teleostean Fishes of the Families Salangidae and Argentinidae," *Jap. J. Ichthyol.*, 17:61–66 (1970), another technical article revising the order Salmoniformes; R.J. BEHNKE, "A New Subgenus and Species of Trout, *Salmo (Platysalmo) platycephalus*, from Subcentral Turkey, with Comments on the Classification of the Subfamily Salmoninae," *Mitt. Hamb. Zool. Mus. Inst.*, 66:1–15 (1968), classification of trouts and salmons, and "The Application of Cytogenic and Biochemical Systematics to Phylogenetic Problems in the Family Salmonidae," *Trans. Am. Fish Soc.*, 99:237–248 (1970), classification of whitefishes, subfamily Coregoninae; STEPHEN D. SEDGWICK, *The Salmon Handbook: The Life and Cultivation of Fishes of the Salmon Family* (1982); GARY A. BORGER, *Naturals: A Guide to Food Organisms of the Trout* (1980).

Ostariophysi. JAMES W. ATZ, *Dean Bibliography of Fishes 1968* (1971), the first volume of a comprehensive, computerized bibliographic series; GEORGE ALBERT BOULENGER, *Catalogue of the Fresh-Water Fishes of Africa*, 4 vol. (1909-16), an important, illustrated, systematic account of Old World tropical groups; PHILIP J. DARLINGTON, JR., *Zoogeography: The Geographical Distribution of Animals* (1957), an excellent account of the distribution of freshwater fishes; CARL H. EIGENMANN and GEORGE S. MYERS (coauthor of pt. 5), *The American Characidae*, 5 pt. (1917–29), a classic treatise, only one-third completed upon death of the author; M.M. ELLIS, "The Gymnotid Eels of Tropical America," *Mem. Carneg. Mus.*, 6:109–204 (1914), a comprehensive, systematic, and morphological study; WILLIAM K. GREGORY and G. MILES CONRAD, "The Phylogeny of the Characin Fishes," *Zoologica*, 23:319–360 (1938), an old, somewhat equivocal, but important contribution on classification; HARRY GRUNDFEST, "Electric Fishes," *Scient. Am.*, 203:115–124 (1960), a semipopular but authoritative article; WILLIAM T. INNES, *Exotic Aquarium Fishes*, 19th ed. (1956), a well-illustrated, informative handbook of popular aquarium fishes; JOHN G. LUNDBERG and JONATHAN N. BASKIN, "The Caudal Skeleton of the Catfishes, Order Siluriformes," *Am. Mus. Novit. 2398* (1969), a description of anatomy, evolution, and relationships; W. PFEIFFER, "Alarm Substances," *Experientia*, 19:113–123 (1963), an excellent review article; C.T. REGAN, "The Classification of the Teleostean Fishes of the Order Ostariophysi," *Ann. Mag. Nat. Hist.*, Series 8, 8:13–32, 553–577 (1911), an old, but historically useful treatise on morphology and classification; JOHN H. TODD, "The Chemical Languages of Fishes," *Scient. Am.*, 244:99–108 (1971), a description of contemporary experiments on communication; STANLEY H. WEITZMAN, "The Osteology of *Brycon meeki*, a Generalized Characid Fish, with an Osteological Definition of the Family," *Stanford Ichthyol. Bull.*, 8:1–77 (1962), an important review of characid classification and osteology; JASPER S. LEE, *Commercial Catfish Farming*, 2nd ed. (1981).

Paracanthopterygii. *General:* C.M. BREDER and D.E. ROSEN, *Modes of Reproduction in Fishes* (1966); E.S. HERALD, *Living Fishes of the World* (1961).

Atheriniformes. R.M. ALEXANDER, "Mechanisms of the Jaws of Some Atheriniform Fish," *J. Zool.*, 151:233–255 (1967), an account of methods of jaw protrusion; C.M. BREDER and D.E. ROSEN, *Modes of Reproduction in Fishes* (1966), especially good on reproductive modifications in atheriniforms, with full bibliography; D.S. JORDAN and C.L. HUBBS, "A Monographic Review of the Family Atherinidae or Silversides," *Stanford Univ. Publs., Univ. Ser., Studies in Ichthyology*, 1:1–87 (1919), a classic review of atherinoids; C.T. REGAN, "On the Anatomy, Classification, and Systematic Position of the Teleostean Fishes of the Suborder Allotriognathi," *Proc. Zool. Soc. Lond.*, pp. 634–643 (1907), a classic paper in which the lampridiforms were first grouped together; R.R. ROEEN, "The Whale-Fishes: Families Cetomimidae, Barbourisiidae and Rondeletiidae (order Cetunculi)," *Galathea Rep.*, 1:255–260 (1959), an illustrated account of these deep-sea forms; D.E. ROSEN, "The Relationships and Taxonomic Position of the Halfbeaks, Killifishes, Silversides and their Relatives," *Bull. Am. Mus. Nat. Hist.*, 127:219–267 (1964), a monograph, with bibliography, in which the Atheriniformes were first grouped together, and with R.M. BAILEY, "The Poeciliid Fishes (Cyprinodontiformes), their Structure, Zoogeography, and Systematics," *ibid.*, 126:1–176 (1963), a monographic account of peociliids, and with C. PATTERSON, "The Structure and Relationships of the Paracanthopterygian Fishes," *ibid.*, 141:359–474 (1969), discussions of the relationships of fossil and living beryciforms, lampridiforms and atheriniforms, with bibliography.

Gasterosteiformes. AMERICAN EISHERIES SOCIETY, *A List of Common and Scientific Names of Fishes from the United States and Canada*, 3rd ed. (1970); LEO BERG, *Classification of Fishes Both Recent and Fossil* (1947), English and Russian; W.A. CLEMENS and G.V. WILBY, *Fishes of the Pacific Coast of Canada*, 2nd ed. (1961), limited in breadth and depth due to few order representatives in that range; EARL S. HERALD, *Living Fishes of the World* (1961); DAVID STARR JORDAN, *Fishes*, rev. ed. (1925), an excellent systematic work, although the nomenclature requires revision (college level); A.H. LEIM and W.B. SCOTT, *Fishes of the Atlantic Coast of Canada* (1966), a work broader in scope than Clemens-Wilby (above); N. TINBERGEN, "The Curious Behavior of the Stickleback," *Scient. Am.*, 187:22–26 (1952), a popularized segment of the author's 1951 *Study of Instinct;* GILBERT WHITLEY and JOYCE ALLAN, *The Sea-Horse and Its Relatives* (1958), a brief, supposedly popularized account of order members in Australian waters—of amazing scope, interest, and depth.

Scorpaeniformes. Most of the information on the scorpaeniform fishes is found in short technical articles in scientific journals. The following works are broad in nature but contain substantial information on members of this order. E.S. HERALD, *Living Fishes of the World* (1961), is a well-illustrated book for the general reader; N.B. MARSHALL, *The Life of Fishes* (1965), contains some sections on the biology of scorpaeniforms; G.V. NIKOLSKII, *Special Ichthyology*, 2nd rev. ed. (1961; trans. of the 2nd Russian ed. of 1954), deals especially with species commercially important in the Soviet Union; B.W. HALSTEAD, *Poisonous and Venomous Marine Animals of the World*, vol. 3 (1970), provides information on the venom of these fishes and its effects. P.H. GREENWOOD *et al.*, "Phyletic Studies of Teleostean Fishes, with a Provisional Classification of Living Forms," *Bull. Am. Mus. Nat. Hist.*, 131: 339–455 (1966); and C.T. REGAN, "The Osteology and Classification of the Teleostean Fishes of the Order Scleroparei," *Ann. Mag. Nat. Hist.*, Series 8, 11:169–184 (1913), are rather technical, but important, contributions to the study of the scorpaeniforms.

Perciformes. Recent books containing many excellent illustrations of perciform fishes and short accounts of the biology of each group are: J.E. BÖHLKE and C.C.G. CHAPLIN, *Fishes of the Bahamas and Adjacent Tropical Waters* (1968), a well-illustrated work with keys for identifying species and excellent summaries of the biology of each family; DAVID STARR JORDAN and BARTON WARREN EVERMANN, *The Fishes of North and Middle America*, 4 vol. (1896–1900, reprinted 1963); T.C. MARSHALL, *Fishes of the Great Barrier Reef and Coastal Waters of Queensland* (1964), contains many colour and black-and-white pictures of perciform fishes; I.S.R. MUNRO, *The Fishes of New Guinea* (1967), 1,095 fishes illustrated by photographs, with 76 species in colour; J.L.B. SMITH, *The Sea Fishes of Southern Africa*, 4th ed. (1961), profusely illustrated with many colour plates; J.L.B. and MARGARET M. SMITH, *The Fishes of Seychelles* (1963), 880 species illustrated, many in colour; A.C. WHEELER, *The Fishes of the British Isles and North-West Europe* (1969); JOHN E. RANDALL, *Caribbean Reef Fishes* (1968), contains many fine photographs of perciforms and others; ROBERT B. CHIASSON, *Laboratory Anatomy of the Perch*, 3rd ed. (1980).

Other books with information about perciform fishes are EARL S. HERALD, *Living Fishes of the World* (1961); N.B. MARSHALL, *The Life of Fishes* (1966); and U. OKADA, *Fishes of Japan* (1955).

References pertaining to classification and relationships include: W.C. EREIHOEER, "Patterns of the Ramus Lateralis Accessorius and Their Systematic Significance in Teleostean Fishes," *Stanford Ichthyol. Bull.*, 8:79–189 (1963); and "Trunk Lateral Line Nerves, Hyoid Arch Gill Rakers, and Olfactory Bulb Location in Atheriniform, Mugilid, and Percoid Fishes," *Occ. Pap. Calif. Acad. Sci.*, no. 95 (1972); W.A. GOSLINE, "Systematic Position and Relationships of the Percesocine Fishes," *Pacif. Sci.*, 16:207–217 (1962); "The Suborders of Perciform Fishes," *Proc. U.S. Natn. Mus.*, 124:1–78 (1968); and *Functional Morphology and the Classification of Teleostean Fishes* (1971); P.H. GREENWOOD *et al.*, "Phyletic Studies of Teleostean Fishes, with a Provisional Classification of Living Forms," *Bull. Am. Mus. Nat. Hist.*, 131:339–455 (1966); D.E. MCALLISTER, "The Evolution of Branchiostegals, and Associated Opercular, Gular, and Hyoid Bones, and the Classification of Teleostome Fishes, Living and Fossil," *Bull. Natn. Mus. Can.*, no. 221 (1968); C.T. REGAN, a series of papers on perciform classification in *Annals and Magazine of Natural History*, series 7, vol. 11 and series 9, vol. 11 (1903–23); and "Fishes," *Encyclopaedia Britannica*, 14th ed., vol. 9, pp. 305–328 (1929), which still forms the major basis of present perciform classification; D.E. ROSEN, "The Relationships and Taxonomic Position of the Halfbeaks, Killifishes, Silversides, and Their Relatives," *Bull. Am. Mus. Nat. Hist.*, 127:217–267 (1964), and with COLIN PATTERSON, "The Structure and Relationships of the Paracanthopterygian Fishes," *Bull. Am. Mus. Nat. Hist.*, 141:357–474 (1969).

Pleuronectiformes. J.T. CUNNINGHAM, *A Treatise on the Common Sole,* Solea vulgaris, *Considered Both as an Organism and as a Commodity* (1890), a monograph on the morphology, development, life history, and economics of this species, including a taxonomic review; C.L. HUBBS, "Phylogenetic Position of the Citharidae, a Family of Flatfish," *Misc. Publs. Mus. Zool. Univ. Mich.*, no. 63, pp. 5–38 (1945), presents a definition of the family Citharidae and phylogenetic relationships of the flatfish families; H.M. KYLE, "Flat-fishes (Heterosomata)," *Rep. Danish Exped. Medit.* 2:1–150 (1913), a major treatise on the development of some flatfishes in the families Bothidae, Soleidae, and Cynoglossidae (illustrations of larvae included when known); and "The Asymmetry, Metamorphosis and Origin of Flatfishes," *Phil. Trans. R. Soc.*, Series B, 211:75–129 (1921), a major paper on the origins of pleuronectiform metamorphosis; J.R. NORMAN, *A Systematic Monograph of the Flatfishes (Heterosomata)*, vol. 1, *Psettodidae, Bothidae, Pleuronectidae* (1934), a classic on the taxonomy of flatfishes, the only paper dealing with these families on a worldwide basis; B. BENNET RAE, *The Lemon Sole* (1978).

Tetraodontiformes. J.E. BÖHLKE and C.C.G. CHAPLIN, *Fishes of the Bahamas and Adjacent Tropical Waters* (1968), includes an excellent combination of scientific and popular accounts of the Caribbean tetraodontiforms, with all of the species well illustrated. BRUCE W. HALSTEAD, *Poisonous and Venomous Marine Animals of the World*, vol. 2, *Vertebrates*, rev. ed. (1978), contains a comprehensive review of the poisonous properties of the tetraodontiforms, with numerous illustrations of poisonous species. JAMES C. TYLER, *A Monograph on Plectognath Fishes of the Superfamily Triacanthoidea* (1968), is a technical monograph on the two most generalized families of tetraodontiforms but also includes general accounts of the way of life, the distribution, and the relationships of these families, as well as an extensive bibliography on related articles.

Commercial Fishing

Fishing, which involves the recovery of food and other valuable resources from bodies of water, is one of the oldest employments of mankind. Ancient heaps of discarded mollusk shells, some from prehistoric times, have been found in coastal areas throughout the world, including those of China, Japan, Peru, Brazil, Portugal, and Denmark. These mounds, known as kitchen middens (from the Danish *køkkenmødding*), indicate that marine mollusks were among the early foods of humans.

Archaeological evidence shows that humans next learned to catch fishes in traps and nets. These ventures were limited at first to the lakes and rivers, but as boats and fishing devices were improved, humans ventured into sheltered coastal areas and river mouths and eventually farther out onto the continental shelves, the relatively shallow ocean plains between the land and the deeper ocean areas. In some shelf areas where seaweed was abundant, this was also incorporated into the diet.

Fishing technology continued to develop throughout history, employing improved and larger ships, more sophisticated fishing equipment, and various food preservation methods. Commercial fishing is now carried on in all types of waters, in all parts of the world, except where impeded by depth or dangerous currents or prohibited by law. Commercial fishing can be done in a simple manner with small vessels, little technical equipment, and little or no mechanization as in small local, traditional, or artisanal fisheries. It can also be done on a large scale with powerful deep-sea vessels and sophisticated mechanical equipment similar to that of modern industrial enterprises.

Both plants and animals are taken from the sea. Two types of fish are caught: demersal, living at or near the bottom, although sometimes in mid-water; and pelagic, living in the open sea near the surface. Cod, haddock, hake, pollock, and all forms of flatfish are common demersal fish. Herring and related species and tuna and their relatives are examples of pelagic fish. Both demersal and pelagic fish can sometimes be found far from coastal regions. Other aquatic animals that may be the object of commercial fishery include, most notably, crustaceans (lobsters, spiny lobsters, crabs, prawns, shrimps, crayfish) and mollusks (oysters, scallops, mussels, snails, squid, octopuses). Certain mammals (whales, porpoises), reptiles (serpents, crocodiles), amphibians (frogs), many types of worms, coelenterates (coral, jellyfish), and sponges are also sought by commercial fishermen. Most of these animals are legally regarded as fish in many countries.

The most important water plants commercially obtained in seawater and fresh water are algae. Seaweed is harvested in the water or collected on the seashore. Algae play an important ecological role in many countries, not only as human food but also as fodder for cattle, as fertilizer, and as a raw material for certain industries.

Fisheries are classified in part by type of water: fresh water—lake, river, and pond—and salt water—inshore, mid-water, and deep sea. Another classification is based on the object—as in whaling, salmon fishing, and sponge fishing. Sometimes fisheries are classified according to the method of fishing employed: harpooning, seining, trawling, and lining.

Whaling, historical and modern, has been documented in records from Neolithic cave art to present-day annual reports of the International Commission on Whaling, with no firm proof as to what people first engaged in this dangerous activity. Lacking adequate agriculture, early inhabitants of the polar littoral developed successful whaling techniques using Stone Age weapons. When first contacted, the Inuit (Eskimos) of eastern and western North America showed mastery in whale hunting, and much the same methods were in use up to 1900. For them a captured whale supplied food, fuel, and light; sinews provided cordage, and skeletal parts were used for tools and construction. Not until the 20th century, when floating factories came into use, did another civilization succeed in the same efficient use of the whole carcass. A possible exception is Japan, where whale flesh has been popular from early times. Elsewhere, however, from the first intensive exploitation of whales in the early 17th century to quite recent times, little more than blubber was used, the remainder being discarded. Each successive discovery of a new whaling ground resulted in the near disappearance of a particular species. The efficiency of modern hunting methods speeded this trend to the point that the industry has all but taken its place in history, leaving only a few enterprises to carry on in a limited fashion.

This article discusses organized fishing for profit, with an emphasis on mechanized industrial methods, gear, and vessels. The history and methods of whaling, which is less fishing than the hunting of an aquatic mammal, are discussed separately in this article from freshwater and saltwater fishery and aquaculture. For angling, or recreational fishing, see the *Micropædia* article FISHING. For information on the use and value of fish and marine products as food, see the *Macropædia* article NUTRITION.

(A.v.B./G.A.B./P.F.P./Ed.)

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 731.

This article is divided into the following sections:

History of commercial fishing

Food-gathering people first obtained fish and shellfish from the shallow water of lakes and along the seashore, from small ponds remaining in inundation areas, from tidal areas, and from small streams. Some authorities believe that in the earliest times fish were rarely caught because of the inadequacy of fishing gear. Shellfish, however, can be gathered easily by hand, and the prehistoric kitchen middens indicate their importance as a food source.

In earliest times most foodstuffs were used at once and not stored, but as expanding populations increased food needs, techniques were developed for preserving fish by drying, smoking, salting, and fermentation. It became desirable to catch large quantities, and specialized equipment was devised. Individual fishing was replaced by collective efforts involving larger, more effective gear.

Fishing equipment and methods improved through the centuries, until bulk fisheries were established in Europe. Herring were caught in huge numbers in northern Europe in the Middle Ages. Cod fishery began on the Grand Banks of Newfoundland even before the Italian explorer John Cabot made his voyage there in 1497. Whaling with large fleets began in the 17th century, both in the Atlantic and in the South Pacific.

Fishing under sail

Before mechanization came to the fishing industry toward the end of the 19th century, sailing vessels developed to suit conditions and fisheries in different areas. The Grand Banks schooners were the peak of such developments. Sailing from New England, Nova Scotia, and Newfoundland, they fished cod during trips lasting up to six months, salting the catch for export to Europe, Africa, and the Caribbean. Individual fishermen fished from small wooden dories, setting and hauling longlines by hand. Portuguese vessels also sailed annually to the Grand Banks, and a number still operated alongside modern steel vessels into the late 20th century. Smaller cutters and yawls worked around Europe using drift gill nets and setnets. Beam trawls were used extensively in the North Sea and English Channel, particularly for flatfish, being towed downwind under sail and then hauled back to the vessel's side.

As steam-driven winches came into use, fishing gear increased in size and weight. Steam gradually replaced sail for propulsion in the last quarter of the 19th century. In turn, the internal-combustion engine supplanted steam, although steam trawlers continued operating as late as the 1950s. Smaller craft became motorized in the early 20th century, and the inboard diesel engine became universally adopted—except for the smallest boats, on which gasoline-powered outboard engines remain common.

Larger catches could be obtained by increasing the number or the size of the fishing gear or both. Simple lines armed with one or a few hooks were replaced by longlines with thousands of hooks. Single small traps were combined into systems of hundreds, and pots were set in large quantities. Nets were greatly enlarged; netmaking machines were invented that produced netting in large sheets. Mechanical netmaking brought replacement of the old local netting fibres (linen and hemp) with cotton and hard fibres. But all natural fibres, especially those of cellulose, begin to rot in time; thus, the introduction after World War II of rot-proof nets made of synthetic fibres represented a major advance. Mechanical netmaking remained unchanged for the most part, though for certain fishing gear the usual knotted netting was replaced by knotless netting.

Mechanized net handling

In the beginning of the 1950s, mechanization took a great stride forward in purse seining when the power block was invented for hauling the gear. Another important hauling device was a power-driven drum to haul and store seine nets, gill nets, purse seines, and even the large trawl nets. The Japanese introduced drums in longline fishing for tuna. Another important innovation was the stern chute for stern trawlers, a development made possible by cooperation between naval architects and fishing-gear experts, which permitted large-scale mechanization of gear handling.

An era of rapid technical development in vessel design began with the British factory trawler experiment in the late 1940s, which demonstrated the great advantage of large stern trawlers that processed their catch on board. The idea was quickly developed by countries seeking to fish distant resources, and by the mid-1960s these large vessels (up to 100 metres long) were operated by the Soviet Union, the United Kingdom, Japan, Poland, East Germany, and Spain.

Equivalent development occurred in the exploitation of the huge resources of small pelagic fish, mainly for conversion into fish meal. In the late 1940s small vessels, using hand-operated natural-fibre nets, fed small shore-based canning and fish-meal plants. By the late 1960s, large fleets of 25-metre purse seiners were supplying factory mother ships capable of handling up to 3,000 tons per day.

Concurrently, developing countries strove to introduce more modern fishing technology in order to boost protein supplies for their populations. Most rely heavily on artisanal fishing, using canoes or small boats with simple gear and often working off of open beaches. The introduction of outboard motors, larger boats, and synthetic nets enabled many countries to increase their catches significantly.

In the 40 years following World War II, the annual world fishing catch quadrupled. By the early 1970s, though, it had become apparent that such development was not limitless. Several of the largest resources of pelagic fish harvested by purse seiners suffered collapses generally blamed on overfishing. These included the northeast Atlantic herring, the South Atlantic pilchard, and the West African sardine and associated species. Severe declines in catches of stocks fished by fleets of factory trawlers caused such concern that coastal states pressed for protection of the resources off their shores. In 1972 Iceland became the first country to claim an extended fisheries limit of 50 miles (93 kilometres) and, in 1975, 200 miles. Other countries followed suit, and in 1983 the Law of the Sea established an exclusive economic zone, or EEZ, of 200 miles, inside of which each country had exclusive right to the exploitation of marine life. An immediate result was the exclusion from many areas of high-performance, long-distance foreign fleets, which were replaced by often less-efficient domestic coastal craft. For example, the British fleet of 168 distant-water trawlers disappeared within a few years, to be replaced by a fleet of compact, coastal-type vessels.

Rising fue costs

The oil crisis of the 1970s increased fuel costs as much as 400 percent, while fish prices rose by only about 80 percent. This forced many fuel-inefficient vessels, such as many of the U.S. Gulf shrimp trawlers, to tie up or transfer to other fisheries. Resulting development of fuel-efficient vessels, engines, fishing methods, and equipment—including applications of modern sail technology—depended thereafter upon the price of oil.

With the growing importance of managing fisheries to ensure maximum possible benefit from a particular stock, the work of fisheries scientists increased in importance. From a mainly descriptive science in the 19th century, the field evolved, especially after World War II, to develop sophisticated computer analyses based on mathematical models to predict the optimum yields available from fish populations. (For a history of the whaling industry, see below *Whaling.*)

Fishery equipment and facilities

GEAR

An international classification of fishing methods includes 16 categories, depending upon the fishing gear and the manner in which the gear is used: (1) fishing without gear, (2) grappling and wounding gear, (3) stunning, (4) line fishing, (5) trapping, (6) trapping in the air, (7) fishing with bag nets, (8) dredging and trawling, (9) seining, (10) fishing with surrounding nets, (11) driving fish into nets, (12) fishing with lift nets, (13) fishing with falling gear, (14) gillnetting, (15) fishing with entangling nets, and (16) harvesting with machines.

Hand tools. The simplest and oldest form of fishing, collecting by hand, is still done today by both professionals and nonprofessionals along the shore during ebb tide in shallow water and in deeper water by divers with or without diving suits. Even when small tools such as knives or hoes are used, such collecting is classified as without gear. Diving to collect sponges, pearl oysters, or corals belongs under this classification, as does fishing with hunting animals. The Chinese still use trained otters, and the Japanese sometimes employ cormorants.

To extend the reach of the human arm, long-handled tools were invented, such as spears, which can be thrust, thrown, or discharged, and clamps, tongs, and raking devices for shellfish harvesting. A special form is the harpoon, composed of a point and a stick joined together by a rope. Such grappling and wounding gear also includes spears, blowpipes, bows and arrows, and rifles and guns, which are used in fish shooting.

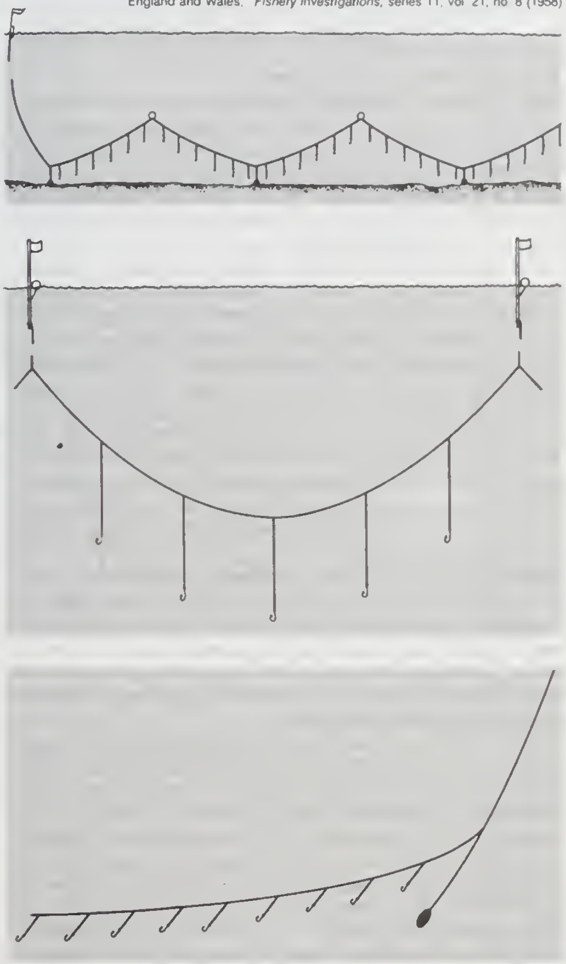
The method called stunning may involve poisoning with toxic plants and special chemicals or mechanical stunning by explosions under water. The most modern practice in this field is to stun the fish by means of an electrical shock.

Lines. In line fishing the fish can be attracted by a natural or artificial bait or lure devised to catch and hold the fish. Generally, the bait is combined with a hook or with a gorge, as is used in France in line fishing for eels. There are handlines, as in pole-and-line fishing for tuna; setlines, such as bottom longlines with hundreds of hooks, used for cod or halibut; drift lines with a single hook and drifting longlines for tuna, shark, and salmon; and troll lines for mackerel and some game fish. Another method of fishing with hooks is done without bait, by raising and lowering arrays of hooks to gig (hook in the body) such large species as cod and sturgeon.

Handlines,
longlines,
and troll
lines

Traps. Genuine mechanical traps, which close by a mechanism released by the prey, are seldom employed for fishing. Most commercial fishing traps are chambers entered easily by the prey but from which escape is prevented by labyrinths or retarding devices, such as gorges or funnels. Fish traps can be simple hiding places, such as bushes or tubes, into which fish or shrimps swim for shelter but cannot escape later when the device is hauled in. The octopus pot used on the Italian coast and by the fishermen of South and East Asia is an example. Other types include small basketlike or cagelike traps made of wood, netting, wire, or plastic pots and fyke nets (long bag-shaped nets kept open by a series of hoops). Large pound nets, composed of net walls that guide fish through a series of baffles into a catching area, are used in the Mediterranean for tuna, off the western Baltic coast for eels, herring, and other species, and off both coasts of the northern Pacific for salmon. A special class are aerial traps for catching flying fish and shrimps. The fish are stirred up, then caught in the air with the help of special gear called veranda nets. South Sea islanders catch flying fish at night by attracting them with torches.

From A. von Brandt, *Fish Catching Methods of the World*, 3rd ed. (1984), Fishing News Books Ltd., after (top) N. Peters, *Handbuch der Seefischerei Nordeuropas* 4 (1935), and (bottom) F.M. Davis "An Account of Fishing Gear of England and Wales," *Fishery Investigations*, series 11, vol. 21, no. 8 (1958)



(Top) Bottom longline, (centre) drifting longline, (bottom) troll line.

Nets. *Bag nets.* Bag nets are kept vertically open by a frame and held horizontally stretched by the water current. There are small scoop nets that can be pushed and dragged and big stownets, with and without wings, held on stakes or on anchors with or without a vessel. There is also a special winged type with boards or metal plates (called otter boards) that keep it spread open. Stownets, larger than scoop nets and held in place against a current, are used in many rivers and by the Koreans for sea fishing in the strong current off the southwest coast of their country. In this case the stownet is anchored with a vessel.

Dragged nets. Dragged gear includes dredges, which are used mostly for shellfish and may be operated by hand in shallow waters or towed from large vessels. Another dragged net is the trawl, a large, cone-shaped bag of netting that is dragged along the seabed or towed in mid-water between the seabed and surface. Trawls are the most important fishing gear of the commercial fisheries of northwest Europe and are second only to purse seines in total catch of the world.

Seines. The seine net has very long wings and towing warps (tow lines), with or without bags for the catch. With purse seines, pelagic fish are surrounded not only from the side but also from underneath, preventing them from escaping by diving downward. Purse seines can be operated by a single boat, with or without auxiliary skiff, or by two vessels. Many sardinelike fishes—herring, tuna, mackerel, cod, and salmon—are commercially fished in this manner.

of seine
fishery

Drive-in and lift nets. Another class of fishing methods involves driving the fish into a net or gear. A drive-in net may be one of those already mentioned or may be specially made, such as the dustpan-shaped stationary gear used in some fisheries in South Asia.

A further fishing method employs lift nets, which are submerged, then raised or hauled upward out of the water to catch the fish or crustaceans above them, often attracted by light or natural bait. This group includes small hand-operated lift nets, such as hoop and blanket nets, as well as large, mechanically and pneumatically operated lift nets. Some of these employ levers, or gallows, and are installed on the beach or on a vessel. The fish wheels used on the Tiber, Rhône, and Columbia rivers can be considered as mechanized lift nets. The most important examples of this fishing method are the stick-held dip nets of the Japanese. In contrast to the lift nets are falling gear, which can be wooden baskets, cover pots, or a variety of nets designed to be cast on fish and crustaceans from above.

Gill and entangling nets. Gill nets, which catch the fish in their meshes, are mostly used in long rows. As setnets they are anchored or fixed by stakes; as drift nets they drift freely or with a fishing craft. Before the invention of mid-water trawls, drift nets, with surrounding nets, were the principal gear for fishing pelagic fishes.

Sometimes gill nets do not catch by meshing but by entangling the fish, especially those too large for the mesh size or provided with spines or hard fins. Single-walled tangle nets are widely used to catch sturgeon, salmon, and shellfish, such as the king crab. Some tangle nets are double walled; most are triple walled, such as the trammel nets used especially for flatfish.

Machines. Harvesting machines include comparatively new types of gear that may separate the fish or shellfish from the water by pumps (pump fishing) or by mechanized dredges, as well as floating machines that dig out mollusks by means of underwater jets and transport them out of the water with the help of conveyor belts.

(A.v.B./J.C.Sa.)

VESSELS

Until the mid-20th century, fishing boats were largely of local design, with different types found even in adjacent ports. As fishermen started to roam farther afield for their catches, the vessels grew, and with this growth in size came an element of standardization in design. Today, fishing boat design and construction is an international industry, with the different vessel types dictated more by the fishing methods for which they are designed rather than by their port or country of origin.

The establishment of 200-mile fishing limits (see above *History of commercial fishing*) has altered fishing patterns and, with them, the types of vessels used by many countries. In the United States and Canada, fishing vessels have grown with the introduction of processing or factory trawlers, while the huge fleets of this type of vessel operated by Soviet-bloc countries and Japan have shrunk. In western Europe, compact fishing vessels have been developed with high catching power. The advantage of these smaller vessels is their reduced capital and operating costs.

Construction materials

Steel is the most common construction material, being used exclusively on larger vessels (above 25 metres). Traditional wood construction is less common because of cost and a lack of suitable timber in many areas. The use of fibreglass is increasing in smaller fishing vessels, and it is now used on vessels of up to 25 metres in length. Ferrocement has been used to a certain extent; it is mainly used in the artisanal fisheries of developing countries because, while its construction is labour intensive, its raw materials are cheap.

The aim in all fishing-boat development is to improve efficiency by building vessels that have higher catching power, smaller crews, and reduced operating costs. This development must be matched against safety concerns, as commercial fishing is one of the highest risk industries in the world. Several countries have introduced regulations governing the construction and operation of fishing vessels. The International Maritime Organization, convened in 1959 under the auspices of the United Nations, is responsible for devising international regulations covering such aspects of fishing vessel design as construction, stability, safety equipment, and watertight integrity. These regulations are likely to lead to further standardization in design.

The Food and Agriculture Organization of the United Nations has introduced a classification scheme of fishing vessels based primarily on the gear used.

Trawlers. Most trawlers are single-screw vessels with powerful engines and deck machinery for dragging the trawl nets.

Side trawlers. On this traditional type of trawler, the trawl is launched and recovered from the side of the vessel. The side trawler is characterized by the wheelhouse and superstructure at the stern and a raised forecastle at the bow. The hull lines follow a traditional seaworthy form, with a pronounced deck sheer giving a high bow and stern. The working deck may be covered.

Stern trawlers. Practically all trawlers built today are stern trawlers, with the trawl launched and recovered over the stern. The vessels are generally designed with the wheelhouse and superstructure forward, often forming part of the raised forecastle. By contrast, the working deck aft is lower, and, on the larger trawlers a ramp is built into the stern up which the trawl is pulled onto the deck. On smaller stern trawlers the trawl is lifted on board by a hoist.

Beam or outrigger trawlers. With this type of vessel, two beam trawls are towed from booms extending to each side and supported by a central mast. The booms are very strong, as they take the full weight of the trawl being towed. The mast supporting the booms may be located forward, in which case the wheelhouse is located aft as on a side trawler, or they may be amidships with the wheelhouse forward, as on a stern trawler. The former type is widely used for beam trawling in Europe, while the latter is the pattern of most shrimp trawlers. European-style beam trawlers are the most powerful fishing vessels of their size in the world.

Shrimp trawlers

Wet-fish trawlers. This type is distinguished by the way the catch is stored on board. It can be either a side or stern trawler with an insulated hold where the fish are stored "wet," or fresh, after sorting. Ice used to cool the catch may be loaded at the start of the voyage or produced on board. This type of trawler normally operates on fishing trips lasting less than four days.

Freezer trawlers. On this type, constituting most large trawlers, the catch is preserved by freezing. On some vessels the catch is gutted and sorted before freezing, but processing is done mainly after the catch is landed.

Factory or processing trawlers. These are the largest type of fishing vessel. After catching and sorting, the fish is transferred to the processing deck, where it is processed and packaged. It is then frozen and stored in the hold. Many vessels have facilities for extracting oil and for making fish meal from waste products. Factory trawlers accommodate large crews and stay at sea for many weeks. They often support a fleet of smaller trawlers; when they

Dag Pike

load fish from other vessels rather than catching it themselves, they are called Klondykers.

Seiners. Seiners range in size from canoes, where the net is hauled by hand, to larger vessels with powerful net-handling equipment. This equipment generally consists of a power block mounted on a crane placed aft of the wheelhouse, as well as winches and drums for hauling and storing the great lengths of net and rope required for seine fishing.

Purse seiners. In purse seining, the fish shoal is surrounded by the net, which has a rope that seals the bottom of the net to trap the fish. Small fish may be pumped out of the net, or the net can be hauled on board and the fish released for sorting.

North American and European purse seiners

The North American purse seiner is generally laid out with a forward wheelhouse and aft working deck. A characteristic of this vessel is the powerful net block on the end of a long boom supported by the mast and a crow's nest on the mast for spotting fish shoals.

European purse seiners are generally larger than their North American counterparts, being typically 30 metres in length. They have an aft wheelhouse and the net is hauled at the stern. The herring and mackerel caught by these vessels, needing sensitive handling and storage, are stored in tanks of chilled seawater built amidships in the hull. Thrusters (screws that provide sideways movement) are usually fitted to these vessels to give improved maneuverability when laying and hauling nets.

Tuna purse seiners are large vessels mainly designed for long-range fishing, although smaller types operate in the Mediterranean. They are similar in design to, but larger than, the North American purse seiner, and they have a sloping stern where a tuna skiff, used for laying the net, is stowed. Several smaller boats are also carried to help with handling the catch and removing unwanted or protected fish from the nets. In addition to a crow's nest for spotting fish shoals, a light helicopter is sometimes carried on a helicopter deck above the forward wheelhouse. Modern tuna vessels store the catch in chilled seawater tanks.

Seine-netters. These vessels, like the European purse seiner, have the wheelhouse placed aft. Rather than purse seines, they employ nets similar to bottom trawls, which they set on long ropes and then haul in along the bottom like seine nets. Winches and reels on the forward deck haul and stow the ropes, while a power block aft hauls in the net.

Dredgers. These vessels tend to fish in sheltered and shallow waters for certain types of shellfish. They are similar to beam trawlers, but they may have four booms for towing the dredges. The hulls are often shallow-draft, and hand or mechanical sorting facilities are fitted on deck. They may have forward or aft wheelhouses.

Lift-netters. These vessels catch fish by lowering nets over the side, switching on powerful lights to attract the fish, and then lifting the net. Their main characteristics are long booms and support masts along the working side of the vessel. Lift-netters are generally low-powered vessels working on short trips.

Gill-netters. Gill nets are used by all sizes of fishing boat up to 20 metres in length. There is no characteristic style, although this type of vessel often uses a steadying sail to keep heading into the wind. The nets may be set and hauled by hand or by power blocks at deck level.

King crab potters

Potters. These are generally inshore vessels using pots or traps to catch shellfish. They come in a wide variety of types and sizes, but a typical inshore potter is 10 metres in length. King crab potters working off of the coast of Alaska are up to 30 metres in length; they generally have the wheelhouse forward to leave a clear working deck aft, but smaller vessels can have the wheelhouse at either end. A characteristic of potters is the pot stowage, which is usually a large frame construction aft. Gear is handled with a crane on larger vessels and with a bulwark-mounted pot hauler on smaller vessels.

Liners. Fishing with lines and hooks is carried out by a wide range of vessels using either manual or mechanical hauling.

Handliners. These are generally small fishing boats, open or decked, working inshore waters.

Longliners. These tend to be larger vessels with the hooks and lines attached to a rope that is supported by floats or simply trailed. Usually there is an automatic line system whereby the hooks are baited and fish removed mechanically in what can be a continuous system. As line-caught fish tend to be of the best quality, chilled seawater tanks are often installed to maintain freshness. The largest types of longliner are those fishing for tuna; these can be more than 60 metres in length.

Pole-and-line vessels. These vessels use lines mounted on poles or fishing rods, hand operated on smaller vessels and mechanized on larger vessels. A large crew is required, and, typically, the vessels are built with the entire deck edge clear to give the maximum fishing area. The wheelhouse can be forward or aft.

E R Degginger/Bruce Coleman Inc

Trollers. On trollers the lines are trailed aft from twin booms. These vessels are similar to beam trawlers, but they have much lighter gear and almost invariably have the wheelhouse forward so that the lines can be hauled in on the working deck aft.

Multipurpose fishing boats. Because fishing for certain species of fish is often seasonal, many modern fishing boats are designed to incorporate two or more different fishing methods. Typical is the trawler/purse seiner, but potting vessels and longliners can also be equipped for trawling. Trawlers can also work at pair trawling, in which a trawl is pulled between two vessels. This may require heavier gear to handle the larger trawl.

Artisanal fishing boats. These are generally used in less-developed countries, working off of an open beach and using very basic fishing methods with no mechanization. Sails and oars are often used as motive power, but under government aid programs there have been advances in design, and engines—mainly outboard motors—are becoming common. Many of the advanced designs retain traditional characteristics to make them acceptable to the fishermen.

Mother ships. This category generally covers vessels carrying small fishing boats that return to the mother ship with their catch. They are generally ocean-going vessels with extensive on-board facilities for processing and freezing the catch. The category can also include factory trawlers supporting a fleet of smaller catching vessels that are not carried on board.

Support and ancillary vessels. Large fishing fleets may be provided with support from rescue and hospital ships so that they are fully self-sufficient. Fishery protection vessels also may incorporate similar facilities, although their primary role is the enforcement of fishing rules and regulations—particularly those relating to fishery limits. These vessels are usually armed in order to ensure compliance with their requests and are often naval vessels. Training vessels and fishery research vessels are usually equipped for different fishing methods, but they have additional facilities to meet their particular functions.

Fishery protection

Pacific salmon troller.

Freshwater fishing boats. Most of these use net and line methods rather than trawls and are therefore lighter in construction than their seagoing counterparts. They are generally small and often use unique fishing methods developed to suit local conditions. (D.Pi.)

HARBOURS AND PORT MARKETS

The purpose of a fishing harbour is to provide safety for boats, to transfer the fish rapidly to the market or consumer, and to speed the vessels' landing, maintenance, and departure. Facilities for unloading, sorting, and weighing, market halls, merchants' buildings, ice plants, refrigerated storage, and processing plants may be needed depending upon the type of fish product being handled. For vessel repair, a shipyard or slipway is necessary, with engine and electronics shops, net loft, chandlers, and victualers. Fuel may be supplied from floating or shoreside stations, and fresh water is needed for drinking, cleaning, and processing. Electric power, road and rail access, and good communications facilities are important, together with waste disposal arrangements to prevent harbour pollution.

In its simplest form, a fishing harbour may be a stretch of open beach or a landing site in a rocky coastline, from which canoes or small boats are launched and retrieved manually or with a simple winch. The catch may be sold directly to consumers from the boat or to middlemen who distribute the fish within a wider area. Facilities may include simple storage sheds for nets, outboard motors, fuel, and other supplies. A much more expensive alternative is a pier constructed beyond the surf zone, where boats are lifted out of the water by crane and stored on the deck.

Natural and man-made harbours

Larger, heavier boats with inboard engines require sheltered anchorages or moorings, since they must remain afloat. In sheltered coves or inlets a simple rock jetty or wood wharf may be sufficient, with storage, fish handling, and service facilities nearby. If a sheltered site is not available or has insufficient water depth or area, it is necessary to construct protective breakwaters to form an artificial harbour within which the necessary quays, slipways, support, and fish-handling facilities are built.

Larger harbours serving many bigger vessels may be planned and built by government bodies that operate the facility themselves or lease it to a port authority or company. Often, service facilities such as net lofts, slipways, engine and electronics dealers, and supply stores are provided by small entrepreneurs or private companies.

Fish-handling and processing facilities may include individual stalls selling fresh fish, auction halls where wholesalers purchase their supplies, or processing plants with freezing facilities producing sophisticated consumer packs from raw fish landed at the docks.

Most harbours are communal in use, serving a wide range of vessel owners, merchants, and processors. However, large companies with considerable fleets often construct private integrated facilities that include processing, maintenance, and service operations. This is especially the case in developing countries, where only small-scale landing facilities may exist. (J.C.Sa.)

Types of fishery

SALT WATER

Fishing in salt water ranges from small, traditional operations involving one person and a rowboat to huge private or government enterprises with large fleets for deep-sea and distant fisheries.

The Law of the Sea

The Law of the Sea extended from 12 to 200 miles an exclusive economic zone (EEZ) within which a coastal country has control over fisheries and their exploitation. This effectively restricts most fishing operations on the continental shelves to national vessels or to craft licensed by that country. Within the EEZ, fresh water and coastal waters are often demarcated by law, with fishing within, for example, three miles of the coast allocated only to small-scale, non-trawling fishermen and larger industrial vessels required to remain farther offshore. Small-scale fishermen are usually not restricted to the three-mile zone, and they often may be found well offshore or along the coast from their home ports as they follow the fish. For example, West African canoe fishermen traditionally migrate hundreds of miles coastwise in open canoes, frequently fishing out of sight of land. (A.v.B./J.C.Sa.)

The oceans. The oceans constitute the largest factories of living organic matter on Earth, in both magnitude and total productive biomass. Average organic production per acre is identical to that on land, although productivity varies greatly from one area to another, ranging from luxuriance to almost barren deserts. Production in any specific area varies with the seasons and is subject to large and sporadic fluctuations.

The primary production area of the oceans is the photic zone, the relatively thin surface layer, 25 fathoms (50 metres) deep, that can be penetrated by light, allowing the process of photosynthesis, the use of energy derived from sunlight in the manufacture of food, to take place. All marine life is directly or indirectly tied to the photic zone, on which both recycling and decomposition, also in other spheres of the ocean, depend. Those few microorganisms deriving their energy from sources other than light have relatively little significance in the overall productive balance of the oceans.

In the photic zone, growth rate depends on light intensity and available nutrients. Nutrients are constantly depleted by the slow sinking toward the bottom of dead plankton, the floating and mainly miniature plant and animal life, which forms the primary link in the ocean food chain. Simultaneously, fertility is constantly restored as the nutrient-rich deeper waters are brought to the surface. The ocean is ploughed by the action of winds drifting surface waters away from coastal areas, by nutrient-rich waters welling up from the depths, and during the winter season of the temperate regions by cooled surface waters becoming heavier and sinking downward, forcing nutrient-rich waters to rise.

As a rule tropical surface waters do not interchange with the mineral-supplying waters below as much as those of colder regions and are therefore less productive. However, under certain conditions in some regions of the tropics and subtropics, currents and winds induce a sustained upwelling of mineral nutrition from lower strata, producing spectacular results. Such regions include the waters around the west coasts of southern Africa and South America. Consideration of such conditions demonstrates that the production of fish-supporting plankton is not related to latitude but depends upon the presence of "new water" high in nutrient salts.

Food chains

The marine food chains, ranging from minute floating phytoplankton, sometimes called the "grass" of the sea, to the large predatory species, have many more links than terrestrial equivalents. Each transfer of food value from a lower to a higher level involves a considerable loss in the amount of recoverable organic matter, and consequently of food, so that the amount of organic matter is much greater at the plankton level than it is in fishes. The daily production of dry organic matter in kilograms per square metre beneath the surface of the English Channel is as follows: phytoplankton (plant life) 4–5; zooplankton (animal life) 1.5; pelagic fish (living near the surface) 0.0016; bottom fish 0.0010.

The plankton eaters, although they tend generally to be small in size, include the basking and whale sharks, the largest of all fishes. Typical consumers of marine plankton include such species as herring, menhaden, sardines, and pilchards. Because of this plentiful food source, these fish exist in tremendous numbers, forming the basis of important fisheries.

Demersal fishes, including such species as haddock and halibut, live primarily near the ocean floor, where they feed on various invertebrate marine animals. Most of the large fish, such as tuna, swordfish, and salmon, feed on smaller fishes.

Objects of sea fishery. *Fishes.* Small, schooling pelagic species are the most abundant fish in the near surface waters of the seas. Pilchards, capelin, herring, sardines, anchovies, menhaden, and small mackerels make up more than one-quarter of all saltwater landings. These fishes travel in immense schools several miles long and wide, containing thousands of millions of individuals. Herring feed on small marine animals and other plankton; in turn, such predators as cod, mackerel, tuna, and sharks, as well as certain kinds of whales and birds, eat freely from the enormous schools. Actual landings of each species tend to follow cycles as a result of fluctuations in the size of the resources owing to natural environmental changes and fishing pressures. Most of the catch is directed to production of fish meal and oil.

The codfishes, including cod, hake, haddock, whiting, pollock, and saithe, share with herring the leading place among edible marine fish. Alaska pollock is the most important, particularly for Russia and Japan. Atlantic cod is an important food fish in both Europe and North America.

Salmon are anadromous, migrating to ocean waters for growth and returning to fresh water for spawning. Pacific salmon return to the freshwater rivers once, to spawn and die; the Atlantic salmon make several returns. Industrial pollution, silting, and damming of rivers for hydroelectric power have seriously threatened the salmon. Only through such large-scale management measures as bypass streams and hatcheries has it been possible to save the Pacific salmon; similar measures with respect to the Atlantic salmon have been less successful.

Flatfish include a great many species, such as plaice, halibut, and sole, living largely at the bottom of the coastal shelves. The stock of each species is quite limited, however, and halibut was one of the first species for which catch quotas were established.

A major change in ocean fishery since World War II is the intense exploitation of redfish, also called ocean perch. Jack mackerel, one of the earliest fishes used for human food, continues as an important food source. Although it lives in midocean, the catch has increased.

Tuna

The true tuna fishes include albacore, bluefin, bigeye, yellowfin tuna, bonito, and skipjack. These species represent a significant marine source of human food, hunted since ancient days. Both Atlantic and Pacific stocks have been heavily fished since the end of World War II, and signs of excessive harvest have appeared. More than half the global catch is canned or frozen for the U.S. market. Spanish mackerels and swordfish belong in this group but, despite efforts toward increasing the catches, both remain minor items.

There are some 250 species of shark. Like the whale, sharks have a broad range of feeding habits. Although many are predators, some, including two of the largest fishes in the oceans, the basking shark of the northern temperate zone and the whale shark of tropical waters, are plankton feeders. Shark meat is commonly eaten in warm latitudes but elsewhere is little esteemed, except for the fins, high in protein and considered a delicacy, which are frequently used in soups.

Since World War II, many new fish species have been exploited. The clearest indication of this is the doubling of the catches of nonidentified fishes, a category that equals the volume of codfishes.

Shellfish. The term shellfish is generally applied to all invertebrate marine organisms having visible shells. They may be broadly categorized as crustaceans and mollusks.

The crustaceans include lobsters, crabs, crayfish, and both shrimp and the closely related but larger prawns. The shells consist mainly of a hard, inedible substance called chitin. Crustaceans molt frequently during growth. Blue crabs are eaten when molting and soft-shelled. Marine lobsters are eaten when about five years old and have by then molted about 25 times.

The shrimp industry

With the development of satisfactory freezing techniques in the 1940s, shrimping expanded considerably, becoming a global operation. The United States is a major consumer, importing shrimp, mainly frozen, from more than 60 countries. South Africa and Australia have developed a worldwide market for rock lobster, and Japan and Russia dominate the world market for king crab.

The major mollusks consumed as food are oysters, mussels, clams, scallops, whelks, and snails. The best-known marine snail is the abalone, encountered in many warm waters. This group also includes the octopus, squid, and cuttlefish, popular seafoods in Mediterranean countries and the Far East.

Sea cucumbers (holothurians), or sea slugs, are usually marketed under the name of trepang or bêche-de-mer. Rich in protein, they are eaten in China, Southeast Asia, Australia, and Italy.

Mammals. Ocean mammals include such cetaceans as whales, porpoises, and dolphins, as well as seals and walruses. Whales are a source of meat, fats, and oils, hormones such as insulin, and chemicals. They exist at all levels of ocean food chains. The blue whale mainly devours small reddish shrimp called krill, while the formidable killer whale feeds on salmon, seals, and sharks. The number of species, although still large, has declined considerably. See the section *Whaling* below.

The hunting of porpoises and dolphins preceded whaling in history. Dolphins were eaten in ancient times around the Mediterranean, and Xenophon and his Greek army found sizable stores of salted dolphin meat in earthenware vessels on the Black Sea coast. Their use as food there continued until banned by the Soviet Union in the interest of preserving the animals for biologic research. Many tropical islanders still hunt dolphin on a large scale. Freshwater dolphins are caught in many of the world's great rivers, including the Ganges, Indus, and Brahmaputra, the Amazon, and the Río de la Plata. The dolphins of Chinese rivers have been eradicated, but a number survive in the lake regions of the upper Yangtze.

Seaweeds and plankton. Marine plants may be divided into two groups: grasses and algae. There is only one subaquatic grass of any significance, namely eelgrass. Algae that grow in a fixed location, generally called seaweeds, may be categorized according to colour, into green, brown, red, or blue-green. Brown algae, sometimes called kelp, may grow to exceptional sizes; some specimens attain a length of 50 metres or more.

Seaweeds are heavily exploited in many parts of the globe for human as well as animal food. Several species are extensively cultivated on the coastal shelves of China, Japan, the Philippines, and elsewhere. Brown species in particular are harvested in Japan and made into a number of food products. Several are used as material for various thickening agents.

Cultivated red seaweeds belong to the genus *Porphyra.* Their sun-dried, blackish fronds are shaped into sheets and used in the Orient as a wrapping for rice. Harvested along the coasts of Ireland and Scotland, red seaweed is made into a powder and used as the main ingredient of a kind of bread called laver. Seaweeds contribute to the diet accessory nutrients such as vitamins B_6 and B_{12}.

Phyto-
plankton
as food

Phytoplankton does not offer man a suitable food and can hardly be used even as feed for animals. Many species are toxic; the rest are scarcely digestible. In addition, most plankton finish their life cycle within a few days or weeks and are usually devoured by predators. Consequently, the amount of plankton in the water at any given moment is small, even though total plankton production over a year may, in a particular water, well exceed that of fish. Plankton harvesting is therefore very difficult, because of the volume of water that must be sieved, but several attempts to develop a feasible harvesting device have been undertaken. The Japanese, Burmese, and East Indians have managed to develop profitable fisheries for certain tiny shrimp that feed on plankton. The shrimp are dried or fermented into pastes. Elsewhere similar plankton-fed shrimp are sun dried and sold as a snack.

Unicellular green algae, such as *Chlorella* and *Scenedesmus,* have been artificially cultivated, yielding 75 tons per hectare (30 tons per acre) per year, compared with the standard wheat yield of 2.5 to 3.7 tons. However, the process is costly, since algae, in addition to harvesting, require decolorization and special processing to remove or break down the cell walls through drying and enzyme action in order to become digestible. It is far more efficient to use such plankton directly as fish feed in cultivation ponds or in the raising of cattle and poultry. Blue-green algae easily create waterblooms, slimy accumulations that may be dried in the sun and molded into small loaves with a nutlike flavour and high in protein. This food is extracted from Lake Chad in tropical Africa, and the Aztecs made a similar product. In China a scum called *lan,* collected from ponds and freshwater lakes, provides sustenance for large numbers of people. A related scum, *keklap,* found in Java, is used chiefly as fish feed. Another species is made into dried sheets in Japan and prepared for food by heating in water. Successful cultivation of some blue-green species has been carried through on a semicommercial scale. (G.A.B./J.C.Sa.)

Spotting
pelagic fish

Fish finding. Traditionally, sea fishermen have known the time and place to find their catch, but the history of fishing has demonstrated more than once that even old and rich fishing places can become exhausted quite suddenly. This is especially true with pelagic fish like herring, pilchards, or sardines. The herring yields of the Schonen fishery and later on of the Bohuslaine fishery (1744–1809) in the Baltic Sea fell so severely that the very existence of the Hanseatic League was compromised. This sudden change did not result from overfishing but was caused instead by natural fluctuations in the development of stocks. In modern times, sardine fishing collapsed off the California coast in 1952, followed by the Peruvian anchovy fishery 20 years later. Similar disasters have occurred in other parts of the world not only because of overfishing but also for natural reasons. When this happens new fishing places must be found. It is difficult to explain how good fishing places in great depths were found in ancient times, but fish in shallow waters, fjords, or small bays can easily be seen. On the high seas, fish can be located when they surface temporarily, and fish searching by direct observation from a vessel is important even today. Airplanes and helicopters are commonly used in purse seine fishing. An experienced air-spotting pilot can detect fish under the surface and identify species by observing the shoal's form or colour or behaviour and sometimes by the presence of accompanying birds. During the night, fishes can be located through the phenomenon of bioluminescence; *i.e.,* when their passage through the water causes tiny marine organisms to luminesce. Accompanying birds have played an important part in fish searching for centuries, because a concentration of birds can be seen from a distance. Very often the birds are not attracted by the fish sought but by smaller fishes and squid, which may have taken refuge from large species by swimming to the surface. Other animals may also indicate fish concentrations by their presence. Porpoises, for example, are known companions of tuna, and tuna purse seiners often set their nets where porpoises have been seen. To find fish in deeper waters by other means was difficult if not impossible in the past. Herring fishermen used signal lines to find their prey in deep waters. These were long wires dropped from a boat; the fisherman holding the line in his hand could feel the vibration caused by the fish touching the line, which was named the herring's telephone. Other fish were also found by signal lines, often tied with fishing gear. In modern industrial fisheries, experiments have been made with direct listening for fish, but this method has been found impractical. Sea fishermen have also learned to judge where fish can be expected by observing environmental conditions. The colour of the water and the presence of current or of a borderline between different water bodies are some common fish indicators. One of the most important physical properties for fish finding is the temperature of the water. The use of thermometers was one of the first practices fishermen learned from oceanographers, not only for fish finding but also for forecasting availability of the desired species. Aerial and satellite surveys of these properties are becoming of increasing importance.

Echo
sounding
and sonar

The first experiments using electrically generated sound pulses and their echoes to locate fish were undertaken in Britain during the 1930s, and by the 1950s fish-finding echo sounders had become an essential aid to catching. As these units worked vertically, they only showed fish immediately below the vessel, so that a logical development was the application of sonar in order to search horizontally around the boat. For many years the machines provided only a "black on white" paper display of the resulting echoes, and interpretation of the displays was dependent upon the skill of the skipper. Gradually, improvements were made in the quality and quantity of information displayed, enabling monochrome signals to be displayed on a television-type screen. A big breakthrough came with the advent of microprocessor technology, which made it possible for fish-finding sonars and sounders to rapidly analyze the signals that their high performance transducers picked up from the sea. Information regarding size, abundance, and movement of the fish is now displayed in many colours, provides the skipper with a wide range of scales, and enables him to focus on and expand information at a particular depth or location.

Other instruments have become vital to fishing operations, especially radio- and satellite-transmitted position-fixing equipment such as Decca Navigator, Loran, and Satnav. These enable a skipper to return to the precise position where fish are spotted or to a particular location such as a coral reef or where gear has been set. Microprocessor technology allows information from various instruments such as sonar, radar, Satnav, and Loran to be fed into a single television screen that provides the skipper with information processed to suit his needs. The vessel's movements, shown on the screen, can be integrated with navigation and fishing charts fed into the display from computer memory banks. By linking these instruments to the control of winches, engines, and rudder, fully computerized fishing operations are possible.

Sea-fishing methods. *Pole-and-line fishing.* Line fishing at sea is very popular, not only in traditional fisheries with small boats employing a limited number of hooks but also in industrial operations with large vessels or fleets using thousands of hooks.

Pole-and-line methods are used in tropical Pacific and Atlantic waters to catch young bluefin and yellowfin tuna, and smaller tuna species—such as albacore, skipjack, bonito, and little tunny. The pole, generally bamboo, ranges in length from two to 10 metres, with a line of roughly the same length. Hooks of various sizes are barbless to facilitate baiting and removing the captured fish. To hold onto the pole a "rod rest" is generally used, which is made of canvas, leather, or old rubber tires. Depending on the size of the vessel, the crew may number 30 or more. A large crew is needed, since fishing time may be limited and the maximum possible number of rods must be worked. If larger and heavier fishes are sought, two, three, or even four poles may be linked to a single hook. In this case the fishermen must cooperate closely. Also used successfully are deck- and rail-mounted automated fishing poles operated hydraulically and electrically. The fibreglass rods are mechanically moved up and down, swinging the hooked fish onto the deck and removing the hook before swinging it, unbaited, back overboard.

Automated tuna fishing

Automated pole-and-line gear on a Japanese tuna vessel. One man can work as many as eight rods.

The tuna is attracted and kept near the vessel by chumming, throwing live bait overboard. The bait is kept alive on board in special tanks in which seawater circulates constantly. Bait can be an expensive problem for tuna fishermen; to catch one ton of tuna, roughly 100 kilograms of live bait fish are needed. Sometimes the hooks are baited, sometimes artificial lures are used with hooks hidden in feathers. When the tuna is "hot" (very eager to take the bait), a naked hook is sufficient. Water spraying helps to attract the tuna; it also serves to camouflage the shadows of boat and crew.

Pole-and-line fishing for tuna is done in daytime from slow-moving vessels. Since considerable space is needed for the angling crew to stand side by side on the lee side of the vessel, Japanese vessels for pole-and-line fishing have a long extended bow. To simplify hauling in the catch these boats also have a low freeboard (*i.e.,* their sides ride low above the water). American tuna vessels hang special crew racks outside the ship over the water.

Drifting longlines. Used for tuna—especially in Japan, Taiwan, and Korea and to a limited extent in South Africa, Cuba, and Oceania—drifting longlines are particularly successful in the tropical Atlantic for big fish in depths from 60 to 250 metres. More than half the fish caught in this manner are yellowfin tuna, one-third are albacores, and the remainder bigeye and bluefin tuna. Sharks, marlins, swordfish, and sailfish, also caught with drifting longlines, are sometimes included in the tuna statistics. Sharks can cause serious losses by attacking hooked tuna. Originally longlining for tuna was a Japanese inshore fishery. At the end of the 19th century, the Japanese were fishing 50 to 65 kilometres off their coasts. This fishery was extended when sailing boats were replaced by motorized craft, and by 1926 the Japanese began longlining for tuna off Taiwan, by 1929 in the Indian Ocean, by 1930 in the South Pacific, by 1938 in the eastern Pacific, by 1952 off the southeastern coast of Australia, and since 1955 in the Atlantic. A longlining crew must be willing to do a hard, though lucrative, job and remain far from home for long periods. The gear is a line composed of 400 to 450 sections, each section with a length of 150 to 400 metres stored in a basket. The total line can have a stretched length of up to 180 kilometres. Each section is composed of subsections of different length. The branch lines with the hooks are composed of three sections that vary in number and length. From one to 12 (generally five) branch lines with hooks form one section; 2,000 hooks are considered the greatest number that can be operated in one set by a vessel. With decreasing catches, attempts have been made to increase the number of hooks; Korean fishermen are said to operate as many as 3,000. The shooting of the line from the stern of the vessel begins early in the morning before sunrise, when the vessel is moving at a speed of about five knots (five nautical miles per hour) or more. During shooting the lines have been tied together and the hooks are baited with frozen Japanese sauries. Each section is tied with a float line and a buoy. Depth of the gear can be regulated by the length of the float lines and the distance of the floats. Ten to 14 men require four hours to perform the task. Hauling from the forepart of the vessel begins in the early afternoon with the help of a line hauler. Depending on the quantity of the catch, hauling can take more than 10 hours with a crew of eight to 10. With preparing and sorting the catch, the usual working day of a crew member totals some 18 hours. Because of this and the fact that vessels stay at sea more than 200 days per year, the Japanese and Taiwanese have experienced difficulty in procuring crews; this problem has led to the development of new technology to simplify the work and reduce manpower. One such improvement is the reel system, made especially for larger vessels. The total line is set, hauled, and stored on a drum, and the floats and branch lines are stowed on separate reels and clipped on or removed as the main line is set or hauled. Research is being done on a coupling apparatus to do this automatically. Another invention is a line-winder system practicable for small vessels. In this a single line is used, hauled and coiled by a line winder in special tanks in the aft part of the vessel.

Labour-saving technology

Bottom longlines. For centuries, line fishing for demersal fishes was carried on in coastal waters and far at sea in the dory fishery famous today. A sailing mother ship carried the dories from Portugal, France, Canada, and the United States to the Grand Banks for cod. The one-man dory operated near the carrier setting longlines and sometimes fishing with handlines. In the evening the catch was carried back to the mother ship where each man prepared his catch for salting. Some large-scale modern enterprises also fish with bottom longlines, catching many species of the cod family, including cod, haddock, coral fish, hake, and pollock, as well as rays, and many flatfish, such as halibut. There are also longline fisheries for groupers, hairtails, croakers, and sea breams. Bottom lines are not as long as the more easily controlled drift lines. The hooks do not always lie on the bottom but may hang above it to protect the bait against unwanted bottom predators, such as starfish, snails, or crabs. Typically, bottom lines are used for halibut in the northern Pacific. A relatively heavy main line is divided into sections of approximately 90 metres. The branch lines, each about 1.5 metres long, are tied at intervals of four to 5.5 metres. Modern synthetics, with their greater strength and lighter weight, have replaced natural fibres for main lines. Fishing depth usually ranges between 80 and 270 metres, depending on the grounds and season. The setline is anchored on both ends, marked by a floating keg and a lighted flag buoy at night.

An automated longline system developed in Norway baits hooks when setting, then cleans and stows them on magazine racks when hauling. This, and a number of similar systems, has enabled more hooks to be set by smaller crews and has thereby revolutionized the bottom longline fisheries of Europe and North America.

Traps. There are only a few areas in the world where water or weather conditions prohibit the use of traps. A single small vessel can operate hundreds of traps, though lack of storage space may cause difficulties. Thus collapsible traps of netting on a wire framework are often preferred not only for fish but also for crustaceans. Many plastic traps are made, especially for lobster. Some can be dismantled for easy transportation. Water snails, such as whelk in England and other species in Korea, are also trapped, as are cuttlefish and octopuses. As in fresh water, fyke nets can be set in long rows or in connected systems.

Setting traps

Commercial sea fisheries set long rows of pots or framework traps by the longline system; *i.e.,* single pots are tied with a branch line to a main line. Hauling is accomplished with small hand-operated or motor-driven winches. More important for catching fish in commercial sea fisheries are the big wooden corrals, or weirs, and the large pound nets. The oldest type may be the Italian tonnara, used in the Mediterranean for tuna from the Bosporus to the Atlantic. Very large pound nets are also used by the Japanese on the Pacific coast, by the Danes and their neighbours off the eastern coasts of the Baltic, and for salmon fishing off the Pacific and Atlantic coasts of North America. The difficulty in setting large traps lies in placing them on the bottom. If the water is not deep and the bottom is not hard, the weirs can be held by sticks or piles. Where the water is deeper and the ground is hard or rocky, the weirs must be anchored.

Dragged gear. Dredges and trawls are of great importance in commercial sea fisheries. Dredges are generally used in shallow water by small vessels, although a deep-sea dredge is operated by research vessels at depths of up to 1,000 metres. The simplest dredges in sea fishery are hand operated. Fitted with a stick up to five metres long, they resemble rakes combined with a bag for collecting the catch—usually mollusks or crustaceans. Heavier dredges with a triangular or quadrangular iron frame may be towed along the seafloor by small vessels or pulled some distance from the shore or from an anchored vessel and then towed back with a winch. For digging out mollusks, some dredges have iron teeth on the lower edge of the frame. They may also have a pressure plate on the upper part and chains on the lower part, depending on the catch sought. The bag of the dredge is made of wire rings that have good resistance to friction and of hard fibre netting. Usually more than one dredge is operated by a vessel, and they are towed with the help of outriggers. The great disadvantage of dredging is that much of the catch is damaged, wasting effort and needlessly killing fish.

Trawling

Trawling in sea fishery can be done by small vessels or even rowboats (as in the estuary of the Tagus River near Lisbon). More important, however, are fleets of highly mechanized trawlers whose gross registered tonnage may reach 5,000 and whose horsepower approaches 6,000. The trawl is a towed net bag with a wide opening at the mouth and an end closed by a special knot. The mesh size of the opening can be large—600 millimetres (two feet) from knot to knot—to diminish water resistance during towing. The closed end (called the cod end) can have meshes of six millimetres, depending upon the species of fish or shrimp sought. The trawl is designed in a smooth funnellike shape to guide the fish into the cod end. To keep the mouth of the trawl open, a large horizontal beam may be used. The beam can measure up to 12 metres in length and is based on two guides that glide over the bottom. The Dutch catch flatfish with beam trawls that have heavy chains, called tickler chains, dragging on the seafloor in front of the net opening between the two gliders to frighten the fish from the bottom into the trawl. Additional stimulus is often provided by electrifying the tickler chains.

Though beam trawls were the original gear of deep-sea steam trawlers, today they are used by smaller vessels only. Beam trawls are usually towed in pairs, one on each side of the vessel. Such an arrangement can considerably decrease the stability of the vessel and is dangerous except in craft specially designed for the purpose. Another method involves two vessels stretching the horizontal opening of the trawl between them. Two vessels have more power to tow a bigger trawl at greater speed, but the skippers of the two vessels must cooperate very closely. The most important method for spreading a trawl opening employs

two trawl doors, or otter boards, rectangular or oval plates that are attached to each side of the net and caused to flare apart by the pressure of the water.

Mid-water trawling involves dragging the trawl with one or two vessels in the area between the ocean bottom and its surface to catch pelagic fish. The trawl is set at the depth where fish have been observed by varying the length of the towing warps and the speed of the towing vessel. With longer warps and lower speed, the trawl sinks; it rises with shorter warps and higher speed. The depth of the trawl is monitored by a special transducer called a netsonde, which is mounted on the trawl and transmits echograms showing the position of the net in relation to the bottom and to the school of fish.

The netsonde

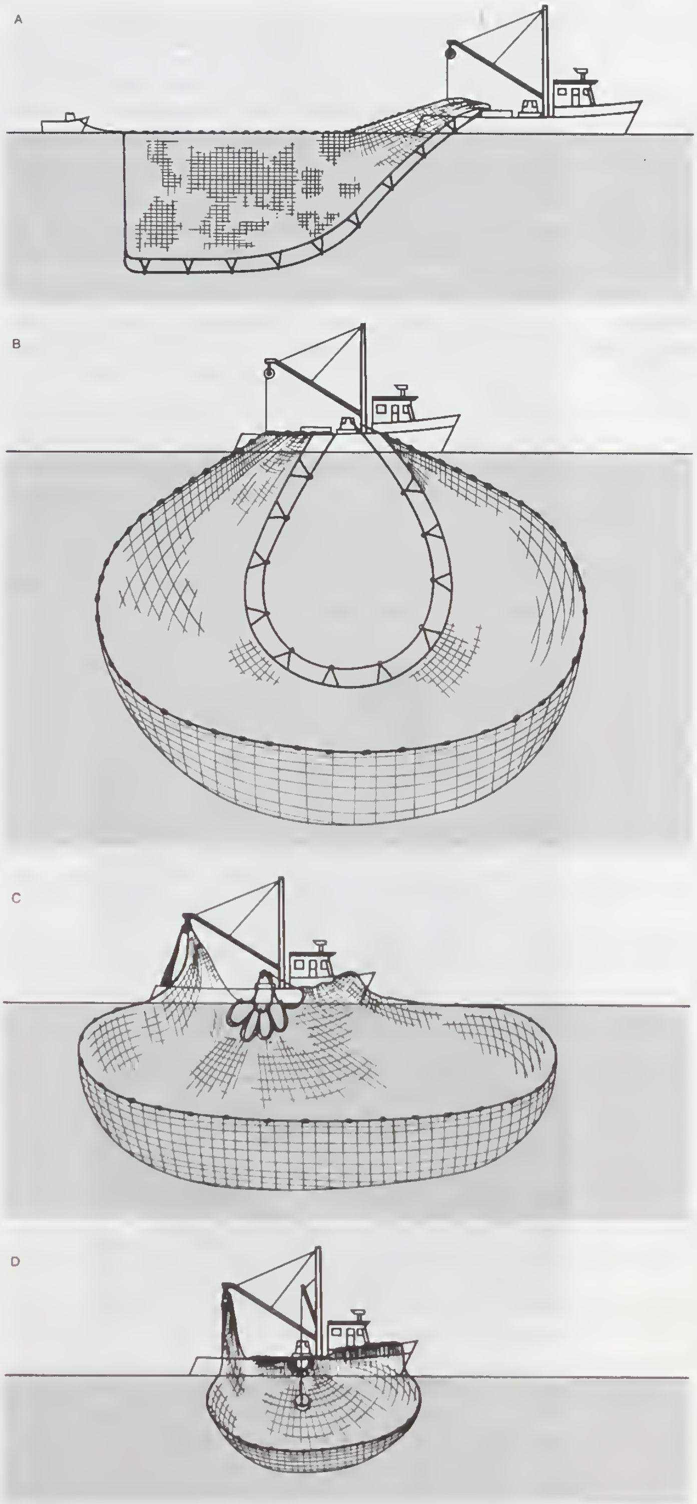
A special type of mid-water trawl is the semipelagic trawl, originally invented in Iceland and now operated primarily by French fishermen. In this technique the otter boards remain in touch with the bottom but the trawl floats at some distance above it. Semipelagic trawls were constructed because fish often are concentrated at a short distance from the bottom outside the range of the usual bottom trawl, which has a low, wide opening. To overcome this difficulty, a higher opening of the trawl is needed. Though the opening of a bottom trawl can be stretched vertically by various means, such stretching decreases the horizontal width of opening. Some modern bottom trawls are constructed with a high vertical and horizontal opening, and many consider them the best available gear for bottom trawling.

Seine nets. Seine nets are often employed in beach seining, where fish shoals are near beaches. Large beach-seining operations for sardinelike fishes and other species are carried on in the Indian Ocean. The importance of this method has decreased as pollution has cut the available stocks of fish in this region and as manpower costs have risen: not all fishing methods lend themselves to mechanization. More successful are anchor seines, better known (because of their origin in Denmark in 1849) as Danish seines. The gear consists of a net similar to a trawl but with a large bag and long wings connected to long towing ropes. One of the ropes (up to 1,000 metres long) is tied to an anchored buoy. The other rope is tied to the vessel, which steams in a wide circle, laying the ropes and returning to the buoy. The ropes act to keep the net open and herd the fish toward the bag. The vessel then hauls both ropes together until the net bag is taken on board. This method is used in northern Europe for flatfish and cod and in Japan has become the most important method of inshore fishery for bottom fish, after two-boat trawling.

Purse seines and lamparas. The most important sea-fishing gear is the surrounding net, represented by the older lampara nets and the more modern purse seines. Both are typical gear for pelagic fish schooling in large and dense shoals. When these nets are used, a shoal of fish is first surrounded with a curtain or wall of netting that is buoyed at the surface and weighted at the bottom. The lampara net has a large central bunt, or bagging portion, and short wings. The buoyed float line is longer than the weighted lead line, so that, as the lines are hauled, the wings of the net come together at the bottom first, trapping the fish. As the net is brought in, the school of fish is worked into the bunt and captured. With the purse seine, once the school is surrounded, the bottom of the net is closed by drawing a line through rings attached to the lead line. This pulls the net shut at the bottom like a purse, and when the net is hauled in, the concentrated fish are removed by a brail (dip net) or are pumped aboard the fishing vessel.

Hauling a purse seine

Surrounding nets are used for tuna, herring, sardines and related species, salmon, mackerels, and even cod (when they come to spawn in the pelagic zone). For these nets to be successful, the fish must be in large and dense shoals; light and bait are sometimes used as lures to produce such shoaling.



Setting and hauling a purse seine.
(A) Attaching one end of the seine net to the skiff, the seiner steams around a school of fish while laying the net. (B) Seiner hauls in purse lines, drawing shut (pursing) the bottom of the net. (C) Seiner hauls float lines, drawing in the web of net. (D) Fish are concentrated alongside, where they can be pumped or brailed aboard.

After J C Sainsbury, *Commercial Fishing Methods, An Introduction to Vessels and Gear*, (1971); Fishing News Books Ltd

Lift nets. Fish can also be caught, in limited quantities, by lift nets: stationary types operated along the shoreline, movable ones from rafts and boats, and large blanket nets held on each corner by a small boat. The Soviets operate a large commercial lift-net fishery on the Caspian Sea to catch sardinelike fish attracted by light. Each vessel operates two conical nets, setting one while the other is being lifted. Another effective lift net is the large, boxlike *basnig* of the Philippines, operated with a luring light during the night beneath a single outrigged vessel; sardines, mackerels, hairtails, squid, and other pelagic prey are caught. The Japanese have a special kind of lift net for sauries; the fish, attracted by light, swim over the netting lowered into the water and are caught when the netting is hauled.

Gill nets and drift nets. Quite important in commercial sea fisheries, gill nets are sometimes operated in large sets thousands of metres long. These generally drift with the vessel or are set as anchored nets in long rows at or near the bottom of the sea. Gill nets are used for many pelagic fishes, such as herring, pilchards, sardines and related species, mackerels, croakers, salmon, and tuna. They also are used for many bottom fishes—cod, Alaska pollock, and others. For cod, Icelandic fishermen set up to 90 nets, each about 50 metres in length, in depths up to 180 metres.

Historic importance of drift nets

Drift nets are widely used to catch pelagic sea fishes. In northern Europe, before the introduction of trawling, drift nets were the most important method of deep-sea fishery. In the old herring fishery of northwestern Europe, drifters commonly set more than 100 nets, each about 30 metres in length. Thus a fleet of drift nets might measure three or even four kilometres. The nets are set in the late afternoon to catch the herring as they ascend in the evening from ocean bottom to higher water levels. During the night the vessel drifts with the nets like a buoy. Hauling, done by hand or with mechanical aids, begins at midnight and, when big catches are taken, can continue until late morning. The fish are shaken out of the meshes by hand or with shaking machines.

Hauling in a gill net loaded with salmon.

Entangling nets. Similarly operated are entangling nets, single or double walled, and three-walled trammel nets. These are used in sea fisheries for hake, shark, rays, salmon, sturgeons, halibut, plaice, shrimps, prawns, lobster, spiny lobster, king crabs, and turtles. Single-walled nets are used in the southern part of the Caspian Sea and in the Black Sea to catch sturgeons by entangling. Iranian fishermen set about 150 sturgeon nets in one row perpendicular to the shoreline. Setting requires much labour; between each two nets a line is tied, which is connected to a short wooden peg driven into the bottom. The Turkish Black Sea fishermen sometimes set sturgeon nets in another form. Two nets always form an angle open to the sea. The nets are held by sticks rammed into the bottom. Sturgeon nets are checked once or even twice each day, depending on weather. For this purpose an Iranian fisherman lies on the bow of his sailboat, towing the vessel along the float line of the net. The sturgeons are taken from the water by hand or with a gaff.

The most important sea fishery for crustaceans is the king crab fishery in the northern Pacific. For the Japanese, who use entangling nets, this is a very important distant fishery ranking with tuna and salmon fishing. Originally carried on close to shore, king crab fishing was extended in the northern Pacific after its beginnings in the 1870s. The old land stations for processing were replaced by floating factories that accompanied the fishing vessels. The entangling nets are set on the bottom, sometimes 200 nets with a total length of 10 kilometres in one row. Larger catching vessels set 1,200 to 1,300 nets a day, usually in parallel rows about 500 metres apart. Nets stay in the water from five to seven days and are hauled by small open vessels with motor-driven reels, which can take from 2,500 to 3,000 nets per day out of the water. When hauling, the floats and sinkers are untied and the entangled king crabs are taken from the netting. The catch and nets are then transported to the mother ship, where the catch is processed and the nets cleaned, an operation that may require 30 minutes per net. Large racks for drying and cleaning the entangling nets are characteristic of this type of vessel. A single fishing unit may own a permanent set of 15,000 to 30,000 nets.

Squid fishing

Harvesting machines. A relatively new type of fishing gear is the harvesting machine combined with a pump, used in the northern part of the Caspian Sea for sardinelike fish and for squid off the California coast. In both cases the prey is attracted by light. Squid fishing can be done near the surface, but in the Caspian the fish are sucked on board with pumps from depths as great as 110 metres. In pumping, the suction nozzle is moved up and down with attracting lamps. Once on board the fish or squid are strained from the water. The difficulty in fish pumping is to avoid damage to the catch. Only small objects can be pumped without injury.

Another type of harvesting machine is the hydraulic dredge, with pumps and conveyors. These dredges wash out deeply buried mussels with jets of water under high pressure. The Americans operate such hydraulic dredges to harvest soft clams, and the British use similar machines for cockles. Harvesting machines also are used to cut kelp off California. Giant kelp is harvested by cutting to a maximum depth of 1.2 metres below the surface of the water and is transferred by conveyor belt into the open hold of the vessel. (A.v.B./J.C.Sa.)

FRESH WATER

Freshwater fishing is carried out in lakes and rivers or streams and to a growing extent in natural and artificial ponds. In some tropical areas, swamps with shallow water, sometimes overgrown with vegetation, are important inland fisheries. Before efficient transportation and distribution of ocean fish was organized, fresh waters were the only resource available for fish and other aquatic products for the inland population. Their importance decreased with the growing bulk fisheries of the seas. Freshwater fish now compose only about 5 percent of the total catch of water products of the world.

Major freshwater species

General characteristics. Widely different freshwater species—feeding on bacteria or detritus, plants or plankton, or living as predators—are used for human consumption. Well-known species include trout and whitefish, carp and other cyprinids, catfish, murrals, and tilapias. The desirability of some anadromous fishes—those, such as salmon and sturgeon, that spawn in fresh water but live in the sea—and catadromous fishes—those, most notably the eel, that spawn in the sea but live in fresh water—has led to specialized fisheries in inland waters.

The kind and quantity of fish found in lakes and rivers vary greatly with the physical and chemical condition of the water. Limnologists, scientists who study conditions in fresh water, classify fresh waters by the quantity of oxygen and essential nutrient salts (nitrates, phosphates, and potash) they contain. Fishermen classify waters by the principal fish to be caught therein. Rivers, for example, are divided into different zones beginning with the source, which is often good trout water, and ending in the estuary, where many coastal varieties of ocean fish can be caught. In like manner, fishermen classify lakes by expected catch (*e.g.*, eels, tilapias, or crayfish).

The great variations in the productivity of inland waters are explained by differences in their physical and chemical properties. Though some rivers may produce as much as 200 kilograms per hectare (180 pounds per acre) each year and some lakes may yield 160 kilograms per hectare, the world average is about eight kilograms per hectare.

Pollution produced by chemical preparations applied for agricultural purposes has created serious problems for the world's freshwater fisheries; fish cultivation is increasingly restricted to man-made waters. Traditional freshwater fisheries still supply basic protein to China, Southeast Asia, and tropical Africa but have been seriously affected in the United Kingdom, continental Europe, Japan, Central Asia, and the United States.

Because of pollution, freshwater fishing in natural waters has declined in industrial countries, but pollution is not totally to blame. The rapid rise in angling as a leisure pastime has created competition for the available waters and the fish in them. Because angling interests can afford higher prices for the rights to available waters, angling is now virtually the only fishing for wild fish that takes place in natural waters in industrialized countries. Some fish species that are considered delicacies and attract high prices are exempt from this trend. Fishing for salmon, eels, and crayfish is still very active on a commercial basis. With these fisheries there are many traditional rights to fishing certain waters.

In nonindustrialized countries freshwater fishing has increased considerably, mainly under the influence of aid programs. Some of these programs have tried to introduce new and more efficient fishing methods, but the main improvement has been in mechanization of the fishing boats used and in improved methods of preserving and distributing the catch. On some of the larger inland lakes, freshwater fishing is still the primary occupation in the villages along the shore.

Fish farming for freshwater species is being introduced in developing countries to produce a valuable source of protein. Where natural waters are fished in developing countries, fish management techniques are being used to improve the catch and to prevent overfishing.

Methods. Many techniques are employed to catch fish in inland waters, some appropriate to lakes alone, some to rivers only, and some to both. Of the many methods employed worldwide, only a few are economical for large-scale operation. Commercial line fishing, which uses many hooked and baited branch lines tied to a single main line, is widely practiced. A simpler technique is handlining, in which single lines with baited hooks are tied to small sticks or trees along the shore or to special devices set along the side of a hole in ice. Handlining is used for deep fishing or for catching in rocky areas. Drifting lines with one or more hooks can also be used on lakes, though seldom in rivers. Lines may also be trolled (trailed) behind a moving boat. On some rivers in tropical and temperate areas, fish are caught by fouling with sharp-pointed hooks. The main difficulty in line fishing is to keep the lines clear and to obtain baits in needed quantity.

Passive and stationary fishing gear

Passive and stationary fishing gear is so important in many lakes and rivers that some fishermen specialize entirely in trapping. Since deep and rocky shores, however, do not favour the use of traps, these devices cannot be used in all areas. Fish seeking shelter may be caught in simple brushwood devices when the brushwood is lifted quickly. More important are traps, such as wooden baskets made of wickerwork or of split bamboo, with retarding devices such as funnels or valves at the entrance. Wooden baskets, generally used in rivers with strong currents, can be set according to the longline system in which the baskets are tied with branch lines on a main line lying across the bottom of the river. Such baskets are usually baited, with the bait sometimes held in small bags or boxes. Today, in river fisheries as in coastal sea fisheries, traps, especially those used for eels, are made of plastic.

A more modern type of trap is the bag-shaped fyke net, held open by hoops; linked together in long chains, these are used to catch eels in rivers. When equipped with wings and leaders, fyke nets are employed in lakes where there are sheltered places with abundant plant life. Hundreds of such nets can be combined into systems where it is not economical to build large traps.

Another fishing method important in freshwater fisheries employs small scoop nets or large net bags (stownets). Such gear is known on many European and Asian rivers. The net bag is fixed to the river bottom to catch migrating or drifting fish. Some human control may be necessary; sometimes a watchman lives on a vessel or raft next to the stownet or on a special platform. Though stownets are especially popular in European rivers for eel fishing, their importance is lessening owing to increased boat traffic and to pollution. Moreover, the gear can be too large to be moved easily. In Indonesia stownets up to 100 metres long and up to 40 metres across the mouth are used. Small scoop nets can be operated by hand and pushed or towed over the bottoms in shallow waters. Sometimes this is done by fishnetting parties, in which all the men of a village form a line across the river, with a scoop net in each hand. Sometimes the fisherman stands on a platform built on the side of the stream and simply scoops up fish as they pass; this is done by some African fishermen in Malaŵi and was done by American Indians on the Columbia River in Oregon.

Seining

One of the most common fishing methods in freshwater lakes and rivers is seining, which is done in temperate zones especially in autumn and winter when fish are concentrated in deeper parts of the lakes. Because part of the seine must be dragged over the lake bottom while it surrounds the fish, seining is practicable only where the lake bottom is smooth and where favourable areas (*i.e.*, with fish concentrated near the bottom) are known. In some lakes such areas have been known for a long time and may be named and marked on fishing maps. Seine nets in lake fisheries can be very large, with wings of 1,000 metres each. Since traditional seining required considerable labour, mechanization became desirable. A modern mechanized seine-net fishery requires only a small labour force. In northern countries seine nets are used under ice. For this purpose a number of ice holes are needed for guiding the towing warps with the net on the underside of the ice sheet. Here also manpower is saved by motorized towing and coiling lines and by drilling the holes in the ice with power drills. Some success has been achieved in increasing the efficiency of seine nets by electric light. Fish trying to evade the net can be caught by stunning, or eels lying in the mud during the cold season (generally a time when eel fishing is poor) can be attracted out of the mud by an electrical current. The disadvantage of all seine nets is that they are not selective; many undersized fish that should be preserved cannot escape.

On larger lakes, sea-fishing methods such as trawling and purse seining are used. Two or more fishing boats are usu-

Cary Wolinsky/Stock Boston

Catching sturgeon on the Volga River, Russia.

ally required to set a purse seine net, which can then be hauled in manually by people on the shore. Lift nets are often used in fresh water, not only to catch bait fish for line fishing but also to catch crayfish or other freshwater crabs. There are small hand-operated lift nets tightened by frames and larger ones lifted from a gallows or with one or two vessels. Unframed blanket nets are used in rivers in Italy, each corner held by a gallows placed on the banks.

Cover pots and cast nets

Cover pots and cast nets also have some importance in commercial freshwater fisheries. Cover pots are especially used in rice fields or shallow waters with rich vegetation. Cast nets are used more in clear waters in lakes and in rivers; considerable skill is required to cast these. In Russia shooting mechanisms are employed to cast larger nets. Much more important in freshwater fisheries, however, are gill nets. The mesh size of the net can be used to regulate the size of the fish caught; thus smaller, undesired species escape. Lake fishermen use mostly stationary gill nets, anchored near the bottom or floating. River fishermen use gill nets that drift with the current, with one side tied to the boat and the other to a drifting buoy. With entangling two-walled nets and trammel nets, yield can be increased by frightening the fish into the netting; this is accomplished by beating the water or throwing stones. (A.v.B./D.Pi.)

AQUACULTURE

Aquaculture is the propagation and husbandry of aquatic plants and animals for commercial, recreational, and scientific purposes. This includes production for supplying other aquaculture operations, for food and industrial products, for stocking sport fisheries, for producing aquatic bait animals, for fee fishing, for ornamental purposes, and for use by the pharmaceutical and chemical industries. These activities can occur both in natural waters and in artificial aquatic impoundments.

Aquaculture has been in existence since at least 500 BC. However, only in recent times has it assumed commercial importance, with world production more than doubling between 1970 and 1975. The rapid expansion of aquaculture has been to a large extent in the production of relatively high-priced species frequently consumed as a fresh product. Examples are shrimp, crayfish, prawns, trout, salmon, and oysters. However, also increasing is the production of catfish, carp, and tilapias, which are reared in extensive, low-energy systems. For example, catfish farming in the United States has more than quintupled its production since it began to grow in the 1960s.

The growth of world aquaculture has been stimulated by a number of factors, including population increases, dietary shifts, and advances in aquaculture technology. Limited ocean resources have also helped to create a growing role for aquaculture in helping to meet increasing demands for fish and shellfish.

First artificial fertilization

Farming and rearing in hatcheries. Fish farming as originally practiced involved capturing immature specimens and then raising them under optimal conditions in which they were well fed and protected from predators and competitors for light and space. It was not until 1733, however, that a German farmer successfully raised fish from eggs that he had artificially obtained and fertilized. Male and female trout were collected when ready for spawning. Eggs and sperm were pressed from their bodies and mixed together under favourable conditions. After the eggs hatched, the fish fry were taken to tanks or ponds for further cultivation. Methods have also been developed for artificial breeding of saltwater fish, and it now appears possible not only to rear sea animals but also to have the complete life cycle under hatchery control.

Carp. Carp raising, practiced worldwide, is a good example of advanced techniques. For the whole life cycle at least three different types of ponds are used in Europe. Special shallow and warm ponds with rich vegetation provide a good environment for spawning, a process that today is often aided by hormone injections. After spawning, the parent fish are separated from the eggs and taken to a second pond. The fry, which hatch after a few days, are transported to shallow, plankton-rich nursing ponds, where they remain until the fall of the year or the next spring. In tropical areas, such as India, carp spawned from wild fish can be collected by experts in natural waters. To collect eggs or fry from wild fish is disadvantageous, however, because the breeder cannot influence the breeding stocks in a desired direction. In Asia, the fry of common or golden carp are thus generally bred under culture conditions in hatcheries. Bigger ponds are needed for rearing the fish in the second year of life. There are large carp ponds in certain areas of central Europe, while in Asia common carp are often cultivated in rice fields, a practice called wetland cultivation. This method is increasingly jeopardized by sprays used to control pests and diseases and by toxic agents resulting from industrial development. For feeding carp in ponds, soybean meal, rice bran, and similar agricultural products are used. Concentrated food in the form of pellets has also been successfully introduced. During the winter season in the temperate zone, the carp are kept in deeper ponds with a dependable flow of water to protect them against freezing. In central Europe, carp are ready for the market after the third summer. In southern Europe, Hungary, and parts of the Balkan Peninsula, carp may be sold after the second summer. In tropical areas the fish grow faster. To accelerate growth, warm-water ponds now exist in the temperate zone, where an average harvest of 400 to 500 kilograms per hectare is normal in intensive cultivation. By scientific management and careful selection it is possible to obtain yields up to 3,500 kilograms per hectare for carp in warm-water ponds.

Cold-water aquaculture

Trout. Although trout was the first fish to be artificially fertilized, trout cultivation in Europe and North America is much younger than carp cultivation. Trout are cold-water fish and must have a constant supply of sufficient oxygen, making cultivation more difficult. Though trout ponds can be smaller than carp ponds, good year-round water circulation is essential. Trout farms are therefore often located in mountainous areas where plentiful pure water is available. The young fish are obtained exclusively by artificial fertilization; thus, hatchery buildings with low-temperature water and good filters are the centre of this type of pond fishery. There the eggs are kept under control during breeding in special small tanks. As soon as the hatched fry can swim and eat on their own, they are transplanted to rearing ponds for feeding.

Trout are carnivores; meat-packing by-products are used for feed. Such food may be released into the ponds at predetermined intervals by automatic dispensers. Though many authorities claim that trout should have as much natural foodstuff as possible and therefore should be raised in natural ponds only, in many countries rearing is done in concrete-lined ponds or concrete tanks, which are easy to keep clean and permit disinfectant application. The time necessary to rear fish and the yield per hectare depend on feeding. Some trout farms sell their fish not only fresh and frozen but also smoked and filleted.

For trout and salmon, a new system of fish cultivation has been introduced. Instead of ponds, enclosures of netting or other materials are placed in natural waters, such as lakes, and also in brackish waters. By this means, areas formerly of low value can be farmed intensively. Farming trout in brackish water or seawater was of especial interest. Since the period preceding World War II, trout and salmon farming in seawater has grown tremendously.

Many other fish are raised artificially by various methods. Among these are sturgeon, milkfish, mullet, tilapias, striped bass, redfish, sea bass, and catfish.

Other types of aquaculture. *Mollusks.* Other important objects of cultivation in many parts of the world are mollusks. Though few water snails are cultivated, bivalves, especially oysters, are quite important in Asia, Europe, and North America. For centuries French fishermen cultivated oysters by placing twigs in the water to which free-swimming oyster larvae could attach. In northern Europe, oysters have been cultivated on the ocean bottom, but low winter temperatures limit the extent of this activity. In the Mediterranean, the Romans are said to have been the first to farm oysters.

Oyster cultivation

Today, oysters are cultivated on the Pacific coast of North America, as well as on the southern Atlantic coast and the Gulf of Mexico. Australia, the Philippines, and South Africa also possess farms, and the

Japanese grow edible oysters from Hokkaido in the north to Kyushu in the south. Japanese farms are divided into two classes: some cultivate seed oysters only, while others raise them for food, especially for export. The Japanese cultivate oysters on the sea bottom (horizontally) and on sticks (vertically). To collect the larvae, which affix themselves to any firm object, such as an old shell or a stone, fishermen place various devices in the water. These may be bamboo sticks with shells attached or a rope with shells hanging from it; limed tiles and wooden plates have been used for the same purpose in Europe. Production is greatest in places with good shelter against rough seas, a tidal current to carry food to the larvae, adequate salinity, and optimum temperature.

After some growing time, the larvae are loosened and transported to other areas for maturation under the best conditions. While growing to marketable size, the oysters must be protected against predators, such as starfish and oyster drillers. As starfish damage cannot be completely avoided when growing oysters on the bottom, a vertical system of culture is preferred in many areas; the oysters hang in clusters or in baskets or are fixed on poles in sheltered bays. In an alternative system, the oysters remain in horizontal trays kept at some distance from the bottom. Though such tray-raised oysters are expensive, they generally survive better than those reared directly on the bottom.

Blue mussels are cultivated in Italy, Spain, France, The Netherlands, and near Germany in the North Sea and the Baltic. There, too, horizontal-bottom methods have been replaced by vertical culture. Originally, the young mussels, collected from wild stocks, were spread on controlled banks leased by a fisherman from the government. Their capacity to grow in very extensive and dense beds is highly advantageous. Before full-grown mussels are sent in sacks to the market, special purification methods are employed to wash out sand. Today vertical culture is practiced with sticks pushed into the ocean bottom or with lines hanging from rafts. Unfortunately, line cultures may be damaged in winter; thus, experiments have been made with polyethylene net bags and endless tubes of polypropylene netting. These bags must be strong enough to carry the mussels until harvesting.

Many other mollusks are cultivated, including soft clams and scallops. The Japanese even raise octopuses and squid. For bivalves, the problems are roughly the same as mentioned above: collecting the larvae; raising the young mussels under good conditions; protecting them against predators; harvesting the adults without injury; and sometimes cleaning for the market.

Among inedible bivalves, pearl oysters deserve mention. Pearl farming is one of the most famous industries of Japan, dating to 1893, when a Japanese first succeeded in cultivating pearls. Under the skin of an oyster, the pearl farmer inserts a pearl nucleus (a small spherical shell fragment wrapped in a piece of living oyster tissue). The treated oyster is placed in a culture cage on a floating raft; after some months or years, the cultured oyster produces a pearl. Japan's pearl production is still concentrated along the coast of Mie Prefecture, where it was developed.

Pearl oyster culture

Crustaceans. Crustaceans—mainly shrimps, crayfish, and prawns—are also cultivated. In traditional Japanese practice, immature shrimps are caught in coastal waters and transferred to ponds. Today, mostly in the United States and Japan, shrimps are cultivated by catching adult egg-bearing females. The presence of eggs can be detected by examining the ovaries, usually visible through the shell. The female shrimps are transferred to large seawater ponds adjacent to the sea or to tanks. After hatching, the shrimps are fed in indoor tanks with cultivated plankton. After 10 days they are brought to shallow ponds for further cultivation or for distribution to other farms.

Americans, Australians, and Europeans have shown interest in commercial lobster culture. Production methods are not yet economical, however. The animals take two to three years to reach market size, and they have a high mortality rate. Lobsters must molt in order to grow and are quite vulnerable during the molting period.

Seaweed. A final important item in aquaculture is seaweed. Laver, a red alga, is a traditional part of the Japanese diet. The Japanese first cultivated this plant in the late 17th century in the brackish water of Tokyo Bay. Originally, a vertical method was used, with bushes placed in the water. A horizontal method is now employed: large meshed netting made of rough materials is hung horizontally between poles at the proper depth. The algae grow there by themselves and the owners harvest them from the nets by hand. Harvesting begins early in November and continues until about March. After the season is over, the gear is removed and stored. Part-time fishermen or land farmers often engage in such algae culture. Though other algae are used for food and in industry today, commercial farming has yet to begin. (A.v.B./C.H.A.)

WHALING

International whaling developed in stages that were determined by changing demand, diminishing stocks, and advancing technology. A lengthy primitive stage eventually led to commercial whaling; new markets and technical and chemical advances produced modern whaling; and virtual extinction of the quarry led back to a final primitive stage. The commercial stages were overwhelmingly dominated by northern Europeans and Americans—first by the Dutch, then by the British and Americans, and finally by the Norwegians and British. Only at the very end, when the Europeans found the trade no longer profitable, did they surrender the remaining whales to the Japanese.

Primitive whaling. Archaeological evidence suggests that primitive whaling, by Inuit and others in the North Atlantic and North Pacific, was practiced by 3000 BC and has continued in remote cultures to the present. The primitive quarry were small, easily beached whales or larger specimens that came close to shore during seasonal migrations from polar feeding grounds to breed in sheltered bays. The Japanese used nets, and the Aleuts used poisoned spears. The Inuit successfully hunted large whales from skin boats, employing toggle-head harpoons attached by hide ropes to inflated sealskin floats. A number of harpoons were darted into a whale, impeding the creature's escape until it could be safely killed with a lance. In Europe, the Nordic people hunted small whales, and Icelandic laws dealt with whaling in the 13th century.

Early whaling from boats

The forerunners of commercial whaling were the Basques, who caught black right whales as the animals gathered to breed in the Bay of Biscay. Docile and slow moving, sleeping on the surface, the whales were chased by rowboat, struck by harpoon, "played" like fish, and then lanced to death. Their bodies, which floated after death, were towed to shore for the stripping and boiling of their thick blubber and the processing of their baleen. When seaworthy oceangoing ships were built, Basques set off in search of other whaling bays and found them—perhaps in the 14th century and certainly by the 16th—across the Atlantic in southern Labrador.

Early commercial whaling. While the Basques acquired experience, northern Europe developed more capital and better markets. Drafting Basque whalemen for its Arctic explorations, the English Muscovy Company initiated the exploitation of whaling bays in Spitsbergen in 1610. The Dutch followed immediately, and, with a combination of violence and better business organization, broke the English monopoly, which had already stifled native competition. Smeerenburg ("Blubbertown") was built on Spitsbergen after 1619; in its heyday in the 1630s and '40s, it had 150 men servicing whalers that hunted the Greenland right, or bowhead, whale in the neighbouring Arctic.

The demise of Arctic bay whaling owed less to overfishing than to a miniature ice age lasting for the rest of the 17th century. Smeerenburg shut down in the 1660s, and Dutch and German whalers navigated the open sea ice. Whales were flensed (stripped) alongside the vessels, and their blubber (preserved to some extent by the cold) was brought home in barrels. This Greenland phase of whaling—extending into Davis Strait after 1719—was dominated by the Dutch and Germans until their activity collapsed in the 1780s. At that point Britain, in order to service its industrial revolution, took over as the principal European whaling nation.

Sperm whaling

Since the 1690s the British had "fished" from bay stations in their North American colonies, with Cape Cod, Long Island, and Rhode Island becoming the centres of activity. There a new type of whaling was inaugurated in 1712, when a Nantucket vessel caught the first sperm whale, whose waxy oil and spermaceti were worth far more than right whale oil. The sperm whale was a free-ranging oceanic animal, encouraging expeditions into warmer waters, where rapid putrefaction of blubber occurred. Fortunately, sperm whales had far less blubber than did right whales, and in the 1760s try-works (brick ovens for rendering blubber) appeared on American vessels. Henceforth, voyages were limited only by the whaler's capacity and the whaleman's endurance. Whale hunts extended from the Atlantic to the rich grounds of the Pacific, where four-year cruises were not uncommon, often mixing sperm whaling on the open sea with sealing and bay whaling for right whales.

During the great age of early commercial whaling in the late 18th and early 19th centuries, the chief means of capturing whales were relatively light double-ended rowing boats. A crew of only six men put off in pursuit with hand harpoons and a coiled line to play the whale, which was killed with a hand lance when it was sufficiently exhausted. American boats were usually nine metres long and made of half-inch cedar, while the British boats in Davis Strait were stronger.

Both northern and southern commercial whaling entered the doldrums around 1860. The U.S. fleet of more than 700 vessels (with 429 registered in New Bedford alone in 1857) declined rapidly, owing to overfishing but principally to the discovery, in Pennsylvania in 1859, of petroleum, which replaced sperm oil in the lamps and candles of America. The Dutch fleet had collapsed early in the century. The British Arctic fleet was devastated in the 1830s and '40s by overfishing and ice and by the introduction of vegetable oil, steel-boned corsets, and gas-fired lamps. Residual activity continued in the South Pacific and Davis Strait until the eve of World War I, and a late attack on North Pacific right whales from San Francisco ended in the 1920s.

Despite the growing potential of mineral and vegetable oils, there was still a healthy demand for whale, as opposed to sperm, oil. However, neither Britain nor America could provide a successful technological response to the problem of diminishing returns on their investments. Little financial benefit was gained from applying steam power to whalers, and iron vessels had inferior insulation properties and lacked the resilience to resist ice pressure in the Arctic. Harpoon guns and rocket harpoons were introduced after 1815, but they were largely abandoned as more likely to frighten off whales than guarantee their capture. "Darting guns," which fired grenades into harpooned whales, were little better in causing fatal hemorrhage than hand lances. Most seriously, with right whales on the point of extinction, neither country found a means of attacking the vast stock of alternative whales.

Steam and gun

Modern whaling. Tradition taught that only right and sperm whales were worth hunting. So-called wrong whales—also called rorquals—included the blue (the largest animal ever to have existed), the fin, and the sei. With a top speed of 20 to 30 miles per hour, rorquals were too fast for the six-oared whale boats and too heavy to be held by them when—in contrast to right whales—they sank after being killed. It was a Norwegian, Svend Foyn of Tønsberg, who brought the various strands of modern whaling together between 1863 and 1870. With his 86-ton, seven-knot *Spes et Fides,* the first powerful steam-powered whale catcher, he replaced the old rowing boats. A forward-mounted gun fired a heavy harpoon equipped with a time-delay grenade, and the main engines were used, via a winch and spring arrangement, to play, raise, and tow whales for processing ashore. For the first time, carcasses were fresh enough for the oil and meat to be edible. Modern cookers and machinery extracted oil from inedible meat and bones, and the residue was ground into fertilizer or animal feed. The extra income thus generated helped balance the poor baleen yield of rorquals.

Foyn's success led to other shore stations on the Norwegian, Scottish, and Newfoundland coasts by the turn of the century. Stocks were already diminishing when interest in whale oil suddenly increased around 1904 as the production of soap and margarine ran ahead of world fat supplies. The hydrogenation process, turning oil into fat, opened up whaling to immense capital investment. Norwegian and British enterprises established bay stations in the Antarctic, South America, and South Africa, and the catch rose from fewer than 2,000 whales per annum around 1900 to more than 20,000 from 1911. By 1909 whales were hunted in the open seas by fleets consisting of steam catchers and a factory ship that carried fuel and supplies and processed the whales. This pelagic whaling rose in importance after World War I, largely accounting for a rapid rise in oil production in the late 1920s. By 1930 there were six shore stations, 41 factory ships, and 232 catchers in the Antarctic. Stern slips, better butchering machinery, and pressure cookers speeded up processing and helped to raise the yield of good quality oil well ahead of the requirements of the manufacturing companies. Although much capital and commercial organization was provided by Britain, this was the great period of Norwegian domination of the trade, with many of the expeditions and almost all the crewmen of Norwegian origin.

After World War II (during which some 30 floating factories were sunk), so important was whale oil to the fat rations of Europe that a wave of newer, larger factories and more powerful 18-knot diesel-engined catchers was built, backed up by aircraft and support shipping. The success enjoyed by British and Norwegian companies (with over 80 percent of the trade from 1945 to 1950) brought in other nations—notably The Netherlands, the U.S.S.R., and Japan. The hunt descended from larger to smaller whales as overfishing decimated the blue whale in the 1940s, the fin and humpback whales between 1955 and 1970, and the sei whale thereafter. Whaling shifted from the Antarctic (where some 1,400,000 whales were killed) to the North Pacific. A renewed attack on the sperm whale took place in the 1950s, when new uses were found for its oil.

Modern catcher boats were about 60 metres long and designed for quick turning. From a raised foredeck a bow gun accurately fired a two-metre harpoon of 54 kilograms as far as 25 metres. The harpoon was made of soft metal, so that it bent, but did not break, when the animal struggled. A time fuse then triggered an explosive charge to damage vital organs or cause massive bleeding. A nylon line running from the harpoon to a power winch brought in the whale when it was exhausted; on occasion, a second shot was required to kill the animal. Once alongside, the carcass was inflated with air to keep it afloat, and an identifying flag was affixed. The catcher sought more prey, eventually collecting the entire day's catch for delivery to the factory.

Modern factory-ship processing

Whale processing by modern and floating factories was broadly standardized and highly efficient. Carcasses were winched onto ramps, where they were dismembered with speed to release body heat before excessive putrefaction ensued. Blubber was flensed lengthwise in three sections—much like peeling a banana—chopped, and quickly fed through deck hatches into high-pressure steam cookers. The bone, which was porous and oily, was also cut up and subjected to pressure cooking for oil extraction, and the residue was ground and bagged as bone meal. Flesh not used for human consumption was similarly processed for oil, and the remaining solids were kiln-dried and marketed as animal feed. In less than one hour it was possible to dispose of all that was useful of a 100-ton blue whale.

About 1962, with no more concentrations of large whales, the commercial expeditions from Europe withdrew and left whaling chiefly to the Soviets and Japanese. Soviet enterprises were subsidized, while modern refrigeration allowed the Japanese to make a delicacy out of the meat, which Europeans had used—if at all—for animal feed or fertilizer. But even this whaling was doomed to failure as it rapidly extinguished the last of the "commercial" whales, the minke. By the 1980s the international whale trade was dead, although small-scale whaling continued.

Regulation. The demise of whaling and the whale was regularly forecast from the 1930s, but restraint was hampered by the selfishness of commerce and the ignorance of science. In 1931 a League of Nations International Whaling Convention led the way into restrictive regulations, whose partial success in the 1930s owed more to poor business than good sense. The International Whaling Commission (IWC), established in 1946 to conserve whale stocks, prohibited the killing of right and gray whales. It also limited the annual Antarctic kill to 15,000 Blue Whale Units (BWU; one BWU = two fin, 2.5 humpback, or six sei), and it created closed areas and seasons around the world. Enforcement was difficult, however, and the BWU standard was overoptimistic about total and optimum whale stocks. Modern scientific pressure, coinciding with commercial crisis, brought the BWU limit down to 2,300 by 1962 and protected the humpback (1963) and blue (1965); but it was not until 1972, when the United Nations voted in vain for a moratorium on whaling, that the BWU was replaced by a New Management Procedure, which established quotas for the remaining species. In 1979 floating factories were banned, except for minke whales. Finally, to protect remaining stocks, the IWC agreed in 1982 to prohibit commercial whaling beginning in 1986, but several countries refused to agree. Residual commercial whaling continued, often under the guise of capturing specimens for scientific research.

Whaling moratorium

Whale products. *Whale oil.* This is a compound of fatty acids and glycerol, plus other alcohols and free fatty acids, the latter increasing with degeneration and producing rancidity. Premodern oil was inedible and was used principally for lighting, lubrication, and the manufacture of varnish, leather, linoleum, rough cloth (especially jute), and bottled gas for railway and similar uses. Until recently the finest lubricating oil came from the jawbones of small whales. Modern fresh oil, after being hardened to a fat, was used in margarine and soap; vegetable oil was not a practical alternative until the late 1930s. Whale liver oil was a major source of vitamin D through the 1960s.

Sperm oil. Waxy and inedible, sperm oil was a superior lighting oil. It was little used in the modern period apart from certain toiletries and pharmaceuticals. From 1950 more could be used in soap, owing to advances in oil chemistry—hence the last great attack on sperm whales.

Spermaceti. This liquid wax from the head of the sperm whale produced, on freezing and pressing, a brittle wax highly prized for candles.

Baleen. Also called whalebone, this product was cut from the large, hairy plates with which right whales filter krill during passive feeding. Because it is springy and retains shapes imposed with heat, it was used for corsets, knife handles, umbrella ribs, and brushes.

Sperm whale teeth. Widely used for scrimshaw, they are now copied in plastic.

Ambergris. A waxy pathological accretion occasionally found in the intestine of sperm whales or floating in the sea, ambergris was for many years highly prized as a base in perfumery.

Whale meat. This was of no value in early commercial whaling, because of rapid putrefaction. Modern shore and floating factories produced meat meal for animal consumption or fertilizer until refrigerated ships facilitated recovery of edible meat in the late 1940s. Most countries rejected it except as dog food, but its high value in Japan supported the last phase of commercial whaling. (G.J.)

BIBLIOGRAPHY

Commercial fishing: The productivity of the seas and the exploitation of the living resources in the world's oceans are illustrated in EOOD AND AGRICULTURE ORGANIZATION OE THE UNITED NATIONS, *Atlas of the Living Resources of the Seas,* 4th ed. (1981). ORGANISATION EOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Multilingual Dictionary of Fish and Fish Products,* 2nd ed. (1978, reprinted with corrections, 1984), provides comprehensive information on fish, fish products, and other marine life used commercially. Scientific research supporting commercial fishing is discussed in TAIVO LAEVASTU and MURRAY L. HAYES, *Fisheries Oceanography and Ecology* (1981); TONY J. PITCHER and PAUL J.B. HART, *Fisheries Ecology* (1982); and MAURICE E. STANSBY, *Industrial Fishery Technology,* 2nd ed. (1976). Developments in commercial fishing are detailed in studies of local areas, such as PETER POWNALL, *Fisheries of Australia* (1979); and PETER R. SINCLAIR, *State Intervention and the Newfoundland Fisheries* (1987). C.R.P.C. BRANSON (ed.), *Fishermen's Handbook,* 2nd ed. (1987), explains and illustrates many situations occurring in commercial fishing.

Equipment, facilities, and methods: JOHN C. SAINSBURY, *Commercial Fishing Methods: An Introduction to Vessels and Gears,* 2nd ed. (1986), describes the basics of the fishing industry. ANDRES VON BRANDT, *Fish Catching Methods of the World,* 3rd rev. ed. (1984), surveys fishing methods and equipment, from the most primitive to the totally computerized and automated. DAG PIKE, *Fishing Boats and Their Equipment* (1979), examines the design factors of boats and their effect on fishing productivity. JAN-OLOE TRAUNG (ed.), *Fishing Boats of the World,* 3 vol. (1955–67), provides excellent basic information on boats for various fishing methods. Specific methods and technologies are discussed in *Echo Sounding and Sonar for Fishing* (1980), a Food and Agriculture Organization fishing manual; DAVID B. THOMSON, *Seine Fishing: Bottom Fishing with Rope Warps and Wing Trawls,* rev. ed. (1981), and *Pair Trawling and Pair Seining: The Technology of Two-Boat Fishing* (1978); J.H. MERRITT, *Refrigeration on Fishing Vessels,* rev. ed. (1978); and J.J. CONNELL (ed.), *Advances in Fish Science and Technology* (1980). *Fishing Ports and Markets* (1970) is a collection of papers from a conference held under the auspices of the Food and Agriculture Organization.

Fisheries: The resources, ecology, and management of marine and freshwater fisheries are discussed in ROBERT J. BROWNING, *Fisheries of the North Pacific: History, Species, Gear, & Processes,* rev. ed. (1980); ROBERT T. LACKEY and LARRY A. NIELSEN (eds.), *Fisheries Management* (1980); FREDERICK W. BELL, *Food from the Sea: The Economics and Politics of Ocean Fisheries* (1978); STEPHEN CUNNINGHAM, MICHAEL R. DUNN, and DAVID WHITMARSH, *Fisheries Economics* (1985); G.C. EDDIE, *Engineering, Economics, and Fisheries Management* (1983); TOIVO LAEVASTU and HERBERT A. LARKINS, *Marine Fisheries Ecosystem: Its Quantitative Evaluation and Management* (1981); ROBIN L. WELCOMME, *Fisheries Ecology of Floodplain Rivers* (1979); ROBIN G. TEMPLETON (ed.), *Freshwater Fisheries Management* (1984); and SHELBY D. GERKING (ed.), *Ecology of Freshwater Fish Production* (1978). Ongoing research and developments in the field are reported in *Fisheries of the United States* (annual); and *Ocean Yearbook.* (J.C.Sa./D.Pi.)

Aquaculture: Various aspects of commercial fish farming throughout the world are discussed in ELISABETH MANN BORGESE, *Seafarm: The Story of Aquaculture* (1980); ROBERT KIRK, *A History of Marine Fish Culture in Europe and North America* (1987); MARCEL HUET, *Textbook of Fish Culture: Breeding and Cultivation of Fish,* 2nd ed. (1986; originally published in French, 1970); E. EVAN BROWN, *World Fish Farming: Cultivation and Economics,* 2nd ed. (1983); MALCOLM C.M. BEVERIDGE, *Cage Aquaculture* (1987); JAMES E. LANNAN, R. ONEAL SMITHERMAN, and GEORGE TCHOBANOGLOUS (eds.), *Principles and Practices of Pond Aquaculture* (1986); ROBERT R. STICKNEY, *Principles of Warmwater Aquaculture* (1979); FREDRICK W. WHEATON, *Aquacultural Engineering* (1977, reprinted 1985); JOHN P. STEVENSON, *Trout Farming Manual,* 2nd ed. (1987); ROBERT R. STICKNEY (ed.), *Culture of Nonsalmonid Freshwater Fishes* (1986); and EREDRICK W. WHEATON and THOMAS B. LAWSON, *Processing Aquatic Food Products* (1985). A good overview article is WILLIAM H. QUEEN, "Aquaculture: A Renewal of Interest," *Currents,* 3(3):20–25 (1988). (C.H.A.)

Whaling: Early descriptions of whaling include W. SCORESBY, *An Account of the Arctic Regions with a History and Description of the Northern Whale-Fishery,* 2 vol. (1820, reprinted 1969); and ALEXANDER STARBUCK, *History of the American Whale Fishery from Its Earliest Inception to the Year 1876* (1878, reissued with a new preface, 2 vol., 1964), featuring a list of all known voyages of 1715–1876. Early modern surveys, some of them with fascinating descriptions of whales, include J.T. JENKINS, *A History of the Whale Fisheries: From the Basque Fisheries of the Tenth Century to the Hunting of the Finner Whale at the Present Date* (1921, reprinted 1971); and R.B. ROBERTSON, *Of Whales and Men* (1954, reprinted 1969), a contemporary whaling narrative. Recent histories include LEONARD HARRISON MATTHEWS *et al., The Whale* (1968, reissued 1975), a general work on whaling; E.J. SLIJPER, *Whales,* trans. from Dutch, 2nd ed., edited by RICHARD J. HARRISON (1979); and HARRY MORTON, *The Whale's Wake* (1982).

The standard work on modern whaling remains J.N. TØNNESSEN and A.O. JOHNSEN, *The History of Modern Whaling* (1982; originally published in Norwegian, 4 vol., 1959–70). N.A. MACKINTOSH, *The Stocks of Whales* (1965); and K. RADWAY ALLEN, *Conservation and Management of Whales* (1980), examine the problem of extinction. Valuable information on whaling in the Arctic is found in *Arctic Whaling* (1984), one of a series of papers published by the Arctic Centre, University of Groningen, Neth. (G.J.)

Flatworms: Phylum Platyhelminthes

The platyhelminths, or flatworms, constitute the phylum Platyhelminthes, a group of invertebrate animals that are free-living as well as parasitic—*i.e.*, living on or in another organism and securing nourishment from it. They are bilaterally symmetrical (*i.e.*, the right and left sides are similar), usually flattened, and lack respiratory, skeletal, and circulatory systems; no body cavity (coelom) is present. The body is not divided into true segments; spongy connective tissue (mesenchyme) constitutes the so-called parenchyma and fills the space between organs. Flatworms, generally hermaphroditic—functional reproductive organs of both sexes occurring in one individual—are the lowest invertebrates to possess three embryonic layers—endoderm, mesoderm, and ectoderm—and to have a head region that contains concentrated sense organs and nervous tissue (brain).

The phylum consists of five classes: Trematoda (flukes), Cestoda (tapeworms), Turbellaria (planarians), Monogenea, and Aspidocotylea (or Aspidobothria). Members of all classes except Turbellaria are parasitic during all or part of the life cycle. Most turbellarians are exclusively free-living forms. Approximately 13,000 species of flatworms have been described.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313, and the *Index*.

This article is divided into the following sections:

GENERAL FEATURES

Fluke and tapeworm infestations

Importance. Platyhelminthes are of particular economic interest because many species of flukes are parasitic in man, in domestic animals, or in both. In Europe and in North and South America, tapeworm infestations of man have been greatly reduced as a consequence of routine meat inspection. But where sanitation is poor and meat eaten undercooked, the incidence of tapeworm infestations is high. In the Baltic countries much of the population is infested with the broad tapeworm (*Diphyllobothrium latum*); in parts of the southern United States a small proportion of the population may be infested with the dwarf tapeworm (*Hymenolepis nana*). In Europe and the United States the beef tapeworm (*Taenia saginata*) is not uncommon due to the habit of eating undercooked steaks or other beef products.

Parasites in immature stages (larvae) can cause serious damage to the host. A larval stage of the gid parasite of sheep (*Multiceps multiceps*) usually lodges in the sheep brain. Fluid-filled hydatid cysts (*i.e.*, sacs containing many cells capable of developing into new individuals) of *Echinococcus* may occur almost anywhere in the body of sheep. Hydatids of the liver, brain, or lung of man are often fatal. Infestation occurs only where man lives in close association with dogs that have access to infested sheep for food.

Thirty-six or more species of flukes have been reported as parasitic in humans. Endemic (local) centres of infection occur in virtually all countries; widespread infections occur in the Far East, Africa, and tropical America. Many species are ingested as cysts, called metacercariae, in uncooked food—*e.g.*, the lung fluke *Paragonimus westermani* found in crayfish and crabs, the intestinal flukes *Heterophyes heterophyes* and *Metagonimus yokogawai* and the liver fluke *Opisthorchis sinensis* in fish, and the intestinal fluke *Fasciolopsis buski* on plants. Free-swimming larvae (cercariae) of blood flukes penetrate the human skin directly. In man these parasites and others listed below cause much misery and death. Control of certain flukes through the eradication of their mollusk hosts has been attempted but without much success.

Schistosomiasis (bilharziasis) is a major human disease caused by three species of the genus *Schistosoma*, known collectively as blood flukes. Africa and western Asia (*e.g.*, Iran, Iraq) are endemic centres for *S. haematobium; S. mansoni* also is found in these areas, as well as in the West Indies and South America. In the Far East, *S. japonicum* is the important blood fluke.

Among domestic animals, the sheep liver fluke (*Fasciola hepatica*) may cause debilitating and fatal epidemics (liver rot) in sheep. These animals become infected by eating metacercariae encysted on grass. Monogenea are common pests on fish in hatcheries and home aquariums (see also DISEASE: *Diseases of animals*).

Size range and diversity of structure. Most of the Turbellaria are less than five millimetres (0.2 inch) long, and many are microscopic in size. The largest of this class are the planarians, which may reach 0.5 metre (about 20 inches) in length. Trematoda are mostly from less than one to 10 millimetres (0.04 to 0.4 inch) long; some species, however, may grow to several centimetres. The smallest Cestoda are about one millimetre (0.04 inch) long, but some exceed 15 metres (50 feet) in length. The Monogenea range in length from 0.5 to 30 millimetres (0.02 to 1.2 inches). Aspidocotylea are from a few millimetres to 100 millimetres in length.

Distribution and abundance. In general, free-living flatworms can occur wherever there is moisture. Except for one group of turbellarians, the temnocephalids, flatworms are cosmopolitan in distribution. They occur in both fresh water and salt water and occasionally in terrestrial habitats that are moist, especially in tropical and subtropical regions. The temnocephalids, which are parasitic on freshwater crustaceans, occur primarily in Central and South America, Madagascar, New Zealand, Australia, and islands of the South Pacific.

Some flatworm species occupy a very wide range of habitats. One of the most cosmopolitan and most tolerant of different ecological conditions is the turbellarian *Gyratrix hermaphroditus*, which occurs in fresh water at elevations from sea level to 2,000 metres (6,500 feet) as well as in saltwater pools. Adult forms of parasitic flatworms are confined almost entirely to specific vertebrate hosts; the larval forms, however, occur in vertebrates and in invertebrates, especially in mollusks, arthropods (*e.g.*, crabs), and annelids (*e.g.*, marine worms). They are cosmopolitan in distribution, but their occurrence is closely related to that of the intermediate host or hosts.

NATURAL HISTORY

Life cycle. *Reproduction.* With very few exceptions, platyhelminthes are hermaphroditic, and their reproductive systems are generally complex. Numerous testes but only one or two ovaries are usually present in these flatworms. The female system is unusual in that it is separated into two structures: the ovaries and the vitellaria, often known as the vitelline glands or yolk glands. In contrast, in most higher animals the yolk is part of the egg. The cells of the vitellaria form yolk and eggshell components. In some groups, particularly those that live primarily in water or have an aqueous phase in the life cycle, the eggshell consists of a hardened protein known as sclerotin, or tanned protein. Most of this protein comes from the vitellaria. In other groups, especially those that are primarily terrestrial or have a terrestrial phase in their life cycle, the eggshells are composed of another protein, keratin, a tougher material that is more resistant to adverse environmental conditions.

Separation of the female reproductive system

The general structure of the reproductive system may be seen in Figure 2. In the tapeworms, the tapelike body is generally divided into a series of segments, or proglottids, each of which develops a complete set of male and female genitalia. A rather complex copulatory apparatus consists of an evertible (capable of turning outward) penis, or cirrus, in the male and a canal, or vagina, in the female. Near its opening the female canal may differentiate into a variety of tubular organs. Fertilized eggs are often stored in a saclike uterus, which may become greatly distended; in tapeworms, it may fill a whole segment.

Each male and female reproductive system may have its own external opening, or gonopore, or the terminal regions of each system may join to form a common genital atrium (Figure 2), or passage, and a genital pore.

Either cross-fertilization (*i.e.,* involving two individuals) or self-fertilization may occur; self-fertilization is probably more common. Some free-living flatworms perform a type of copulation known as hypodermic impregnation, whereby the penis of one animal pierces the epidermis of another and injects sperm into the tissues. Some forms reproduce asexually—*i.e.,* they produce chains that eventually separate to form individuals.

Modes of fertilization

Development. The life cycles of the free-living forms are relatively simple. Eggs are laid singly or in batches. Frequently they are attached to some object or surface by an adhesive secretion. After a period of embryonation (*i.e.,* the formation of the first larval stage) minute worms emerge, feed, develop genitalia, and become adult.

Parasitic platyhelminths undergo very complex life cycles, often involving several larval stages in other animals—the intermediate hosts; these hosts may be invertebrate or vertebrate.

The simplest cycle in parasitic platyhelminths occurs in the Monogenea, which have no intermediate hosts. The majority of the Monogenea are ectoparasitic (externally parasitic) on fish. The eggs hatch in water. The larva, known as an oncomiracidium, is heavily ciliated (has hairlike projections) and bears numerous posterior hooks. It attaches to a host, grows, and matures. In some species (*e.g., Polystoma integerrimum*) parasitic in frogs, maturation of the genitalia is synchronized with maturation of the host and apparently is controlled by the endocrine system of the latter.

In the life cycle of flukes of the subclass Digenea, mollusks serve as the intermediate host. Eggs of Digenea usually hatch in water or in a snail host. The first larval stage, the miracidium, generally is free-swimming and penetrates a freshwater or marine snail, unless it has already been ingested by one. Within this intermediate host, the parasite passes through some or all of a series of further larval stages known as sporocysts, rediae, and cercariae. Cercariae are essentially young flukes with tails. They either penetrate the host or are ingested by it. Tapeworms of the subclass Eucestoda are generally transmitted from host to host by direct ingestion of eggs; by ingestion of intermediate hosts containing larval stages; and, very rarely, by passage of a larva from an intermediate host through a skin wound into another intermediate host.

Transmission to a human host through a skin wound is most likely to occur in Asia, where frogs infested with tapeworm larvae are sometimes used to treat wounds. The tapeworm, *Hymenolepis nana,* parasitic in rodents and man, can complete its life cycle without an intermediate host. Certain species of trematodes and cestodes show a tendency toward progenesis, in which adult features—such as the appearance of genital rudiments—appear in the larva. In some cases of progenesis the worm achieves sexual maturity in the intermediate host.

Regeneration. The ability to undergo tissue regeneration, beyond simple wound healing, occurs in two classes of Platyhelminthes: Turbellaria and Cestoda.

Turbellaria. Turbellarians, planaria particularly, have been commonly used in regeneration research. The greatest regenerative powers exist in species capable of asexual reproduction. Pieces from almost any part of the turbellarian *Stenostomum,* for example, can reorganize into completely new worms. In some cases regeneration of very small pieces may result in the formation of imperfect (*e.g.,* headless) organisms.

In other Turbellaria, regeneration of the head is limited to pieces from the anterior region or to tissues containing the cerebral ganglion (brain). The region anterior to this ganglion is incapable of regeneration, but if cuts are made posterior to it, many species can replace the entire posterior region, including the pharynx and the reproductive system. In the cut pieces, polarity is retained; *i.e.,* the anterior zone of the cut piece regenerates the head and the posterior region regenerates the tail. If a region in front of the pharynx is transplanted into the posterior region

Polarity

of another individual, it influences that region to form a pharyngeal zone that eventually differentiates a pharynx. This new pharyngeal zone is now said to be determined and, if removed, will regenerate again into a new pharynx.

There is evidence that a special type of cell, a neoblast, is concerned in planarian regeneration. Neoblasts, rich in ribonucleic acid (RNA), which plays an essential role in cell division, appear in great numbers during regeneration. Similar cells, apparently inactive, occur in the tissues of whole organisms (see also GROWTH AND DEVELOPMENT: *Biological regeneration*).

Cestoda. Regeneration, although rare in the parasitic worms in general, does occur in the cestodes. Most tapeworms appear to be capable of regeneration from the head (scolex) and neck region. This property often makes it difficult to treat man for tapeworms; treatment may eliminate only the body, or strobila, leaving the scolex still attached to the intestinal wall of the host and thus capable of producing a new strobila, which reestablishes the infestation. Several species of cestode larvae can regenerate themselves from cut regions. A branched larval form of *Sparganum prolifer,* a human parasite, may undergo both asexual multiplication and regeneration.

Ecology. Turbellaria are adapted to a wide range of environments, and many species are resistant to extreme environmental conditions. Some occur in coastal marine habitats—in sand, on or under rocks, and in or on other animals or plants. Some marine species occur at relatively great depths in the sea; others are pelagic (*i.e.,* living in the open sea). Freshwater species are found in ponds, lakes, rapidly flowing rivers, and streams. Temporary freshwater pools may contain adult forms that survive periods of dryness in an encysted state. Some aquatic species exhibit considerable tolerance to osmotic changes—*i.e.,* to differences in salt concentrations of the water; a marine species *Coelogynopora biarmata,* for example, has also been found in freshwater springs.

Terrestrial species of Turbellaria occur in soil, moist sand, leaf litter, mud, under rocks, and on vegetation. Some have been found in pools in the desert and in caves. Cave-dwelling species tend to show loss of eyes and pigment.

Tolerance of temperature extremes

Some species are able to stand considerable temperature ranges; for example, *Crenobia alpina,* which occurs in alpine streams, apparently can survive temperatures of −40° to −50° C (−40° to −58° F). Remarkable heat tolerance is exhibited by *Macrostomum thermale* and *Microstomum lineare,* which are found in hot springs at 40°–47° C (104°–117° F). *M. lineare* can also tolerate temperatures as low as 3° C (37° F).

Many Turbellaria live in association with plants and animals. Marine algae, for example, frequently harbour many species, often in large numbers. Turbellarians most commonly associate with animals such as echinoderms (*e.g.,* starfish), crustaceans (*e.g.,* crabs), and mollusks. Less commonly, associations occur with sipunculids (tiny marine invertebrates), annelid worms, arachnids (*e.g.,* spiders), coelenterates (*e.g.,* jellyfish), other turbellarians, and lower vertebrates. An interesting feature of these associations is that species within a turbellarian family tend to associate with one type of organism; for example, almost all members of the family Umagillidae associate with echinoderms.

In a few cases, the association is considered parasitic; *i.e.,* the turbellarians obtain all nourishment from the host. Most of these species belong to the order Rhabdocoela, in which the alimentary canal is either absent or reduced. In a few hosts they cause so-called parasitic castration—*i.e.,* suppression of gonad maturation in the host organism.

Among the turbellaria that are parasitic or commensal (*i.e.,* living in close association with but not harmful to another organism) the Temnocephalida are best adapted for attachment to other organisms. They have a large saucer-shaped posterior adhesive organ and anterior tentacles that are also used for adhesion. All temnocephalids occur on freshwater hosts, mainly crustaceans but also mollusks, turtles, and jellyfish.

The tendency to associate with other animals apparently represents a definite evolutionary trend among the platyhelminths; permanent associations essential to the survival of a species could develop from loose associations, which could also give rise to parasitic forms, such as the Trematoda and Cestoda. The free-living larval stages that frequently occur in these groups play a major role in the dissemination of the species.

The ecology of the parasitic groups (*i.e.,* Cestoda and Trematoda) is particularly complex, because as many as four hosts may be involved in the life cycle. In the case of the broad tapeworm, for example, man serves as the final (or definitive) host, various species of fish as one intermediate host, and species of a small water crustacean (*Cyclops*) as another intermediate host. It is clear that the broad tapeworm (*Diphyllobothrium latum*) can occur only where an intimate ecological association exists among the three host groups.

Adaptation to the microenvironment of the host

In addition to adapting to the general external environment, individuals at each stage of the life cycle of a parasite must adapt to the microenvironment provided by the host. Adaptations include not only obvious features, such as suckers or hooks for attachment, but also those associated with the biochemical and physiological conditions imposed by the host. Parasites frequently utilize the physiological and biochemical properties of a new host, especially those that differ markedly from the external environment, in order to trigger the next developmental stage—*e.g.,* several species of cestodes are stimulated to mature sexually by the high body temperature (40° C) of their bird host, which contrasts sharply with the low body temperature of the cold-blooded fish host of the larval stage. The unusually intimate association of certain flukes (subclass Digenea) with mollusks suggests that flukes were originally parasites of mollusks and that they later developed an association with other hosts.

Knowledge of the ecology both of a platyhelminth parasite and of its intermediate host(s) is essential if control measures against the pest are to be effective. Man's alterations of the environment sometimes increase the occurrence of platyhelminth diseases. The Aswan High Dam in Egypt, for example, has produced conditions especially favourable for the breeding of the snail that serves as the intermediate host of the blood fluke (*Schistosoma mansoni*). In this case, as with many trematode infestations, man exposes himself to the disease by bathing in water containing infective larvae (cercariae) released from infested snails; the cercariae enter directly through the skin. Certain other human diseases of platyhelminth origin—such as hydatid (cyst) disease, caused by the tapeworm *Echinococcus granulosus*—owe their survival and dissemination to man's close ecological association with dogs.

In the parasitic platyhelminth groups (*e.g.,* the Monogenea) that do not normally utilize intermediate hosts, there is a close ecological association between egg release and production of young of both the parasite and its host; infection of the next generation of host could not otherwise occur.

Many platyhelminths show highly specific adaptations to internal host environments. Many monogeneans, for example, show a marked preference for a particular gill arch in a fish. The scolex (head) of certain tapeworms of elasmobranch fishes (*e.g.,* sharks, skates, and rays) is highly specialized and can satisfactorily attach only to the gut of a fish possessing a complementary structure.

FORM AND FUNCTION

External features. Some Turbellaria are gray, brown, or black, with mottled or striped patterns. Others, which contain algae in the mesenchyme, are green or brown. Parasitic flatworms usually have no pigment, but cestodes may be coloured by food (*e.g.,* bile, blood) in their gut. Some parasitic forms may show masses of dark eggs through a translucent, creamy, or whitish tissue.

The flatworm body plan

The typical flatworm body is flattened and leaflike or tapelike (Figure 2). The head may be set off from the body or grade imperceptibly into it. The anterior (head) end can usually be distinguished from the posterior end in free-living forms by the presence of two pigment spots, which are primitive eyes. In the case of the tapeworm, the scolex is usually conspicuous for its breadth. The strobila (body) typically consists of proglottids, each of which is usually a self-sufficient reproducing unit with all of the sexual

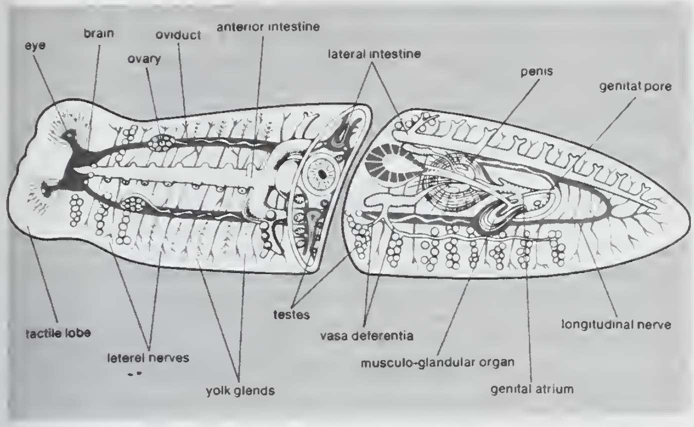

Figure 2: General structure of a platyhelminth, as exemplified by a freshwater turbellarian, *Procotyla fluviatilis*.

Reprinted with permission of The Macmillan Company from *Invertebrate Zoology* by R Hegner and J Engemann Copyright © by The Macmillan Company, 1968

organs necessary to reproduce. The number of proglottids may vary from three in some species to several hundreds in others. Organs of attachment on the scolex may, in addition to suckers, consist of hooks, spines, or various combinations of these.

The structure and function of the body covering, or tegument, differs markedly between free-living and parasitic forms. In free-living forms, the body covering is typically an epidermis consisting of one layer of ciliated cells—*i.e.,* cells with hairlike structures—the cilia being confined to specific regions in some species. In the parasitic groups—flukes, tapeworms, and monogeneans—the tegument shows striking modifications associated with the parasitic way of life. It once was thought that the tegument is a nonliving secreted layer; it is now known, however, that the tegument of parasites is (Figure 3) metabolically active and consists of cells not separated from one another by cell walls (*i.e.,* a syncytium). The tegument itself consists of cytoplasmic extensions of tegumental cells, the main bodies of which lie in what may be described as the "subcuticular" zone, although a true cuticle is not present. A membrane separates the inner zone of the tegumental cells, the so-called perinuclear cytoplasm, from the surface syncytium, or distal cytoplasm (Figure 3).

The surface of tapeworms and monogeneans is drawn out into spinelike structures called microtriches, or microvilli. The microtriches probably help to attach the parasite to the gut of the host, absorb nutritive materials, and secrete various substances. In the flukes, microtriches are lacking, but spines are frequently present.

From (Left) R Hegner and J Engemann, *Invertebrate Zoology*, (Right) J Smyth, *The Physiology of Cestodes*

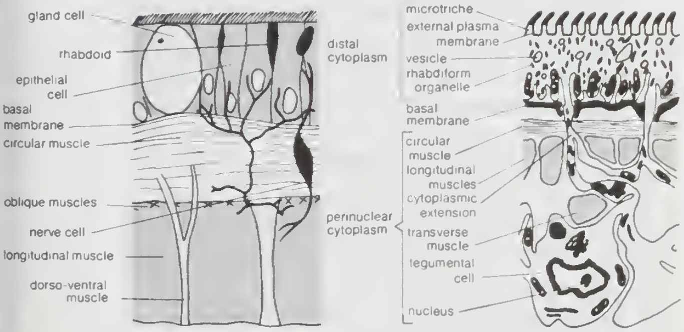

Figure 3: Comparison of the body wall in (left) a turbellarian, a free-living platyhelminth, and in (right) a tapeworm, a parasitic platyhelminth.

Embedded in the epidermis of turbellarians are ovoid or rod-shaped bodies (rhabdoids, see Figure 3) of several sorts; of uncertain function, the bodies frequently are concentrated dorsally or may be clustered anteriorly as rod tracts opening at the apex. Rhabdoids are absent in flukes and tapeworms.

Internal features. Beneath the epidermis of turbellarians is a homogeneous or lamellated basal membrane. Club-shaped mesenchymal gland cells, opening externally, generally are present in all flatworms. In turbellarians two major types of mesenchymal glands occur: one produces a slimy material upon which the organisms creep; the other secretes an adhesive substance for capture of prey, for adhesion, and for cementing egg capsules to a suitable surface. The larvae of parasitic forms generally possess similar glands whose secretions are used for adhesion, for producing cyst walls around resting stages, and for penetrating hosts; some adult parasites have glands for adhesion and, in trematodes, for softening and digesting host tissues.

Mesenchyme

The mesenchyme consists of fixed and free cells as well as a fibrous matrix. A fluid occupies the minute open spaces and serves for distribution of nutrients and wastes. The mesenchymal cells in certain groups may differentiate during growth to become sex cells or may function in asexual reproduction in repair or in regeneration.

Nervous system. The main ganglia, or nerve centres, of the nervous system and the major sense organs are generally concentrated at the anterior end. Typically, the primitive brain of the flatworm consists of a bilobed mass of tissue with lateral longitudinal nerve cords connected by transverse connectives, thus forming a rather ladderlike structure or grid running the greater length of the organism (Figure 2). Free-living forms commonly have two longitudinal cords, but some tapeworms have as many as 10. Sensory receptors occur in all groups.

Musculature. The well-developed muscular system present in flatworms is comprised of a subcuticular musculature consisting of layers of circular, longitudinal, and diagonal muscles close to the epidermis, and a mesenchymal musculature consisting of dorsoventral, transverse, and longitudinal fibres passing through the mesenchyme. In general, platyhelminths are capable of extensive body contraction and elongation.

Digestive and excretory systems. The blind-ending intestine of trematodes consists of a simple sac with an anterior or midventral mouth or a two-branched gut with an anterior mouth; an anus is usually lacking, but a few species have one or two anal pores. Between the mouth and the intestine are often a pharynx and an esophagus receiving secretions from glands therein. The intestine proper, lined with digestive and absorptive cells, is surrounded by a thin layer of muscles that effect peristalsis; *i.e.,* they contract in a wavelike fashion, forcing material down the length of the intestine. In many larger flukes lateral intestinal branches, or diverticula, bring food close to all internal tissues. Undigested residue passes back out of the mouth.

The digestive system of Turbellaria typically consists of mouth, pharynx, and intestine. In the order Acoela, however, only a mouth is present; food passes directly from the mouth into the parenchyma, to be absorbed by the mesenchymal cells. Tapeworms lack digestive systems.

The excretory system consists of protonephridia. These are branching canals ending in so-called flame cells—hollow cells with bundles of constantly moving cilia.

Complex feeding mechanisms

Nutrition. *Free-living forms.* Free-living platyhelminths (Turbellaria), mostly carnivorous, are particularly adapted for the capture of prey. Their encounters with prey appear to be largely fortuitous, except in some species that release ensnaring mucus threads. Because they have developed various complex feeding mechanisms, most turbellarians are able to feed on organisms much larger than themselves, such as annelids, arthropods, mollusks, and tunicates (*e.g.,* sea squirts). In general, the feeding mechanism involves the pharynx which, in the most highly developed forms, is a powerful muscular organ that can be protruded through the mouth. Flatworms with a simple ciliated pharynx are restricted to feeding on small organisms such as protozoans and rotifers, but those with a muscular pharynx can turn it outward, thrust it through the tegument of annelids and crustaceans, and draw out their internal body organs and fluids. Turbellaria, with a more advanced type of pharynx, can extend it over the captured prey until the animal is completely enveloped.

Digestion is both extracellular and intracellular. Digestive enzymes (biological catalysts), which mix with the food in the gut, reduce the size of the food particles. This partly digested material is then engulfed (phagocytized) by cells or absorbed; digestion is then completed within the gut cells.

Parasitic forms. In the parasitic groups with a gut (Trematoda and Monogenea), both extracellular and intracellular digestion occur. The extent to which these processes take place depends on the nature of the food. When fragments of the host's food or tissues other than fluids or semifluids (*e.g.,* blood and mucus) are taken as nutrients by the parasite, digestion appears to be largely extracellular. In those that feed on blood, digestion is largely intracellular, often resulting in the deposition of hematin, an insoluble pigment formed from the breakdown of hemoglobin. This pigment is eventually extruded by disintegrating gut cells.

Despite the presence of a gut, trematodes seem able to absorb certain materials, such as glucose, through the metabolically active tegument covering the body surface. Tapeworms, which have no gut, absorb all food through the tegument. The entry of amino acids (the structural units of proteins) and small molecules of carbohydrate (*e.g.,* sugars) through the tegument occurs by a mechanism called active transport, in which molecules are taken up against a concentration gradient. This process, similar to that in the vertebrate gut, requires the expenditure of energy. There is also evidence that cestodes may be able to digest materials in contact with the tegument by means of so-called membrane digestion, a little-understood process.

Metabolism. Both free-living and parasitic platyhelminths utilize oxygen when it is available. Most of the parasitic platyhelminths studied have a predominantly anaerobic metabolism (*i.e.,* not dependent upon oxygen). This is true even in species found in habitats—such as the bloodstream—where oxygen is normally available.

Parasitic platyhelminths are made up of the usual tissue constituents—protein, carbohydrates, and lipids—but, compared to other invertebrates, the proportions differ somewhat; *i.e.,* the carbohydrate content tends to be relatively high and the protein content relatively low. In larval and adult cestodes, carbohydrate occurs chiefly as animal starch, or glycogen, which acts as the main source of energy for species in low oxygen habitats. The level of glycogen, like other chemical constituents, can fluctuate considerably, depending on the diet or feeding habits of the host. In some species, more than 40 percent of the worm's dried weight is glycogen.

Because carbohydrate metabolism is important in parasitic flatworms, a substantial amount of carbohydrate must be present in the host diet to assure normal growth of the parasite. Hence the growth rate of the rat tapeworm (*Hymenolepis diminuta*) is a good indicator of the quantity of carbohydrate ingested by the rat. Experiments have shown that most parasitic worms have the capability of utilizing only certain types of carbohydrate. All tapeworms that have been studied thus far utilize the sugar glucose. Many tapeworms can also utilize galactose, but only a few can utilize maltose or sucrose.

An unusual constituent of both trematodes and cestodes is a round or oval structure called a calcareous corpuscle; large numbers of them occur in the tissues of both adults and larvae. Their function has not yet been established, but it is believed that they may act as reserves for such substances as calcium, magnesium, and phosphorus.

The chief proteins in cestodes and trematodes are keratin and sclerotin. Keratin forms the hooks and part of the protective layers of the cestode egg and the cyst wall of certain immature stages of trematodes. Sclerotin occurs in both cestode and trematode eggshells, especially in those that have larval stages associated with aquatic environments.

Requirements for egg hatching

Platyhelminth eggs hatch in response to a variety of different stimuli in different hosts. Most trematode eggs require oxygen in order to form the first larval stages and light in order to hatch. Light is thought to stimulate the release of an enzyme that attacks a cement holding the lid (operculum) of the egg in place. A similar mechanism probably operates in cestodes (largely of the order Pseudophyllidea) whose life cycles involve aquatic intermediate hosts or definitive hosts, such as birds or fish.

In many cestodes, especially those belonging to the order Cyclophyllidea, the eggs hatch only when they are ingested by the host. When the host is an insect, hatching sometimes is apparently purely a mechanical process, the shell being broken by the insect's mouthparts. In vertebrate intermediate hosts, destruction of the shell depends largely on the action of the host's enzymes. Activation of the embryo within the shell and its subsequent release depend on other factors, including the amount of carbon dioxide present, in addition to the host's enzymes. Factors involving a vertebrate host are also important in establishing trematode or cestode infections after encysted or encapsulated larval stages have been ingested. Under the influence of the same factors, tapeworm larvae are stimulated to evaginate their heads (*i.e.,* turn them inside out, so to speak), a process that makes possible their attachment to the gut lining.

EVOLUTION

Origin of Turbellaria

The origin of the platyhelminths and the evolution of the various classes have not been positively settled. There are, however, two main lines of thought. According to the more widely accepted view, the Turbellaria and an aberrant group, the Ctenophora, have been derived independently from the lower Coelenterata. In the alternative view, the Turbellaria are derived from the Ciliata and the Ctenophora from the Turbellaria.

It is generally believed that the parasitic groups are derived from the Turbellaria, many of which form close associations with other animals. These associations often show host specificity, a characteristic of truly parasitic forms. There are a number of views regarding the evolutionary relationships among the various parasitic groups. One school of thought proposes that rhabdocoel turbellarians gave rise to monogeneans; these, in turn, gave rise to digeneans, from which the cestodes were derived. Another view is that the rhabdocoel ancestor gave rise to two lines; one gave rise to monogeneans, who gave rise to digeneans, and the other line gave rise to cestodes. A further modification of the latter view, based largely on the study of the larval forms, proposes that cestodes were derived from monogeneans.

In considering the evolution of the parasitic groups, the digeneans should be mentioned in particular. The life cycle of digeneans is dominated by mollusks, which invariably act as intermediate hosts. This condition has led to the widely accepted view that digeneans were originally parasites of mollusks and later formed an association with vertebrates; the vertebrates, in turn, became incorporated into the life cycle as definitive hosts.

CLASSIFICATION

Distinguishing taxonomic features. The phylum Platyhelminthes is grouped with several other phyla (Nemertea, Rotifera, Nematoda, Gastrotricha, Acanthocephala, and Nematomorpha) as acoelomate triploblasts—*i.e.,* lacking a body cavity and with three embryonic layers: endoderm, mesoderm, and ectoderm. These phyla also represent animals that are unsegmented and whose body space tends to be occupied by mesenchyme. In Platyhelminthes, mesenchyme cells completely fill this space.

In the classification of platyhelminths the principal criteria are: habitat of organism (*i.e.,* free-living or parasitic); the characteristics of the body covering; the form and position of organs for attachment to host (when present); the presence or absence of segmentation; the form of the reproductive system, especially with respect to vitellaria (yolk glands) and the number of testes; the presence or absence of an alimentary canal; the characteristics of the pharynx (when present); and the nature of protective egg membranes.

Annotated classification. There is no unanimity concerning the classification of platyhelminths. The following classification is based partly on that of Grassé, Hyman, Yamaguti, and La Rue (see below *Bibliography*).

PHYLUM PLATYHELMINTHES (flatworms)

Flat, unsegmented worms; gastrovascular cavity and respiratory, skeletal, and circulatory systems absent; excretion by means of flame-bulb protonephridia; mesenchyme fills all spaces between organ systems; a variable number of longitudinal nerve cords with transverse connectives; body structure triploblastic (*i.e.,* 3 embryonic layers); reproductive system hermaphroditic and complex.

Class Turbellaria

Epidermis usually ciliated at least in part, provided with rhabdoids (minute rodlike structures); body unsegmented; gut present except in order Acoela; life cycle simple; mostly free-living, some ectocommensal, endocommensal (*i.e.,* living, respectively, outside or inside another organism without harming it), or parasitic; about 3,000 species.

Order Acoela. Exclusively marine; mouth present; pharynx simple or lacking; no intestine; without protonephridia, oviducts, yolk glands, or definitely delimited gonads.

Order Rhabdocoela. Saclike intestine; protonephridia and oviducts usually present; gonads few, mostly compact; nervous system generally with 2 longitudinal trunks.

Order Alloecoela. Pharynx simple, bulbose or plicate (many ridges); intestine may have short diverticula, or pockets; protonephridia paired; testes usually numerous; penis papilla generally present; nervous system with 3–4 trunks.

Class Monogenea

Oral sucker lacking or weakly developed; posterior end with large posterior adhesive disk (opisthaptor) usually provided with hooks; excretory pores paired, anterior and dorsal; parasites of the skin and other superficial locations, especially on the gills of fish; life cycle simple, no alternation of hosts; about 1,350 species.

Class Aspidocotylea (Aspidobothria)

Oral sucker absent; main adhesive organ occupying almost the entire ventral surface and consisting of suckerlets arranged in rows; excretory pore single and posterior; endoparasites of vertebrates, mollusks, and crustaceans; about 100 species.

Class Cestoda (tapeworms)

Elongated endoparasites with alimentary canal lacking; epidermis modified for absorption and secretion; usually divided into segments (proglottids); adhesive organs limited to anterior end; except in Cestodaria, adult stages almost entirely parasites of vertebrates; life cycles complicated with 1 or more intermediate hosts; about 3,500 species.

Subclass Cestodaria

Unsegmented tapeworms containing 1 set of genitalia; parasites of the body cavity or intestine of annelid worms or fish.

Order Amphilinidea. Uterus long and N-shaped; genital pores at or near posterior extremity; intestinal parasites of teleosts (bony fish).

Order Caryophyllidea. Uterus a coiled tube; genital pore well separated from posterior extremity; intestinal parasites of teleosts, occasionally in annelids.

Order Gyrocotylidea. Testes confined to anterior region; genital pores near anterior end; parasitic in intestine of fish of the genus *Chimaera.*

Subclass Eucestoda

Polyzoic tapeworms with scolex (head) of varying structure; body usually with distinct external segmentation; parasitic in intestine of vertebrates.

Order Tetraphyllidea. Scolex with 4 bothridia (leaflike muscular structure); vitellaria located in lateral margins of proglottids; genital pores lateral; parasites of elasmobranchs.

Order Lecanicephalidea. Reproductive system similar to Tetraphyllidea, but scolex divided into an upper disklike or globular part and a lower collarlike part bearing 4 suckers; mainly parasites of elasmobranchs.

Order Proteocephalidea. Scolex with 4 suckers, sometimes a 5th terminal one; vitellaria located in lateral margins; genital pores lateral; mainly parasites of cold-blooded vertebrates.

Order Diphyllidea. Two bothridia, each sometimes bisected by a median longitudinal ridge; large rostellum (cone-shaped or cylindrical projection) armed with dorsal and ventral groups of large hooks; cephalic peduncle (fleshy stalk on head) with longitudinal rows of T-shaped hooks; genital pore median, parasitic in elasmobranchs; 1 genus, *Echinobothrium.*

Order Trypanorhyncha. Scolex with 2 or 4 bothridia; vitellaria in continuous sleevelike distribution; parasites of elasmobranchs.

Order Pseudophyllidea. Scolex with 2 elongated, shallow bothria, 1 dorsal and 1 ventral; genital pore lateral or median. Vitellaria lateral or extending across proglottid and encircling other organs; parasites of teleosts and land vertebrates.

Order Nippotaeniidea. Scolex bears 1 apical sucker; parasites of freshwater fish; 1 genus, *Nippotaenia.*

Order Cyclophyllidea (Taenoidea). Scolex with 4 suckers; no uterine pores; 1 compact vitellarium behind ovary; mainly parasites of birds and mammals.

Order Aporidea. No sex ducts or genital openings; parasites of swans.

Order Spathebothriidea. Scolex without true bothria or suckers; strobila with internal segmentation but no external segmentation; parasites of marine teleosts.

Class Trematoda (flukes)

Ectoparasites or endoparasites; no ciliated epidermis; body undivided; adhesive organs well-developed; life cycles generally complex with 2 or more hosts, about 6,250 species.

Subclass Aspidogastrea

Oral sucker absent; main adhesive organ occupying almost the entire ventral surface, consists of suckerlets arranged in rows; excretory pore single and posterior; endoparasites of vertebrates, mollusks, and crustaceans.

Subclass Digenea

Oral and ventral suckers generally well-developed; development involves at least 1 intermediate host; usually endoparasites of vertebrates.

Superorder Anepitheliocystidia. Excretory bladder thin walled (*i.e.,* not epithelial in any stage); excretory pores open to exterior in tail; stylet (piercing structure) always lacking.

Order Strigeatoidea. Cercaria (immature form) fork-tailed; penetration glands present; 1–2 pairs of protonephridia.

Order Echinostomida. Cercaria with simple tail and many cyst-producing glands; life cycle with 3 hosts.

Superorder Epitheliocystidia. Cercaria completely lacking caudal excretory vessels at any stage of development; stylet present or lacking.

Order Plagiorchida. Cercaria typically armed with a stylet; encystment in invertebrates, rarely vertebrates; excretory vessels not open to the exterior.

Order Opisthorchiida. Cercaria never armed; excretory pores open on margins of tail.

Critical appraisal. There is disagreement on many aspects of the taxonomy of Platyhelminthes, especially regarding class divisions. Among the free-living or semiparasitic forms, the temnocephalids are placed as an order among the class Turbellaria (as here) by some authorities, but the temnocephalids are treated as a separate class by others. It is now generally recognized that the monogeneans, previously in a class of the Trematoda, are sufficiently divergent from the digeneans, nearer to the cestodes and turbellarians, to be placed in a separate class (Monogenea). The classification of the digeneans used here is based on the development of the excretory bladder and associated structures. Such a scheme, however, clearly raises taxonomic problems of identification for species whose life cycles are not fully known. (J.D.Sm.)

BIBLIOGRAPHY. Classic studies of platyhelminths are LIBBIE HENRIETTA HYMAN, *The Invertebrates,* vol. 2, *Platyhelminthes and Rhynchocoela* (1951); S. YAMAGUTI, *Systema Helminthum* (1958–), taxonomic works with detailed keys—vol. 1 was revised as *Synopsis of Digenetic Trematodes of Vertebrates* (1971); and "Plathelminthes, mésozoaires, acanthocéphales, némertiens," in P.P. GRASSE (ed.), *Traité de zoologie,* vol. 4 (1961). NATHAN W. RISER and M. PATRICIA MORSE (eds.), *Biology of the Turbellaria* (1974), provides more current information. Collections of papers examining various aspects of turbellarians are found in ERNEST R. SCHOCKAERT and IAN R. BALL (eds.), *The Biology of the Turbellaria* (1981); and PETER AX, ULRICH EHLERS, and BEATE SOPOTT-EHLERS (eds.), *Free-Living and Symbiotic Plathelminthes* (1988). BEN DAWES, *The Trematoda* (1946, reissued 1968), is a classic work but somewhat out-of-date; it may be updated by two newer works, DAVID A. ERASMUS, *The Biology of Trematodes* (1972); and J.D. SMYTH and D.W. HALTON, *The Physiology of Trematodes,* 2nd ed. (1983), a detailed monograph for students. Also useful is G.R. LA RUE, "The Classification of Digenetic Trematoda: A Review and a New System," *Experimental Parasitology,* 6:306–344 (1957). Cestodes are examined in ROBERT A. WARDLE and JAMES ARCHIE MCLEOD, *The Zoology of Tapeworms* (1952, reissued 1968), a classic work, largely taxonomic, but somewhat out-of-date; J.D. SMYTH, *The Physiology of Cestodes* (1969), a detailed study for students; ROBERT A. WARDLE, JAMES ARCHIE MCLEOD, and SYDNEY RADINOVSKY, *Advances in the Zoology of Tapeworms: 1950–1970* (1974); and J.D. SMYTH and D.P. MCMANUS, *The Physiology and Biochemistry of Cestodes* (1989). Guides to identification include IAN R. BALL and T.B. REYNOLDSON, *British Planarians, Platyhelminthes, Tricladida* (1981); and GERALD D. SCHMIDT, *CRC Handbook of Tapeworm Identification* (1986).

Florence

A former republic, a former seat of the duchy of Tuscany, and a former capital of Italy, Florence (Italian: Firenze; Latin: Florentia) lies almost at the centre of the Italian peninsula, some 145 miles (230 kilometres) northwest of Rome. Today it is the capital of Firenze province, covering an area of about 40 square miles (104 square kilometres). The city is surrounded by gently rolling hills that are covered with villas and farms, vineyards and orchards.

The present glory of Florence is mainly its past. Its buildings are works of art abounding in yet more works of art. The splendours of the city are stamped with the personalities of the men who made them. The geniuses of Florence were backed by men of towering wealth, and the city to this day gives testimony to their passions for religion, for art, for power, or for money. Among the most famous of the city's giants are Leonardo da Vinci, Michelangelo, Dante, Machiavelli, Galileo, and its most renowned rulers, the generations of the Medici family.

Scholars still marvel that this small city of moneylenders and cloth-makers without much political or military power rose to a position of enormous influence in Italy, Europe, and beyond. The Florentine vernacular became the Italian language; and the local coin, the florin, became a world monetary standard. Florentine artists formulated the laws of perspective; Florentine men of letters, painters, architects, and craftsmen began the period known as the Renaissance; and a Florentine navigator, Amerigo Vespucci, gave his name to two continents.

This article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

The city site. Florence was founded to control the only practicable north-south crossing of the Arno River to and from the three passes through the Apennines: one to Faenza and two to Bologna. Two thin streams, the Mugnone and the Affrico, come down through town to meet the Arno. The Affrico, not far away from its source in the Apennines, is usually a grudging gurgle amid wide gravel beds far below the quays, but sometimes it rises and swells into a powerful stream, ravaging the city with floods. The city's water supply, however, has also served as an asset, making possible the washing, fulling, and dying of cloth, resulting in the development of a major industry.

Florence's position as a major crossroads between Bologna and Rome made the city vulnerable to attack. Its hills offered some protection, but the citizens nonetheless felt compelled to erect imposing walls during the period 1285–1340; although the walls were largely torn down during urban expansion in the 1860s, their former presence remains clearly visible in a girdle of roads around the original city. Moreover, because the hillier south bank of the Arno has prevented urban growth, segments of the walls are preserved.

Beyond the historic centre of Florence, the city has expanded over the past century to accommodate waves of migration. Vast modern housing projects have been constructed, such as those at Isolotto (1954–55). These peripheral zones have actually grown to dominate the city centre, creating a kind of "open urban system"—and a vast and successful industrial district—that stretches northwest to Prato and southeast as far as Arezzo. Huge satellite towns such as Scandicci have grown to rival the centre of Florence itself.

The climate. Florence's location in a small basin encircled by hills is a determining factor for its changeable climate. Summers tend to be extremely hot and humid, and winters cool and wet. The average monthly temperature for July and August is about 73° to 75° F (23° to 24° C), with an average daytime high of about 95° F (35° C); the average monthly temperature for January is 41° F (5° C). Yet winters tend to be short-lived, ending generally in mid-March, and bring rain rather than snow. Unpleasantly cold showers can, however, persist into April, much to the discomfort of the throng of Easter tourists. The most delightful seasons in which to visit Florence are late spring and fall, when the sky becomes an azure vault and the sun warms but does not scorch.

The city layout. Although most of the city of Florence was a creation of the nascent Renaissance era, the city's Roman beginnings as a typical *castrum,* or garrison town, can still be perceived. They are visible in the rectilinear grid whose axis is the Via Calimala, with a forum in today's Piazza della Repubblica (used as a market during most of its history). The skyline, however, is dominated by two imposing structures of later centuries. One of them is the austere tower of the Palazzo Vecchio (Old Palace), begun in 1299, in the Piazza della Signoria. It housed the legislative and executive branches of the local civic government (the priors) and even today functions as the town hall of Florence. Always a kind of nerve centre of local pride and power, the building was ornamented with major works of Florentine sculpture; foremost among these was Michelangelo's towering statue of "David" (today replaced by a copy). Also framing the Piazza della Signoria is the elegant Loggia dei Lanzi, built in the late 14th century; today it serves as an open-air museum for masterworks of sculpture, including Benvenuto Cellini's "Perseus."

Roman beginnings

From behind the loggia and from the flank of the palazzo, the tall, colonnaded, twin wings of a later building, the Uffizi, stretch down to the Arno. An elegant edifice designed by Giorgio Vasari, it was begun in 1560 to house the grand ducal offices. In 1574 Grand Duke Francesco I ordered the top story converted to display the Medici art treasures. The Uffizi's collection, one of the most precious in the world, offers examples of painting from the 13th century through the 18th and includes most of the significant names in Florentine art.

Duomo and campanile

The second distinctive feature of Florence's skyline is the dome of the cathedral (Duomo), Santa Maria del Fiore. The building itself, located due north of the Piazza della Signoria, was begun by the sculptor Arnolfo di Cambio in 1296. Numerous local artists continued to work on it during the following century and a half. The painter Giotto designed its sturdy bell tower (campanile) in 1334. Yet, the massive octagonal cupola (1420–36) that truly dominates

Florence and (inset) its metropolitan area.

both the church and the city was the proud achievement of Filippo Brunelleschi, master architect and sculptor. Opposite the cathedral stands the Baptistery; the building dates from the 11th century but was believed by Florentines to be a surviving Roman monument when they commissioned for it a series of bronze doors with relief sculptures (1330; 1401–52). The third pair of these doors, by Lorenzo Ghiberti, were of such rare beauty that Michelangelo christened them the "Gates of Paradise."

Around the perimeters of historical Florence lie the vast "newcomer" churches of the mendicant orders: to the west, Santa Maria Novella (begun 1279) of the Dominicans; to the east, Santa Croce (begun 1294) of the Franciscans. Each of these churches is a monument of Renaissance art in its decoration. The interior of Santa Maria Novella contains the Spanish Chapel, with frescoes by Andrea da Firenze; the Green Cloister, with frescoes by Paolo Uccello; the Strozzi Chapel, with frescoes by Filippino Lippi; and the Cappella Maggiore, with frescoes by Domenico Ghirlandaio, in addition to Masaccio's awe-inspiring fresco "The Trinity," with its fully realized use of perspective. The facade of Santa Maria Novella was completed (1456–70) by the design of Leon Battista Alberti. Alongside Santa Croce, Brunelleschi appended the Pazzi Chapel, designed geometrically around the motif of a circle within a square. Inside Santa Croce one finds major fresco cycles by the most famous early Florentine painter, Giotto. Paradoxically, the patrons of this church were among the richest families of Florence, despite (or perhaps because of) the vows of poverty sworn by the Franciscan order. Santa Croce has historical significance as well, because it became a kind of pantheon containing the tombs of famous Florentine scholars, writers, artists, and patriots. Across the Arno lies the modest Carmelite church of Santa Maria del Carmine, whose Brancacci Chapel displays some of the most powerful early 15th-century frescoes by Masaccio and Masolino (*c.* 1425–27).

Between the Piazza della Signoria and the cathedral lies a remarkable building, the Orsanmichele (oratory of St. Michael). In 1290 Arnolfo built a loggia here for the wheat market, which, however, was destroyed by fire; a larger loggia was erected in 1377 and then enclosed to form a church in 1380. Its chief fame comes from its early 15th-century decoration donated by the major guilds of Florence. Each guild was assigned one of the tabernacles on the exterior of the Orsanmichele and expected to commission a sculpture for it. The best works produced include bronzes of St. John the Baptist (patron of the city and of the Calimala guild) and St. Matthew (for the Cambio, or bankers) by Ghiberti and marbles of St. Mark (linen drapers) and St. George (armourers) by Donatello.

North of the cathedral lay the province of the eventual

rulers of Florence, the Medici, a family of bankers. On the square behind the house of the Medici stands the Augustinian church of San Lorenzo, for which Brunelleschi made an austerely simple geometric Renaissance design based on his study of early Christian basilicas in Rome (1421). Medici patronage led to decisive artistic decorative additions. Donatello provided a bronze pulpit, and Brunelleschi added a sacristy (the Old Sacristy); about one century later Michelangelo balanced it with the New Sacristy, which contains his famous Medici Tombs. Michelangelo also designed the Laurentian Library, next to San Lorenzo, to house the great library assembled by the Medici family. Near the church sits the Medici Palace, built by the architect Michelozzo beginning in 1444. Inside, a chapel contains a fresco by Benozzo Gozzoli depicting the "Procession of the Magi" (1459), in which the followers of the Magi are given features of the Medici.

The Strozzi Palace

The grandest palace in Florence is the Strozzi Palace, begun in 1489 for one of the city's largest and wealthiest families (which, however, had been eclipsed politically by the Medici). Its enormous scale deliberately surpassed that of the Medici Palace. Noteworthy within the Strozzi Palace is a spacious courtyard, which by its use of arches and a loggia achieves a feeling of openness and simplicity.

South of the Arno lies the Pitti Palace; this grandiose structure was created for the grand duke Cosimo I by the sculptor Bartolommeo Ammannati, who extended (1558–70) a palace belonging to the Pitti family of a century earlier. The hills behind this massive palace were transformed into magnificent gardens, the Boboli Gardens, filled with fountains, statues, and an amphitheatre; here operas and concerts for the Medici rulers betokened their courtly existence as the absolute rulers of the city. Ammannati also designed a bridge to the palace, the Santa Trinità Bridge (1567–69; restored).

THE PEOPLE

Florence's greatest poet, Dante, harshly characterized his city's people as tightfisted, envious, and haughty. A touch of this severe judgment still clings to the Florentines, in whose makeup one tends to miss the exuberance and warmth associated with Italians in other towns and regions. Perhaps the Florentines, many of whom are descendants of long lines of Florentines, are reserved in self-defense against the massive stream of tourists; every year about two and a half million visitors crowd the historic sections of Florence, filling the air with foreign tongues.

The city's population increased significantly during the 20th century. Immigrants before the 1970s were mainly from the Tuscan region but also from the south of Italy. Many Chinese actually had arrived earlier, and since the mid-1970s the city and its region have attracted other people from outside Italy who found work in the area's tourist-linked service economy. These immigrants have begun to change the cultural makeup of the city. Indeed, some of the first explosions of racial animosity in Italy took place in Florence in the early 1990s, when Italian locals organized raids on immigrant street vendors, which led to a national debate over immigration.

THE ECONOMY

Industries. Thousands of Florentines work in industrial suburbs, where they are engaged in the production of furniture, rubber goods, chemicals, and food. Yet the city lives primarily from tourism and from the traditional handicrafts—glassware and ceramics, wrought iron, leatherwork, wares of precious metals, art reproductions, and the like—with some high-fashion clothing and shoe production. Key fashion companies operating in the city include Gucci and Ferragamo. Florence hosts numerous fairs throughout the year, including an international antiques fair, international fashion shows, and countless artisans' exhibits. Commercial and cultural interests blend in the city's offerings of festivals of music, opera, and the visual arts. In particular, the annual Maggio Musicale ("Musical May" festival) attracts visitors from far beyond the city. Of special appeal are the traditional festivals, many of them resplendent with the trappings of medieval pageantry and procession. Among the more famous ones are the celebrations in honour of the city's patron saint, St. John the Baptist. Visitors can watch the fireworks on June 24 (St. John's Day) or attend the "football game" staged in 16th-century costumes in the Boboli Gardens during St. John's Week.

The merchants of Florence

Craftwork is sold throughout the city, but several traditional marketplaces still exist. The vendors of straw objects—from tiny figurines to full-sized dresses—have their stalls in the Loggia of the Mercato Nuovo (New Market, built in 1547–51). Goldsmiths, silversmiths, and jewelers are concentrated on the Ponte Vecchio, one of the world's most famous bridges and the symbol of Florence. They opened for business there in the 16th century, when Grand Duke Ferdinand I deemed it inelegant for butcher shops to line the bridge as they had for the previous 200 years. He ordered practitioners of the "vile arts" to give way to workers in precious metals. The new occupants eventually enlarged their shops by building outward over the water, propping their three-story additions on brackets from the bridge. The back elevations of these extensions give the bridge its picturesque air. Above the shops a covered passage was constructed in 1564–65 to connect Cosimo's palace (the Pitti Palace) on the left bank with the newly erected government offices (the Uffizi) on the right bank.

Artisans who fashion the gold, silver, jewelry, straw, intarsia (inlaid woodwork designs), leather goods, glass, pottery, and embroidery complain of being squeezed out of existence by the pressures of modern economic life. These artisans can, however, still be seen through the open doors of their workrooms, engaged in the tasks and poised in the attitudes shown in the carvings on the 15th-century facade of the guildsmen's church, Orsanmichele.

Traditional heavy industry is still important in the area. Major employers include Nuovo Pignone (now part of the American General Electric Company), maker of steam turbines and compressors, and Piaggio & Company (located in and around Pisa, 50 miles to the west), maker of the famous Vespa scooter. The city is now part of a huge industrial district running northwest to Prato and Pistoia. This zone, with its small businesses and quality export production, was one of the centres of the prosperous "third Italy" of the 1990s, rivaling similar zones in Emilia-Romagna and Veneto in employment and profits. Hundreds of thousands of former sharecroppers from rural areas of Tuscany have become small businessmen in a single generation, avoiding the trauma of "normal" rapid industrialization. However, the environment has suffered as the beautiful Tuscan countryside has slowly been urbanized and as motor-vehicle traffic has threatened to suffocate not just the city but the entire region.

Transportation. In the central area of Florence a solid pair of walking shoes is the best mode of transportation, especially since the historic section has been closed to motor vehicles. Buses and taxis are also available, as are bicycles for hire. The main highway, the Autostrada del Sole, passes west and south of the city. Because Florence lies on the country's main north-south train line, rail connections are highly dependable and efficient. The Eurostar connects Florence with Milan in less than three hours and with Rome in less than two. In addition, Florence has its own airport, Amerigo Vespucci (formerly Peretola), only three miles from the city centre. It is too small for intercontinental traffic, but Pisa's Galileo Galilei International Airport is an hour's train journey away.

CULTURAL LIFE

Florence has numerous museums, mostly devoted to painting and sculpture. The National Central Library (Biblioteca Nazionale Centrale) has been the Italian library of deposit since 1870, receiving a copy of every book published in the nation. It houses millions of autographs, manuscripts, letters, incunabula, and books, including many rare editions. The Riccardiana and Moreniana libraries adjoining the Palazzo Medici-Riccardi have the most complete collection, including valuable manuscripts, of works on Tuscan history. The Gabinetto Scientifico e Letterario G.B. Vieusseux is a scientific and literary library founded in 1819 by Jean-Baptiste Vieusseux, who was the central figure of a group that included the leading literary figures of Italy at that time.

Universities and learned institutions

After Lorenzo de' Medici transferred the University of Florence (founded 1349) to Pisa in 1472, the medical school remained behind, leading the scientific movement in Italy and forming the nucleus for the university that was legally constituted only in 1923. The Academy of the Crusca was established in 1582 to prepare an Italian dictionary; *crusca* means "bran," the academy's symbol is a sieve, and its object remains to winnow impurities from the language. Other specialized learned institutions include an observatory; academies of fine arts, science, letters, and agrarian economics; and institutes of Etruscan and Italian studies, of the history of art, and of the history of optics. The Italian Dante Society, the Italian Botanical Society, and the Society for Geographical Studies are in Florence.

An increasing number of foreign nations and universities conduct study institutes in Florence. The Harvard University Center for Italian Renaissance Studies is located at the exquisite Villa i Tatti, bequeathed by the art historian Bernard Berenson, in the hills at Settignano. The Universities of Grenoble (Fr.) and Paris, Syracuse University (N.Y., U.S.), Stanford University (Palo Alto, Calif., U.S.), Smith College (Northampton, Mass., U.S.), universities of The Netherlands, and the U.S. state universities of California are represented.

The glory of many Florentines is the city's football team, Fiorentina—or "la Viola," as the team is affectionately called, owing to the players' purple shirts. The club has won the Italian championship on only two occasions (in 1956 and 1969), but it continues to inspire fanatic support from its followers. When star Roberto Baggio was sold to archrival Juventus of Turin in 1990, Fiorentina supporters caused riots that paralyzed the city. The stadium, originally designed in the 1930s by modernist architect Pier Luigi Nervi, has achieved national monument status. It was refurbished for the 1990 World Cup and renamed the Stadio Comunale "Artemio Franchi," or simply Franchi Stadium.

History

THE EARLY PERIOD

Founding and growth. Florentia ("The Flourishing Town") was founded in 59 BC as a colony for soldiers of the armies of Rome and was laid out as a rectangular garrison town (*castrum*) below the hilltop Etruscan town of Faesulae. Its streets formed a pattern of rectangular blocks, with a central forum, a temple to Mars, an amphitheatre, and public baths. By the 3rd century AD Florence was a provincial capital of the Roman Empire and a prosperous commercial centre. During the early medieval centuries, Florence was occupied chiefly by outsiders: first by Ostrogoths in the 5th century, then by Byzantines in the 6th century, and eventually by Langobards, or Lombards. From the late 10th century onward Florence prospered, and, under the rule of Countess Matilda of Tuscany (1069–1115), it became the leading city in Tuscany.

In 1293 Florence adopted a constitution called the Ordinances of Justice, which barred both the nobility and labourers from political power. It also provided for frequent changes of office to ensure that no group or individual could get control of the state; thus the nine priors who constituted the Signoria (the governmental body) were each elected for a mere two months. As a result, Florentines developed a keen interest in their politics and became a community of civil servants available for public life; but the lack of continuity often provoked factional intrigues and alliances.

Growing economic and political power

During the 12th and 13th centuries the economic and political power of the city grew steadily. The rise of the Florentine woolen cloth industry and of banking provided a basis of capital. Then the resolution in 1266 of a bitter strife between two internal factions oriented respectively toward papal (Guelf) and imperial (Ghibelline) protection resulted in victory for a group of Guelf merchant families in the city (as well as the exile in 1302 of Florence's greatest poet, Dante Alighieri). They took over papal banking monopolies from rivals in nearby Siena and became tax collectors for the pope throughout Europe. From such a foundation, Florentine families, led by the Bardi and the Peruzzi, came to dominate both banking and international merchant business. Locally, Florence also added neighbouring cities to its sphere of influence and obliged rival powers—Pisa, Siena, Pistoia, and Arezzo—to become its allies.

With a balance between its leading merchant families, Florence was now ruled by its guilds, divided into seven major guilds and a number of minor ones. The city's *podesta,* or chief magistrate and police chief, could be selected only from the major guilds. Political parties grew up along the issues of aggressive expansion and preservation of peace; the former policy was embraced by the Blacks (Neri; the rich merchants), the latter by the Whites (Bianchi; the lesser citizens).

Just before the middle of the 14th century, Florence had become a metropolis of about 90,000 people, making it one of the great cities of Europe (alongside Paris, Venice, Milan, and Naples). However, in the summer of 1348 the Black Death struck, reducing the population by half. The city's ordeal during this period has been vividly portrayed by the chronicler Matteo Villani and by the writer Giovanni Boccaccio in the preface to his stories of the *Decameron.* The bankruptcies of the Bardi and the Peruzzi a few years before the Black Death had already shaken the city's prosperity, and it never fully recovered from these double disasters. Famine and renewed bouts of the plague continued throughout the 14th century, sparking unrest among the politically unrepresented population. In 1378 a proletarian rebellion of the cloth workers, the Ciompi revolt, was put down by an alliance of merchants, manufacturers, and artisans. The economy of the city remained depressed, and the rivalry of adjoining polities, first Milan and then Naples, only intensified the threats to Florence's prosperity in the early 15th century. One of the few successes was the conquest of Pisa in 1406, making Florence a maritime power at last. Partly in self-defense, Florence became a major territorial power alongside Venice, Milan, and Naples.

During this period of adversity, the power of the guilds and their domination of the city were on the wane; as a result, successful merchants and bankers, chiefly Cosimo de' Medici and Giovanni Rucellai in the 15th century, were able to shape civic politics and culture through a system of oligarchy and patronage. They underwrote the accomplishments that are now singled out with the term "Renaissance," and their palaces came to dominate the city as fully as the church buildings in which they established their family chapels.

The rule of the Medici. Cosimo de' Medici (Cosimo the Elder; d. 1464) became the leading citizen in Florence after his return in 1434 from a year of exile. He achieved this position by virtue of his great wealth (the result of the largest banking network in Europe) and an extensive network of patronage obligations. While he never accepted public office, his faction dominated the city. He lived an increasingly opulent life, as is apparent in the ostentation of the Medici Palace and the patronage of churches such as San Lorenzo and the Monastery of St. Mark, with its frescoes by Fra Angelico. Investment in culture, including the patronage of artists and architects and the purchase of books and manuscripts, became a fundamental expression of the Medici's aristocratic way of life; it was continued by Cosimo's son, Piero, and his grandson, Lorenzo (d. 1492; dubbed "the Magnificent"). In all but name, Florence was now ruled by a Medici prince, whose position resembled that of the tyrants in other Italian cities such as Milan, Ferrara, Mantua, and Urbino.

Girolamo Savonarola

Stability was briefly threatened in 1478 by the brutal but abortive Pazzi conspiracy seeking to end the Medici rule. In 1494, shortly after the death of Lorenzo, French armies under King Charles VIII invaded Italy. They were backed against the Medici by the popular party in Florence, which (with French help) succeeded in exiling the Medici and declaring Florence a republic. The consequence, however, was the loss of political autonomy to the larger conflicts of Italian peninsular struggles. Republican Florence was led briefly by a fiery Dominican preacher, Girolamo Savonarola, who boldly condemned the luxury and urbane culture of his predecessors. His strict rule came to an end in 1498, but with it closed a phase of Florentine greatness.

The Medici returned to Florence in triumph in 1512 behind the papal and Spanish armies, reasserting power in a clear and ruthless manner. (Such an unambiguous pursuit of power by leaders at this time was given codification in 1513 by Niccolò Machiavelli in his treatise *The Prince.*) In addition, the younger son of Lorenzo was elected Pope Leo X; his pontificate (1513–21) was noteworthy for its cultivation of the arts, especially his employment of Raphael. Leo was shortly followed by another Medici pope, Clement VII (1523–34). However, in 1527 the riotous Spanish army of Emperor Charles V overran Rome, and during this moment of weakness republicans again expelled the Medici from Florence, only to be punished in 1530, when pope and emperor were reconciled. Then in 1536 the statesman and historian Francesco Guicciardini began to compose his *History of Italy,* with its ideal vision of the era of Lorenzo the Magnificent and its pessimism concerning more recent events. In 1537 Charles V installed Cosimo de' Medici (Cosimo I; d. 1574) as official duke of Florence (grand duke of Tuscany after 1569). Cosimo and his wife, Eleonora of Toledo, patronized the arts and undertook vast building programs, such as the construction of the Uffizi, the renovation of the Palazzo Vecchio, and the reconstruction of the Pitti Palace.

With the rise of Cosimo I to titled nobility and to absolute rule in Florence, the political and cultural vitality of the city had all but ebbed, prompting a modern scholar to refer to the succeeding era as the "forgotten centuries." Florence's dukes had become minor players in the broader European balance of great powers, and they linked themselves chiefly with the noble houses of France. Marital alliances of Medici family members with members of the French nobility include Catherine de Médicis (d. 1589), queen of Henry II and later regent of France; Grand Duke Ferdinand I (d. 1609), who married Christine of Lorraine; and Marie de Médicis (d. 1642), who married King Henry IV of France. The city generally declined under prolonged Medici rule, a process that was marked only by the extended reign of Cosimo III (1670–1723) and the end of the family with the death of his son, Gian Gastone (d. 1737).

From outside rule to unification. After the rule of the Medici, Florence was governed from outside, as Francis Stephen of Lorraine, the husband of Empress Maria Theresa of Austria, became the grand duke of Tuscany. Following a Napoleonic interlude, Leopold II of Habsburg was the last outside ruler (1824–59). He eventually abdicated in favour of the new Italian king, Victor Emmanuel. In 1860 Florence annexed itself to the new kingdom of Italy, serving as its capital during the period 1865–70.

From the late 18th to the mid-20th century, a large Anglo-American colony was an integral part of the Florentine scene. The poet Elizabeth Barrett Browning, who is buried in the small English cemetery, noted that the city was "cheap, tranquil, cheerful and beautiful." The Horne Museum, near Santa Croce, and the Stibbert Museum, in the north, are examples of houses and collections left by foreigners to their adopted city.

EVOLUTION OF THE MODERN CITY

Human and natur despoliation

During the decades after unification, much of Florence's past was seriously jeopardized as a huge debate surrounded the renewal of the city. Many of its finest structures were altered or defaced, its medieval walls were largely pulled down, and its ancient centre was laid waste as entire zones were cleared and replaced with squares and other public spaces. Florence's brief period as Italy's capital in 1865–70 saw a vast increase in the city's population. Growth continued chaotically into the 20th century, when order and sense were slowly restored to the renovations.

Florence was occupied by the German army in the latter stages of World War II. Antifascist resistance was very strong in the city and Tuscan region, and fighting was heavy. On leaving Florence, the Germans blew up all the bridges across the Arno but spared the famous Ponte Vecchio. After the war, debates again arose regarding the reconstruction of the city. The 1950s saw Florence expand into its periphery, and in 1962 a plan was developed partly to guide expansion away from the Florence-Prato conurbation. Despite certain innovative qualities, the plan failed, and the two cities are now all but one, constituting one big urban sprawl. The population of Florence reached more than 400,000 in the 1980s but soon fell slightly below that level.

In addition to human despoliation, nature has been an occasional adversary of Florentine life, mainly in the form of floods of the Arno. The city's bridges were destroyed in the 12th century and again in 1333. In 1557 the Ponte Vecchio held fast, but the others were destroyed. The most devastating occurrence was the flood of November 1966. The city's cultural heritage was grievously damaged by waters coursing through the streets and swirling into buildings, depositing debris, mud, and oil. Major public works took place to try to ensure that there would be no repetition of this tragic event. Despite some scares, the Arno has not burst its banks since then.

Since the mid-20th century, Florence has been governed largely by centre-left administrations that have been known for their reformist zeal, honesty, and efficiency (with some notable exceptions). Through the popular mayor Giorgio La Pira, left-wing Catholics were able to run the city for a number of years in the late 1950s and early 1960s. Since then the subcultures of the left have survived in Florence, despite their erosion elsewhere in Italy, and the old Italian Communist Party, now known as the Partito Democratico di Sinistra (Democratic Party of the Left), has managed to maintain a strong presence as well. With its large university population and radical-left traditions, Florence was one of the centres of student and worker revolts in 1968.

In the 1980s and 1990s, the main problems of the city were environmental. The huge influx of tourists threatened to swamp the city in every sense, and the city centre began to lose its distinctive character and its artisan workshops. Pollution reached record levels, thanks to mass ownership of motor vehicles and to the peculiar geographic position of the city. Drastic measures were finally taken in the 1980s with the closure of the city centre to private cars. This policy has gone some way toward alleviating pressure on the city, but the area is still suffocated by thousands of scooters and buses, and the city still endures a constant tourist onslaught. Florence faces the danger of becoming a commercialized provincial town, full of trinket shops, overpriced bars, and crowded museums. Certainly the dynamic economic district running across to Prato is not matched by the city itself, which continues to capitalize on the past. The label of "museum-city" is thus perhaps best applied to the Florence of today, despite the highly productive region of which it is the capital.

BIBLIOGRAPHY

General works. Numerous guides to the city are published every year, most of them repeating basic information. A useful example is PAOLO DE SIMONIS *et al.*, *Florence: A Complete Guide to the Renaissance City, the Surrounding Countryside, and the Chianti Region,* trans. from Italian by ANTONY SHUGAAR (1999), in the *Heritage Guide* series. An excellent guide to architecture in the city can be found in *Architectural Guides: Florence,* 2nd ed. (1998), in the *Allemandi's Architectural Guides* series. A more scholarly work is GUIDO ZUCCONI, *Florence: An Architectural Guide* (1995). ALTA MACADAM, *Florence,* 8th ed. (2001), in the *Blue Guide* series, provides a general introduction to Florence and its history as well as maps and tours of different sections of the city. MARY McCARTHY, *The Stones of Florence* (1959, reissued 1987), offers a more evocative and literary survey. A useful Italian guide is ADRIANO AGNATI (ed.), *Firenze: le colline, il Mugello, il Valdarno, il Chianti* (1994), published by Touring Club Italiano.

History. Not surprisingly, most histories of Florence focus on the origins and developments of the Renaissance era, particularly the 14th and 15th centuries. The early era of civic greatness is explored in GEORGE HOLMES, *Florence, Rome, and the Origins of the Renaissance* (1986, reissued 1989). The city received its own 16th-century history at the hands of one of its greatest political thinkers, NICCOLÒ MACHIAVELLI, *History of Florence and of the Affairs of Italy: From the Earliest Times to the Death of Lorenzo the Magnificent* (1994; originally published in Italian, 1532), available in many printings. Shortly afterward this account was complemented by the authority of FRANCESCO GUICCIARDINI, *The History of Florence* (1970; trans. from Italian, 1931; originally published in 1859). The historiography of both chroniclers is the subject of FELIX GILBERT, *Machiavelli and Guicciardini: Politics and History in Sixteenth-Century Florence* (1965, reprinted 1984); supplementing that is GISELA BOCK, QUENTIN SKINNER, and MAURIZIO VIROLI (eds.), *Machiavelli and Republicanism* (1990, reissued 1993). An introduction to Machiavelli is available in QUENTIN SKINNER, *Machiavelli: A Very Short Introduction,* rev. ed. (2000).

An impressive analysis of social and economic conditions, as well as of the political situation, is presented in GENE BRUCKER, *Florentine Politics and Society, 1343–1378* (1962), *Renaissance Florence* (1969, reprinted 1983), and *The Civic World of Early Renaissance Florence* (1977); and GENE BRUCKER (ed.), *The Society of Renaissance Florence: A Documentary Study* (1971, reissued 1998). Issues of daily life (and death) are discussed in C.C. BAYLEY, *War and Society in Renaissance Florence: The De Militia of Leonardo Bruni* (1961); KATHARINE PARK, *Doctors and Medicine in Early Renaissance Florence* (1985); and DANIEL R. LESNICK, *Preaching in Medieval Florence: The Social World of Franciscan and Dominican Spirituality* (1989). More on economic and social conditions is in RICHARD A. GOLDTHWAITE, *The Building of Renaissance Florence: An Economic and Social History* (1980, reissued 1990); and CHRISTIANE KLAPISCH-ZUBER, *Women, Family, and Ritual in Renaissance Italy,* trans. from French (1985, reissued 1987), the latter emphasizing Florence's female population. Developments in public culture are observed in RICHARD C. TREXLER, *Public Life in Renaissance Florence* (1980, reissued 1991). Neglected post-Renaissance developments are discussed in the aptly titled ERIC COCHRANE, *Florence in the Forgotten Centuries, 1527–1800: A History of Florence and Florentines in the Age of the Grand Dukes* (1973). Other aspects are explored in JEAN-CLAUDE WAQUET, *Corruption: Ethics and Power in Florence, 1600–1770* (1991; originally published in French, 1984).

A more recent history by SIDNEY TARROW, *Democracy and Disorder: Protest and Politics in Italy, 1965–1975* (1989), covers events of 1968, in particular at Isolotto. Italian books on the development of Florence in the 20th century are LAURA CERASI, *Gli ateniesi d'Italia: associazioni di cultura a Firenze nel primo Novecento* (2000); CARLO CRESTI, *Firenze, capitale mancata: architettura e città dal piano Poggi a oggi* (1995); GIORGIO MORI (ed.), *La Toscana* (1986); and GIORGIO SPINI and ANTONIO CASALI, *Firenze* (1986).

Art. Florentine artists are the chief heroes in the later 16th-century history of Italian art by GIORGIO VASARI, *Lives of the Most Eminent Painters, Sculptors & Architects,* trans. by GASTON DU C. DE VERE, 10 vol. (1912–15, reprinted 1976; originally published in Italian, 3 vol., 1550); and much detail on the same period emerges from an artistic autobiography by BENVENUTO CELLINI, *The Life of Benvenuto Cellini,* trans. by JOHN ADDINGTON SYMONDS (1995; originally published in Italian, 1728), available in many printings. Many general histories of Italian Renaissance art devote considerable space to Florentine developments, with some giving special emphasis to the city alone. Outstanding among these is MARTIN WACKEMAGEL, *The World of the Florentine Renaissance Artist: Projects and Patrons, Workshop and Art Market,* trans. by ALISON LUCHS (1938, reissued 1981; originally published in German, 1938); it can be supplemented by the more argumentative FREDERICK ANTAL, *Florentine Painting and Its Social Background: The Bourgeois Republic Before Cosimo de' Medici's Advent to Power, XIV and Early XV Centuries* (1948, reprinted 1986); and the more general study of the arts in PETER BURKE, *The Italian Renaissance: Culture and Society in Italy,* 2nd ed., rev. (1999). The chief pictorial handbook remains BERNARD BERENSON, *Italian Pictures of the Renaissance: A List of the Principal Artists and Their Works, with an Index of Places: Florentine School,* 2 vol. (1963). Frescoes are the subject of EVE BORSOOK, *The Mural Painters of Tuscany: From Cimabue to Andrea del Sarto,* 2nd ed., rev. and enlarged (1980). WALTER PAATZ and ELISABETH PAATZ, *Die Kirchen von Florenz,* 6 vol. (1952–55), is an informative work on churches. Sculpture is covered in JOHN POPE-HENNESSY, *An Introduction to Italian Sculpture,* 4th ed., 3 vol. (1996, reissued 2000); and CHARLES SEYMOUR, *Sculpture in Italy: 1400–1500* (1966). An appreciation of a high point of Florentine painting is offered in S.J. FREEDBERG, *Painting of the High Renaissance in Rome and Florence,* new rev. ed., 2 vol. (1985); and ANDRÉ CHASTEL, *The Flowering of the Italian Renaissance,* trans. from French (1965). Art in its intellectual or phenomenological context is discussed in MICHAEL BAXANDALL, *Giotto and the Orators: Humanist Observers of Painting in Italy and the Discovery of Pictorial Composition, 1350–1450* (1971, reprinted 1986), and *Painting and Experience in Fifteenth-Century Italy: A Primer in the Social History of Pictorial Style,* 2nd ed. (1988). (B.E./L.A.Si./J.Ft.)

Folk Arts

Applications of the term folk have become problematic. On the face of it, the word has a simple definition—*i.e.,* "the common people, especially those of rural areas." But, like all class distinctions, "folk" carries with it the complications of historical context and point of view. Such a designation formerly implied a high degree of cultural insularity, but mass culture has since penetrated virtually every social and geographic area of the industrial world. Romantic and often patronizing views of folk life have further distorted popular perceptions. A relative and subjective concept like "folk," while academically useful, resists a consensus of interpretation. Anthropologists and folklorists have classified as "folk art" a broad range of materials, from the arts of the so-called primitive or nonliterate peoples to those of the nonelite within literate cultures, the latter variously known as folk, visionary, outsider, or naive. The folk art rubric has also been extended to include all manner of traditional or nostalgic artistic productions, even the self-consciously quaint.

For the purposes of this article, the folk arts may be considered to encompass the traditional, typically anonymous arts produced by members of a nonruling, relatively nonaffluent, often rural and uneducated stratum of industrial society. As expressions of community life, the folk arts are distinguished from the academic or self-conscious or cosmopolitan expressions that constitute the fine arts and decorative arts of the elite. As nonrepresentative of their respective societies as a whole, they are distinguished from the arts of nonliterate cultures. They are also to be differentiated from the so-called popular arts, which appeal to a mass audience and typically depend upon the mass media for their dissemination.

While in popular usage the term folklore refers almost exclusively to a single aspect of folk art, the oral literary tradition, scholars use it to embrace all of the artistic genres of folk culture. In the context of this article the terms folklore and folk art are interchangeable. The first part of this discussion treats folklore as an academic field, viewed from humanistic, anthropological, and psychological perspectives. The functions of folklore and the role of the folk artist, as interpreted from these viewpoints, are also examined. The remainder of the article considers the origins, formal characteristics, and distribution of the various genres of folk art: oral literature, music, dance, and the products of material culture (*i.e.,* the visual arts). (Ed.)

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 613, 621, 622, and 624–629, and the *Index.*

The article is divided into the following sections:

Folklore as an academic discipline

No field of learning is perhaps more misunderstood than folklore. The public, and many academics, do not know that folklore is an intellectual subject with its own substantial, worldwide body of scholarship. Part of the confusion lies in the use of the word folklore to signify both the content and the study of traditional materials. Further misunderstanding results from the varying senses of folklore in different countries. In much of South America and in some European nations, folklore generally applies to public performances of song, dance, and festival, and in scholarly usage the term refers to the study of peasant culture. In the United States, the word folklore often conjures up an image of folksingers or old-timers spinning yarns of Paul Bunyan and Johnny Appleseed, who are largely contrived. The German term *Folklorismus* and the English term *fakelore* have been coined to distinguish between the genuine and the synthetic.

THREE APPROACHES TO FOLKLORE

Serious students of folklore by no means agree on the boundaries of their discipline but they tend to follow one of three prevailing perspectives.

Emphasis on narrator

Humanistic perspective. The humanistic folklorist sees the materials of folklore as "oral literature" and the folk as its artistic performers. He emphasizes the creative role of the narrator or bard, seeks information on his biography and personality, closely observes his interaction with the audience, and analyzes his total repertoire much as a literary critic assesses the achievement of the novelist, poet, or dramatist. Usually the older exponents of this approach have entered folklore from departments of modern language and literature or music or classics. A case in point is Albert Lord, professor of Slavic literature at Harvard University, whose folklore interests developed from a concern with the south Slavic oral epic, still sung by bards in Yugoslavia. Lord came to the conclusion that each epic singer constructed his narrative song by improvising around a stock of fixed images, epithets, and conventional expressions, which he alone kept firmly in mind. This "oral-formulaic" theory Lord then applied to the Homeric epics, which are now known only in their written forms but which he conjectured had been orally composed in the same manner as the contemporary Slavic epic songs. The interest in the human carrier of tradition, in his worldview and belief system, his cultural inheritance and acculturative experiences, distinguishes this species of folklorist.

Emphasis on cultural norms and values

Anthropological perspective. The anthropological folklorist examines the materials of folklore using the hypotheses of the social sciences. He looks for cultural norms and values and predictable laws of behaviour that form a consistent pattern in the nonliterate society he has closely observed. Folklore to him is an aesthetic product of this society, mirroring its values and offering a projective screen that illuminates its fantasies. Hence the folkloristic anthropologist frequently reports a one-to-one correlation between the value system and the tale repertoire of a given culture, whereas the humanistic folklorist promptly points out that the same tales are found in many parts of the globe and so can scarcely be said to reflect the ethos of a particular people, even when they have been strongly localized.

-At different periods folklore and anthropology have enjoyed an intimate relation in England and America. The father of anthropology in England, E.B. Tylor (1832–1917), drew heavily upon the materials of folklore in his two great works, *Primitive Culture* (1871) and *Researches into the Early History of Mankind* (1865), which in turn contributed to the growth of a school of so-called anthropological folklorists. The leader of this school, Andrew Lang (1844–1912), a versatile man of letters, in many clever essays and books elaborated a theory of "survivals" based on Tylor's hypothesis that from the beliefs and customs held by peasants and contemporary savages the folklorist could reconstruct the ideas of prehistoric man. In the United States, Franz Boas (1858–1942), the father of American anthropology, influenced many doctoral students, later eminent in their own right, to pay attention to folklore in their fieldwork. Boas himself considered that tribal traditions preserved an ethnological record of older culture traits and should be consulted in lieu of written documents. His disciple and successor as editor of the *Journal of American Folklore,* Ruth Benedict (1887–1948), pointed out that the tribal mythology depicted violations of taboos, such as the hero-trickster sleeping with his mother-in-law, which would never be tolerated in real life. Another student of Boas, Melville J. Herskovits (1895–1963), broke with the Boasian concentration on North American tribes to explore African cultures but retained the same emphasis on folklore and inculcated this emphasis in his own students.

American folklore-minded anthropologists all experienced difficulty in employing the term folklore within a culture almost wholly oral and traditional and resorted to various substitutes. William Bascom, a student of Herskovits, suggested the term verbal art to denote the oral aesthetic traditions of tale, proverb, song, and riddle in the culture, leaving out the supernatural-belief system and the plastic arts, which a humanistic folklorist includes in his concept. Bascom also clarified the functional uses of folklore in nonliterate societies, in accord with the anthropologists' stress on the social mechanisms that enable a society to perform its business. His book, *Ifa Divination* (1969), demonstrates how Yoruba diviners have recourse to the tribal repertoire of traditional narratives in arriving at their analyses of individual problems. The beans they throw on the Ifa board fall in a series of complex patterns that the diviners key to folktales, whose contents are then applied to the particular situation in hand. English and American anthropologists of the 1960s have in the main moved away from the soft, folkloric parts of culture to the hard, sociological data of kinship organization and political structures.

Emphasis on behaviour

Psychological–psychoanalytic perspective. The psychological–psychoanalytic folklorist views the materials of folklore neither aesthetically nor functionally but behaviouristically. Myths, dreams, jokes, and fairy tales are taken to express hidden layers of unconscious wishes and fears. Sigmund Freud drew extensively upon folk sources in such works as *The Interpretation of Dreams* (1899), *Jokes and Their Relation to the Unconscious* (1905), and *Totem and Taboo* (1913). In his view, and that of many writers on folklore influenced by him, folklore texts are to be interpreted symbolically in terms of sexual imagery and the Oedipus complex. In "Jack and the Beanstalk," the stalk is construed as a phallic symbol and Jack's chopping it down signifies a masturbation fantasy. "Little Red Riding Hood" tells a tale of a young virgin, identified by the red cap, a menstrual symbol, who wanders from the straight and narrow path, to be devoured (seduced) by the wolf in disguise as the grandmother, an Oedipal figure. In the modern college legend "The Hook," the torment suffered by a coed is multilayered: she narrowly averts assault from an escaped lunatic, one of whose arms has been replaced with a metal hook; the psychological interpretation explains the hook as the phallus and the episode as the coed's fear of the sexual act. When C.G. Jung broke with his mentor Freud and substituted the symbolism of social unconsciousness for the symbolism of sexual drives, he still retained his deep interest in myths, dreams, and tales as psychoanalytic media, and the Jung Institute in Zürich continues to offer courses on the uses of folklore in psychology.

Such a work as *The Trickster,* edited by the American anthropologist Paul Radin, with commentaries by the mythologist Károly Kerényi and by Jung, offers within a single volume three psychoanalytical interpretations of the Winnebago cycle of trickster tales. Kerényi, although he was a collaborator of Jung, takes a Freudian position and sees the trickster as a phallic figure, the spirit of disorder. Jung finds unconsciousness as the chief and alarming characteristic of the trickster, whom he considers the forerunner of the Saviour. Radin synthesizes both Freudian and Jungian analyses in his conception of the trickster as evolving from a psychically unaware individual to a socially developed being, reinterpreted by each new generation as god, hero, or buffoon. The most committed Freudian folklorist of the 1960s was Gershon Legman, who was Hungarian by birth but resided in the United States and France. In *The Rationale of the Dirty Joke* (1968), Legman properly gives attention to the most current folktale genre of modern society but looks beneath the seemingly obvious motivations of dirty jokes to violate sexual and anal taboos and imputes to them such latent impulses as male castration fears, female revulsion at the sexual act, and homosexual drives.

The three perspectives of folklore are not mutually exclusive. Anthropologists may at times employ an essentially humanistic approach, as Daniel J. Crowley has done in his detailed ethnography of the styles and repertoires of Bahamian narrators, *I Could Talk Old-Story Good* (1966). They also have shown sympathy for the psychological–psychoanalytical node. A case in point is the study of *Water-Witching, U.S.A.* (1959), by anthropologist Evon Vogt in collaboration with the psychologist Ray Hyman, who explained the widespread phenomenon whereby diviners, called dowsers, located underground water with a forked branch as an anxiety-releasing mechanism for depressed farmers. Younger folklorists of the 1960s trained as humanists have shown an increasing orientation toward social-science methods of model building and statistical techniques.

THE ORIGINS OF FOLKLORE

Grimms' Fairy Tales and the collection of folklore

When scholars and other intellectuals began to recognize early in the 19th century the presence in their midst of a vast floating body of folk traditions and practices, they promptly began to speculate on its origins. When in 1812–14 the German philologist Jacob Grimm (1785–1863), together with his brother Wilhelm (1786–1859), published the first volume of the *Kinder und Hausmärchen* (customarily translated as *Grimms' Fairy Tales*), thus initiating the science of folklore, he connected his collecting of village tales to an elaborate mythological system of origins, outlined in his *Deutsche Mythologie.* This influential work was first issued in 1835, and its fourth edition was translated into English (3 volumes, 1883–88) under the title *Teutonic Mythology.* A German nationalist, Grimm postulated a highly developed religious pantheon of pre-Roman times suppressed by the medieval church and surviving only in broken fragments of peasant beliefs and stories. The *Märchen,* or tales, were the detritus of the old myths.

In the mid-19th century, following the discovery of Sanskrit as the ancient classical language of India and the

"Disease of language" theory

parent of European tongues, a pan-Aryan theory of origins developed. In 1856 Max Müller, a German-born scholar who went to London to translate from the Sanskrit the *Sacred Books of the East* and stayed on at Oxford University, published a long essay on "Comparative Mythology," introducing the new theory. Through a process he called "disease of language," Müller conjectured that myths arose from forgetfulness of the original names of deities, transferring to them metaphorical qualities suggested by the names. Thus Dyâus, the sky deity of old India, would be thought of and narrated about as the sky, or by association, heavens, clouds, storms, and winds. The Greek myths sprang from the Indic—Zeus was the linguistic counterpart of Dyâus—and could be explained on the same grounds. Although Müller applied his theory only to the advanced Indo-European Aryan civilizations, he did point to similar myth-making among primitive peoples. Some of his followers, notably George W. Cox, carried the school of solar mythology to extreme limits and explained all folk narratives, epics, and ballads as originating in early man's poetic rendering of the conflict between the sun and the night.

Tylor added a new conception of the origins of folklore without challenging Müller's solar mythology but by pushing the starting point back beyond the Aryans to prehistoric man. Looking at the universe animistically, primitive man endowed the elements, the animals, the plants, and the rocks with personalities and souls. Such beliefs survived into modern civilization among the unlettered lower classes and formed a crust of folklore. The strongest challenge to Tylor's evolutionary theory of culture and "devolutionary" theory of folklore (in the phrase of Alan Dundes) first emerged in a hypothesis advanced by the German scholar Theodor Benfey in his introduction to the Indian story collection *Panchatantra* (1859). Benfey claimed that India, the seat of an ancient high civilization that had spread to Europe, was the home of the master tales subsequently found in the Grimms' collection. Along with language and mythology, these wonder tales had diffused from India to Europe in ancient times and again in historic times along well-traveled trade routes. Benfey's arguments persuaded other folklorists, notably Emmanuel Cosquin in France and William Alexander Clouston in Scotland, who added to his evidence of story migration from India eastward. In the past century, the primacy of ancient India as the fountain of world folklore has gradually been whittled away by the claims of other dispersal points, such as Egypt and Greece, and by the growing realization that no sweeping generalization could account for folklore origins. According to the Finnish folklorists, whose historical-geographical method attracted most scholars in the first half of the 20th century, the life history of each complex tale and ballad requires separate investigation. After exhaustively comparing the traits of all the assembled variants of a given tale type, the Finns (specifically Kaarle and Julius Krohn and Antti Aarne) believed they could establish its original form and approximate place and period of genesis. The subscribers to this theory accepted the premise that an anonymous composer had created every substantial folklore item at one point in time, much as a novelist produces a novel.

Folklore and fertility ritual

Various other origin theories have gained attention. The school of Cambridge University anthropologists, theorizing on the great comparative study by Sir James George Frazer, *The Golden Bough* (1st ed., 1890), converged on a central idea of myth-ritual origins of all folklore. In their view, a mythic narrative accompanied and explained a sacrificial fertility ritual among the heathens. In the course of time the myth becomes separated from the rite and floats independently in oral tradition, to splinter in turn into magic tales, popular ballads, nursery rhymes, and other folklore genres. Psychological folklorists ascribe the source of many folk narratives to dreams; the Hungarian Geza Roheim considers that dreams, precipitated by full bladders, engendered the widespread flood myth. Ballad scholars, such as Francis Gummere in *Old English Ballads* (1894) and other works, attributed the composition of ballads not to any single bard but to the joint efforts of a singing, dancing throng.

Origins by social classes have also formed the basis for widely held theories. One thesis, particularly identified with the German Hans Naumann and his term *gesunkenes Kulturgut* (literally, "downsinking cultural value"), contends that folklore originates with the aristocratic upper class, whose court poetry, mimes, bardic recitals, and pageants filter down in debased form to the peasantry. Russian and east European folklorists have sharply challenged this idea since the 1930s and substituted their own concept that folklore arises from the people, the folk, in expression of protest and outrage against the exploiting nobles and landowners. Hence in Russia folk bards and storytellers are honoured along with novelists and poets. In "A Theory for American Folklore" (1959), Richard M. Dorson has argued for a distinction between Old World and New World folklore origins. The folk traditions of North and South America combine the imported lore of the conquerors, the aboriginal lore of Indian tribes, and the lore arising since the colonizing period as a result of New World history and geography.

THE FORMS OF FOLKLORE

The elusive materials of folklore are best defined through the formal genres into which they fall. Genre definition has its own pitfalls, since attempts at neat categories invariably slice off related forms; however, folklorists do agree on certain broad kinds of traditions. These may be divided into oral literature, custom and festival, and material culture.

Genres of oral literature

Oral literature. The genres of oral literature cover spoken and sung expression. They may be further divided into the two large groupings of folk narrative and folk song, and such other smaller genres as proverbs, riddles, and beliefs or superstitions. *Folk narrative* is an umbrella for a wide range of oral prose traditions. Among them can be mentioned the *myth*, a semisacred adventure of a god or demigod set in the remote past; the *Märchen* or *fairy tale* (also *wonder tale* or *magic tale* and sometimes just *folktale* or *tale*), a pan-European popular fiction with aristocratic characters, magical episodes, and a symmetrical structure; the *legend*, a believed report often told conversationally and allusively; the *saga*, a personal, family, or local chronicle of marvellous oral history; the *romance*, a lengthy, adventure-filled narration with realistic characters; the *noodle* or *numskull tale*, relating the comical stupidities of a foolish person or a village of fools; the *jest* or *joke*, a short humorous fiction, often obscene and usually climaxed with a punch line; the *anecdote*, a brief traditional incident concerning a laughable action or saying of a historical personality; the *animal tale*, characterized by talking animals with human traits; the *cantefable*, a story containing songs or rhymes; and still other forms. Folk song, too, embraces myriad species. An important aspect of all folk songs is their association of text with tune, requiring the folklorist to trace the melodic as well as the textual history. A major division separates the *ballad*, which embodies a narrative, and the *lyric*, which expresses emotion, although, like *Märchen* and legend, the two basic forms often coalesce. The ballad can be further subdivided into the *Child ballad*, named for Francis James Child, who assembled 305 basic types of the English and Scottish traditional ballad (1882–98); the *broadside ballad*, a later development of the 16th and 17th centuries when balladmongers wrote up sensational events on broadsheets or broadsides and hawked them in the streets; and *European* and *American ballads*, which have evolved from local events. Other folk song genres range from the Russian *bylina*, or epic songs of a medieval hero, to the *lullaby*, used to sing a child to sleep.

Still another category of oral literature comprises *folk speech*, as distinct from formal or standard speech, and various traditional kinds of expressive utterances. Prominent among them are the *proverb* or folk saying, embodying wisdom in pithy phrases; the *riddle*, an enigmatic question paired with a deceptive answer; the *tongue twister*, a nonsense sentence difficult to pronounce because of its string of assonances; the *toast*, a convivial expression voiced as a drinking salutation; along with other forms involving a special use of language. *Beliefs* or *superstitions* are sometimes expressed as wise sayings, although they may also appear in tales and in customs.

Material culture. At the opposite pole from oral literature in the spectrum of folklore lies material culture or folk life, terms used to denote the physical objects produced in traditional ways. Material culture thus embraces folk architecture, folk arts, and folk crafts. Under these headings can be placed the construction of houses, the design and decoration of buildings and utensils, and the performance of home industries, according to traditional styles and methods. The shape of fences, the making of sorghum molasses, and the sewing of quilts all fall under material culture.

Custom and festival. Between oral and physical folklore there is a large middle ground filled by custom, ritual, festival, children's games (believed to be versions of adult rituals), folk drama, play parties, rites of passage, folk dances, and equivalent genres involving action, performance, and paraphernalia. To the verbal and tangible elements are added group behavioral traits.

The functions of these three genres vary for individuals and societies, but generally it may be said that material culture fills economic and aesthetic functions, that oral literature fills didactic, recreational, and educational functions, and that custom and festival function to provide psychic reassurance against external dangers. Rites placate gods and demons, tales and songs entertain and instruct, and home-baked bread on a hand-carved table fills the stomach while pleasing the eye.

THE GENERAL FUNCTIONS OF FOLKLORE

The escapist function

A behavioral classification of functions. Oral literature, like written literature but even more pronouncedly, satisfies the desires of mortals to transcend their mundane world. In the myths the heroes visit the otherworld; in the legends ordinary folk are taken to fairyland; and in the *Märchen* the youngest son or daughter of a peasant family makes a royal marriage. Gold, treasure, and wealth are prominent in narrative folklore. Jason and the Argonauts in Greek myth set out for the Golden Fleece; in fairy tales a magic goose lays golden eggs; and in real life, treasure seekers dig for the buried booty of pirates and outlaws. The Irish tradition of "Seán Palmer's Voyage to America with the Fairies" (in *Folktales of Ireland* by Sean O'Sullivan), told as an actual experience befalling Seán Palmer of County Kerry, combines the traditional theme of fairies transporting mortals to distant cities with a wish fulfillment fantasy. Seán believes the fairies take him by boat overnight to the United States, where he visits relatives in New York and Boston and is given money, new clothes, and tobacco. Many Irishmen have relatives in the U.S. whom they consider rich and long to visit.

Another way in which folklore lifts man above his narrow confines is in the breaking of powerful social taboos. What man can never do in actuality without incurring severe punishment the trickster in black American narratives, for example, does with impunity, such as John the slave slapping the face of his white mistress. Modern jokes with their heavy emphasis on genital-anal humour similarly arouse merriment by flouting taboos.

The etiological function

Mythic narratives and explanatory episodes in other kinds of folktales answer man's perennial questions: How did the world begin? Who created man, the animals, and the plants? The book of Genesis in the Bible gives two versions of a creation myth with worldwide analogies. Myths of origin are always ethnocentric; they explain the creation, by supernatural powers, of the people possessing the myth, a chosen people. The hostile, formidable, mysterious universe assumes a familiar outline through the personification of a creator and his adversary and of associated deities and demons with their own spheres of influence. Tribal peoples need their myths to safeguard their identity. An Ojibwa Indian in northern Michigan asked a researcher on their first meeting, "Do they have thunderstorms in South America?" On receiving an affirmative answer the Ojibwa turned morose and taciturn and refused to speak further. He had wished reassurance that thunderstorms existed only in the neighbourhood of Lake Michigan, since the Ojibwa protective deities were thunder spirits. Later, when mollified, he related a version of the creation myth, synthesized with the flood myth. The culture hero-trickster figure, Winabijou, flees from the underneath serpents, who send flood waters after him. He takes refuge atop a pine tree and barely keeps his head above the water that covers the earth. Water animals swim to him, and he sends them down to the bottom; the muskrat comes up with mud in its paws, with which Winabijou makes a little island. Each day the island gets bigger, and Winabijou sends the fox along the shore to circle it and report back. Eventually the island grows to the size of the present earth. "And you can see a fox trotting along the shore today," the narrator concluded. "The shore gets bigger too. Sand multiplies. When I first came here the beach on the cove was only half as big as it is now." The myth satisfactorily accounts for his universe.

The justifying function

Just as myths are generated to explain the physical world and its inhabitants, so does folklore at large provide support for the institutions and behaviour patterns of a culture. In nonliterate societies the central events of human life—birth, attainment of manhood, marriage, and death—are invested with elaborate ceremonials by which the social organism marks the mortal's progress and final exit to the afterlife. In modern society the quasi-religious character of these passage rites, as Arnold van Gennep has termed them, can be observed in the rituals of baptism, confirmation or graduation, weddings, and funerals, which are sometimes secular, sometimes ecclesiastical, and sometimes a mixture of both. In contrast to supernatural beings, who acquire anthropomorphic personalities and walk the earth (like Winabijou, or Christ and St. Peter), historical heroes acquire supernatural attributes and move heavenward. The illustrious secular heroes and heroines—like Joan of Arc, Confucius, Peter the Great, Julius Caesar, King Alfred, and George Washington—become national symbols, consecrated with monuments, holidays, hagiographic literature, and folk legends. They function in the national culture as standard-bearers of the values and goals of the nation. The legend of young George Washington saying to his father, "I cannot tell a lie, it was I who chopped down the cherry tree," drives home the moral of the proverb ascribed to Benjamin Franklin (but actually common in Europe in the 17th century and earlier), another culture hero: "Honesty is the best policy."

The pedagogic function

A good deal of folklore, especially the proverbs, fables, cautionary tales, and confessional ballads, serves to instruct and remind members of society of wise codes of conduct. The proverb and the fable may teach the same lesson; "Pride goes before a fall" is illustrated in Aesop's fable of the cat who praised the crow's singing voice, so that the crow up in the tree started to sing and dropped the cheese from her mouth to the ground. Proverbs may sometimes appear contradictory. "Look before you leap" is challenged by "He who hesitates is lost," but each saying contains its truth to be applied to a given situation. A whole ethic may be summarized in a proverb, as is the Protestant ethic of hard work in the saying, "Early to bed, early to rise, makes a man healthy, wealthy, and wise."

Although proverbial expressions are still frequently uttered in industrialized societies, they are used as mild commentary and poetic cliché rather than, as in African societies, for firm codes with the force of judicial precedent. The African novelist Chinua Achebe writes in *Things Fall Apart,* "Among the Ibo the art of conversation is regarded very highly, and proverbs are the palm-oil with which words are eaten." And his novels are sprinkled with proverbs. Actual court cases among the Anang Ibibio of Nigeria in which judges were swayed by proverbs have been recorded by the anthropologist John Messenger. On one occasion the chief judge advised the plaintiff and his witnesses, "If you visit the home of the toads, stoop," when they refused to make their statements under oath and thereby forfeited their case. The equivalent precept, still forceful in modern life, is "When in Rome do as the Romans do." Among the Bambara-speaking people of Mali in Africa, the *griots,* the celebrated epic bards, customarily "warm up" before their recitations and during breaks in their lengthy performances by singing proverbs in rapid sequence. This practice serves the function of gaining the attention and respect of the audience, who think of proverb sayers as wise men knowing how the society works; hence the listeners will be ready to credit the historical tradition that follows.

The controlling function

Besides suggesting rules for conduct, folklore also drives home the need for proper social behaviour by holding up to scorn those who depart from socially accepted norms and by eulogizing those who follow them. Jokes, the most popular form of oral literature in modern society, ridicule stereotyped characters who display traits disparaged by the Establishment. The stingy Scotsman, the miserly Jew, the ignorant Irishman, and the stupid Polack are all caricatured in joke cycles whose implicit values laud the qualities of liberality, generosity, intelligence, and cleanliness. Anecdotes of local characters similarly excoriate the slovenly, shiftless, degenerate, gullible, and naïve. One favourite theme of anecdotes is the lazy man, often identified with some local ne'er-do-well. Starving to death, the lazy man is offered popcorn: "Is it shelled?" he asks, and prefers to starve rather than do the labour of the shelling. Just as proverbs teach the gospel of work, so do such anecdotal legends mock the idle and improvident. Conversely, folklore also exalts individuals who exemplify the virtues considered admirable in the culture. Saints' legends recount the miraculous cures and rescues that the saint revered by the folk (who is not necessarily canonized by the church) has effected for the faithful. Devout members of the Mormon Church continue to relate experiences of succour given them in distress by one of the three Nephites, who appears as a stranger in white garments to render assistance and vanishes as mysteriously as he materializes. Heroes in ballad, legend, and *Märchen* reflect the dominant values of their societies and are rewarded by success. The champion of heroic epics is an invincible warrior. The hero of Negro ballads is a big-talking badman. The modern hero in the anecdotal legends of youthful dissenters is the antihero who sells LSD pills or marijuana and outwits narcotic agents, the police, and draft boards. All these heroes symbolize ideal types for their social groups. Deviation from the ideal brands the nonconformist a coward, an Uncle Tom, or an Establishment toady. In the form of folklore known to 17th-century American Puritans as the "remarkable providence," God punished sinners, blasphemers, heretics, witches, marauding Indians, and critics of the state with acts of supernatural vengeance, while rewarding his elect with supernatural assistance during their wilderness trials. Puritan clergy collected and published these providences as lessons and guideposts for their people. In Socialist countries of the 20th century, the governments have taken a hand in the process of regulating conformity by awarding prizes to folk poets and folk narrators who attack bourgeois and capitalist villains and extol peasant and Socialist heroes.

A cultural-geographical classification of functions. Generalizations about the functions of folklore need to be qualified by considerations of culture area and social milieu. One kind of distinction should be made between Old World and New World folk traditions, since North and South America were colonized by Europeans, who then transported African slaves to their overseas empires. Consequently, a given country of the New World possesses several coexisting and interacting traditions; the indigenous Indian; the colonizing Spanish, Portuguese, French, or English; the African Negro; the 19th- and 20th-century European and Asian immigrant; and the national and regional, shaped by new historical and environmental factors. The continent of Australia also belongs with the New World in this regard, its folklore being divided between the Aborigines and the English settlers. In the colonized nations, each folk tradition serves to reinforce the group identity of its members in a pluralistic culture. Syncretism, or the fusion of different traditions, is a process especially characteristic of New World folklore. The miraculous appearance of the Virgin of Guadalupe to the Aztec Indian Juan Diego in 1531, who received from her a painting of herself on his cape, brought together Spanish-Catholic and pre-Conquest Indian strains. Mexican Indians and mestizos identified the Virgin with an Aztec goddess Tonantzin, pictured her as dark in hue, and celebrated her with costumed dances of pagan origin but within the framework of Roman Catholic worship and beatification. The ballad of "John Henry," relating the contest between a brawny Negro labourer and a new steam drill on a railroad tunnel in West Virginia in the 1860s, is widely sung by both American blacks and whites. John Henry dies "with his hammer in his hand," and interpreters see him as a symbol of the unequal struggle of the black man against the white, and of man against the machine. Immigration has brought large numbers of Slavs to western Canada, Japanese to Brazil, Italians to Argentina, Germans to Chile, and many peoples to the United States, whose folkways partially survive the transoceanic crossing. The traditional lore physically connected with the original homeland seems to vanish the most quickly; thus the Irish belief in fairies does not survive, since the grassy circular "fairy rings" inhabited by the fairies of the Old Country are not found in America.

Literate and nonliterate functions

Another large distinction in the functioning of folklore separates the so-called nonliterate societies lacking written languages from the advanced civilizations engulfed in print. Reliance on the oral tradition is obviously far greater in the nonliterate cultures. The matter of recording history provides one example: instead of referring to printed books containing a great many facts that no one person could or would wish to keep in his head, the tribal groups depend upon reciters of historical traditions, some of whom, like the *whare wananga* of the New Zealand Maori, the sagamen of 11th-century Iceland, and the *griots* of Mali, have a professional status. These annals and genealogies bear little resemblance to documented written histories and belong properly to the products of oral literature, since they include magical and marvellous episodes of folktales and legends. They do correspond in function to national histories in celebrating the achievements and culture heroes of a chosen people. An ingenious study by two teams of American anthropologists who collected traditions from two rival Indian tribes in northern California revealed a similar patterning but contrasting roles for the same characters and events. The enemy tribe was always guilty of the provocative incident, fought dishonourably, and suffered defeat.

Even in literate civilizations large enclaves of largely oral, tradition-directed cultures persist. Narrators with enormous repertoires have been located in the 20th century in the Gaelic-speaking highlands and islands of western Scotland and western Ireland. Peig Sayers of the Great Blasket Island related 375 tales to the collectors of the Irish Folklore Commission, many of them long wonder tales taking all evening or several evenings to complete. In modern urban, technological society, such reciters find no audiences. Life has too many distractions and diversions and sources of information. Nevertheless, story-telling continues among the highly literate, in the form of joke-telling sessions, which may last an hour or two; but the jocular narratives are relatively brief, snappy, and quickly climactic. They serve as icebreakers to establish camaraderie in a group, although they may also give offense to some members of a social gathering with differing political or moral views. Ballad making originally made possible the dissemination of sensational news in attractive form and receded with the advent of newspapers, which emulated many of the same techniques of ballad makers in their handling of lurid news items.

Correspondence between oral and literary cultures

Oral and literary cultures are no longer sharply divided. On the lower levels of society cheap printed sources—such as chapbooks, broadsides, jestbooks, mass magazines, almanacs, and newspapers—feed materials into and draw from oral streams of lore. In the electronic age, according to Marshall McLuhan, the literate world is reverting to an oral-aural community.

Folklorists at first identified their subject with the rural peasantry. Seasonal festivals, old wives' remedies, supernatural beliefs in demonic figures, and magic makers flourished in the countryside. Cities were the centres of learning, industry, and wealth, and the spoilers of tradition and folklife. This easy contrast is being revised as folklore scholars turn their attention to the cities where ethnic neighbourhoods and occupational workers form closely knit, tradition-bound societies. A team project of Hungarian folklorists investigating Budapest reported many vigorous manifestations of traditional behaviour, such as May Day celebrations, dancing parties held by tradesmen, housewarming ceremonies, and occupational jokes. In a detailed study of a Tokyo district, R.P. Dore reported on households that maintain traditional festival practices and the ancient Shintō beliefs in *kami* (deities) and *fuda* (shrine amulets). But city life does of course affect traditional ways brought in from the country. The ubiquitous Japanese-peasant conception of the *Kappa*, a dangerous boy-goblin with an inverted saucer on his head containing magical water, is found in Tokyo in newspaper comic strips, on decorative designs, or as a character in a novel by Akutagawa Ryūnosuke. In a series of ethnographic studies in Yucatán, the American anthropologist Robert Redfield compared four communities, ranging from the simple village to the complex town, and found that living rituals in the village become desiccated superstitions in the town.

Field research in the steel-manufacturing cities of Gary and East Chicago, Indiana, by Indiana University folklorists has shown not only a decrease in the folklore genres of the many ethnic groups living there but also an emergence of a new city lore. The chief elements of this lore derive from the human side of the all-encompassing steel industry, from fears and rumours about crime, and from anecdotes and stereotypes about other racial and ethnic groups. This emerging lore provides a sense of solidarity and rootedness in the impersonal, unlovely city.

THE DIFFUSION AND ACCULTURATION OF FOLKLORE

Folklore is at once remarkably stable and remarkably shifting. These phenomena have intrigued folklorists, who explain the apparent paradox through the mechanism of diffusion. A complex item of folk tradition, whether an epic song, a house style, a folk drama, or a wonder tale, once it has attained coherent form, may travel across continents and oceans and endure through the centuries. The basic type retains its outline but external features are continuously modified and adapted to new surroundings. Barriers of language, religion, and culture offer no obstacles to the movements of folk products. The most bitter of enemies share the same traditions. Supporters of diffusion challenged the upholders of independent invention in the latter decades of the 19th century and eventually won the day as depth field studies proved clearly the wanderings and migrations of individual texts. The first comparative study of a folktale, Marian Cox's *Cinderella* (1893), brought together 345 variants of the same recognizable story plot. Even legends, seemingly so anchored in time and place to specific historical events and personalities, were shown to migrate and become attached to different localities and heroes. The legend of the Returning Hero, sleeping in the fastnesses of the mountain with his warriors until his people would summon him to their rescue, fastened on to Frederick Barbarossa, King Arthur, and Thomas the Rhymer and is still told of modern figures. How did folklore diffuse? Proponents of diffusion offered various explanations: sailors, merchants, and travellers transported folk matter along the great historic trade routes; Gypsies acted as peddlers of folklore; borders between peoples served as bilingual zones through which songs, tales, and styles easily moved; imperial powers planted the traditions of the mother country in distant places. All these hypotheses have some merit; European tales found among North American Indians, for instance, undoubtedly date back to the period of their first culture contact with French and Spanish missionaries, soldiers, and traders. Yet Indian tales did not lodge in the narrative repertoires of the European settlers. The flow appears to go from literate to nonliterate cultures.

Acculturation represents a somewhat different phenomenon of folklore movement. Here not the lore but the folk move, bearing with them their ancestral heritage. What happens to this heritage when peasants of India resettle in Africa, when Chinese move to Malaysia, when European communities pour into the New World? The resulting process of adjustment, adaptation, compromise, and assimilation is called acculturation. But what takes place in this process is not so easily understood. Parts of the Old Country tradition recede into "memory culture," to be recalled on direct stimuli but otherwise lying dormant in the recollections of the first generation. Other parts remain in vigorous use. Still other parts take on New World coloration. Among Greek immigrants in the United States, for instance, the telling of paramythia (or *Märchen*) and the sighting of creatures like the *vrykólakas*, a vampire demon, have virtually ended, but the belief in the power of the evil eye and of the protective power of saints remains as strong as ever. As a general principle, the beings of lower mythology do not transplant into an alien environment, whereas the daily and seasonal rituals and associated beliefs can be maintained within compactly settled groups. The rate of acculturation will vary greatly between immigrant societies, depending upon what conservative forces are at work. Such groups as the Pennsylvania German Amish and the Hasidim in Brooklyn, N.Y., retain a high degree of their magical belief system, folk arts, and ritual observances, because they have made strenuous efforts to wall themselves in from the mainstream of American culture, an effort strengthened by their independent churches. By contrast, Irish-Americans after a century in their new homeland have lost most of their distinctive folklore and blended in with the rest of the general Catholic and middle class population.

The mobility and technology of modern man have noticeably affected the diffusion and acculturation of folklore. People emigrate by airplane, communicate by telephone, and soak information from the mass media. Yet old ways of thinking and believing show remarkable tenacity. Many folk today discredit the landing of men on the moon as a publicity hoax contrived by the United States government and the television networks. These are the people who have seen flying saucers, been cured by faith healers, and conversed with revenants. Folklore is as old, and as young, as man. (R.M.D./Ed.)

Folk art: general considerations

19th-century notions of folk art

Under the influences of 19th-century sentiments, the concept of "folk" was affected by a fondness for the picturesque, by generous impulses toward aesthetic democracy, by the so-called arts and crafts movement, by historicism and philosophical Idealism, by nationalism and regionalism, and by an occasionally aggressive, wildly mystical sort of ethnocentrism. Thus, folk art was defined, if only by the implications of usage, sometimes as almost anything that could be considered quaint; sometimes as all non-elite art, primitive and popular included; sometimes as whatever seemed vaguely homemade; sometimes as the art of the common people, but with the latter regarded as a ghostly entity existing outside of real class structures; and sometimes as a traditional, characteristic art that preserved a cultural heritage and somehow represented the collective soul of a nation or a province. There are some more or less acceptable elements in such definitions. What is missing is a flat enough acknowledgment that folk art is the recognizable product of a nonruling, relatively unaffluent social class and that references to it except in relation to the elite art of a ruling class are meaningless.

A core description of folk art

Putting all these considerations together, one arrives at what can serve as a core description. Unmistakable folk art is the art of a class of peasants, herdsmen, seamen, artisans, and small tradesmen living as a rule away from urban centres in societies that, while literate and highly civilized, are not highly industrialized. Such societies were to be found in Europe, particularly eastern Europe, until well into the 20th century, and they will still exist, of course, on other continents. Where they no longer exist, the term folk may still be appropriate for the art of social or ethnic minorities that have preserved earlier traits by living apart, culturally and often physically. More doubtfully, the term may be extended to certain traditional artistic productions—especially those associated with carnivals, national holidays, religious processions, and the like—that are the work of thoroughly unfolkish city people.

FUNDAMENTAL CHARACTERISTICS OF FOLK ART AND THE FOLK ARTIST

Although the folk kind of art is invariably produced, according to the only definition that makes serviceable sense, in a culture that also produces the elite kind for a ruling class, the usual elite classification of the arts into the fine, or independent, and the useful, or decorative or dependent, is pretty much ignored by folk visual artists, who are typically willing to devote their creative imaginations to the design or decoration of tools, toys, furniture, cottages, clothes, arms, banners, musical instruments, and so on. The portrait of a Spanish patron saint may appear in embroidery; narrative pictures belonging, according to the European academic classification, to the elevated "history" category are painted on Sicilian carts. Something of the same mixture of the so-called high and low is typical of folk literature, music, and dancing: tragedy takes ballad form and a noble war dance the form of a Highland fling.

Artists and patrons. In some ways the usual folk artist can be called an amateur. He lacks professional training, he normally has a second, more remunerative occupation, and he creates primarily for his own pleasure and needs or at most for those of acquaintances in his own small locality. But in other ways he is quite unlike an amateur artist in a nonfolkish social context. He is apt to work strictly within the limits of a traditional formula, he often remains anonymous, and often he is an artisan who carries over into his works of art his everyday skill. Amateur is not quite the word for a blacksmith who designs a fantastic shop sign in wrought iron nor for a baker who turns out figurines.

Materials and techniques. Works of visual folk art are rarely executed in anything except readily available, fairly inexpensive materials. A sculptor is likely to work not in marble or bronze but, rather, in wood, iron, clay, straw, ice, sugar, or whatever else is at hand; a painter may substitute an old board for the elite artist's canvas or special paper. Perhaps because of this situation and perhaps because of the already mentioned tendency to ignore the separateness of fine art, the folkish creator displays little of the elite (or, for different reasons, the primitive) concern to employ a specific technique for a specific material—to respect what a French art historian has called the vocation of each sort of artistic material. Folk wooden sculpture may be carved in a manner suitable for granite; painting may be done in an approximation of embroidery technique; pottery may bear incised patterns borrowed from metalwork or basketry; and almost any material is apt to be disguised under bright colours.

Styles. Encouraged by local patriotism, scholars have divided folk art into mostly national and regional styles: English, French, German, or Spanish folk music, Breton, Provençal, or Balkan costumes, Pennsylvania Dutch decorations, Mexican processional figures, and so on. This sort of classification is justified by the remarkable traditional and settled nature of much of folk art. But it should not be allowed to obscure, as it frequently does, the existence of other sorts of style, nor should it suggest that these national and regional manners are without histories. There are Jewish, Christian, Islāmic, and other religious folk styles; mountain, valley, and seaboard styles; classical, romantic, realistic, fantastic, and expressionistic styles; and naturalistic and abstract styles. There are period styles; in fact, a sizable number of vaguely ahistorical-looking provincial folk styles are arrested styles of the 18th and early 19th centuries.

MEANINGS AND FUNCTIONS OF THE FOLK ARTS

Conservative and preservative qualities in folk art

Although the folk, defined as a class, live in nonprimitive societies, they are more or less isolated from the urban centres in which cultural change may be relatively rapid; and in their predominantly rural environments they are close to nature and to the basic birth-to-death cycle of human existence. Hence folk art is strongly conservative and preservative; in fact, it is often referred to as simply traditional art (with the unfortunate implication that other kinds of art do not possess traditions). It acts as a repository for proverbial wisdom, ancient superstitions, sentimental themes, and religious beliefs that may have long since ceased to be orthodox; it accompanies and celebrates what is repetitive in the lives of individuals and of communities—baptisms, marriages, funerals, anniversaries, sowings, reapings, and the daily routine of work. Often it preserves customs the meanings of which have been largely forgotten; the colouring of Easter eggs and the decorating of Christmas trees are familiar examples. Often, too, the old meanings are given an unexpected twist by a naïve or eccentric artist. But, on the whole, folk art functions within its sphere, as does primitive art in an entire society, on the side of continuity and social stability; and there is some justification for 19th-century talk about the expression of a collective "soul."

The "soul," however, is not so much that of a nation, a race, or a province as that of a social and economic class. The best folk art reflects the common sense, unpretentiousness, humour, and peculiar slyness of humble people in contact with small, hard realities; and not infrequently it reflects hostility toward the rich and powerful. In folk depictions of the Nativity, a gift bearer may bring not frankincense and myrrh but, instead, a jacket for the baby Jesus; in a harvest song, one may suddenly be informed that "the gentlemen," not the corn, are about to be mowed.

THEORETICAL ISSUES

Diffusionism, environmentalism, and related theories have aroused polemicists in the field of folk art as well as those in primitive art. But perhaps stronger feelings can be, or have been, stirred among folk-art specialists by theories that attempt to answer the two rather loaded questions of how folk art is created and, second, what the difference is between a folk art and a folkcraft.

Theories about the creation of folk art

The first question has some of its roots in the facts that the adjective folk may connote "communal" and that folk art is often the work of unknown creators. Other, probably more important, roots lie in the fact that, by the beginning of the 19th century, German Romantic thinkers were committed to myths (at that time fairly harmless) about the collective spirit, or virtue, of a nation or a race. The result was the idea, set forth with varying degrees of explicitness, that folk art—in particular, poems, melodies, and dances—was a communal creation. This idea was eventually replaced by a theory of communal re-creation or communal growth in situations in which the work of an individual poet, singer, or dancer is preserved only in memories and is modified as it passes from locality to locality and from generation to generation. In the meantime another largely German idea, that of cultural sinking, was provoking argument. According to this idea, folk art—visual art in particular—is derived, after a lapse of several decades or even several centuries, from the elite art of a ruling class; thus a Crucifixion carved by a 19th-century Breton peasant is explained as a late-provincial imitation of the 17th-century Baroque of Paris and Versailles. On all these matters the opinion of a majority of modern scholars is apt to be conciliatory. Although collective improvisation is not impossible, the original creator of a work of folk art is practically always a single artist. But it is possible to grant that a good deal of communal re-creation occurs in literature, music, and the dance and that in the folk visual arts the role of the individual creator, subject as he is to the demands of tradition and function, is not as decisive as it is in elite art. Again, it can be granted that folk art is often a belated borrowing from elite. But this need not prevent recognition of the fact that the folk as a class have their own traditional themes and forms.

Difference between a folk art and a folkcraft

The question about the difference between a folk art and a folkcraft is partly philosophical (which is not a reason for neglecting it) and partly quite practical, at least for museum curators who must classify exhibits, for specialists interested in a proper division of labour, and for modern educators or animators who want to continue the 19th-century arts and crafts movement. It has been argued that, where an artist creates, a craftsman merely fabricates; that, whereas the first is a nonmaterialist who makes something for the sake of expression or of disinterested contemplation, the second is a materialist who makes something for a definite function; and that, whereas the first cannot know exactly what he is going to produce, the second has an extremely precise foreknowledge accompanied by a plan and a method of execution. On this argument many alleged works of folk art can be dismissed as works of mere craft. But the argument is challengeable, partly on the familiar ground that art is in the eye of the beholder.

Although folk art, as was pointed out above, may borrow from elite and although it may also lend motifs to everybody from classical musicians to modern dress designers, it has proved incapable of surviving in the world of 20th-century industry and communications. Like primitive art, it can live only in isolation. Unlike primitive, however, it has demonstrated, particularly in the performing arts, an extraordinary ability to transform itself into a special branch of popular art (see POPULAR ARTS).

(R.McMu./Ed.)

Folk literature

Folk literature, as mentioned in the introduction, may also be called folklore. It is, in fact, the lore (traditional knowledge and beliefs) of cultures having no written language, and is, by definition, transmitted by word of mouth. It consists, as does written literature, of both prose and verse narratives, poems and songs, myths, dramas, rituals, proverbs, riddles, and the like. Nearly all known peoples, now or in the past, have produced it.

Until about 4000 BC all literature was oral; but beginning in the years between 4000 and 3000 BC writing developed both in Egypt and in the Mesopotamian civilization at Sumer. From that time on there are records not only of practical matters such as law and business but increasingly of written literature. As the area in which the habitual use of writing extended over Asia, North Africa, and the Mediterranean lands and eventually over much of the whole world, a rapid growth in the composition of written literature occurred, so that in certain parts of the world, literature in writing has to a large extent become the normal form of expression for storytellers and poets.

Nevertheless, during all the centuries in which the world has learned to use writing, there has existed, side by side with the growing written record, a large and important activity carried on by those actually unlettered, and those not much accustomed to reading and writing.

ORIGINS AND DEVELOPMENT

Of the origins of folk literature, as of the origins of human language, there is no way of knowing. None of the literature available today is primitive in any sense, and only the present-day results can be observed of practices extending over many thousands of years. Speculations therefore can only concern such human needs as may give rise to oral literature, not to its ultimate origin.

The nature of oral traditions. Nor can any evolution in folk literature or any overall developments be spoken of explicitly. Each group of people, no matter how small or large, has handled its folk literature in its own way. Depending as it does upon the transmission from person to person and being subject to the skill or the lack of skill of those who pass it on and to the many influences, physical or social, that consciously or unconsciously affect a tradition, what may be observed is a history of continual change. An item of folk literature sometimes shows relative stability and sometimes undergoes drastic transformations. If these changes are looked at from a modern Western point of view, ethnocentric judgments can be made as to whether they are on the whole favourable or unfavourable. But it must be remembered that the folk listening to or participating in its oral literature have completely different standards from those of their interpreters.

Nevertheless, two directions in this continually changing human movement may be observed. Occasionally a talented singer or taleteller, or perhaps a group of them, may develop techniques that result in an improvement over the course of time from any point of view and in the actual development of a new literary form. On the other hand, many items of folk literature, because of historic movements or overwhelming foreign influences or the mere lack of skillful practitioners of the tradition, become less and less important, and occasionally die out from the oral repertory. The details of such changes have been of great interest to all students of folk literature.

Early development

The beginnings of written literature in Sumer and Egypt 5,000 or 6,000 years ago took place in a world that knew only folk literature. During the millennia since then written literature has been surrounded and sometimes all but overwhelmed by the humbler activity of the unlettered. The emergence of the author and his carefully preserved manuscript came about slowly and uncertainly, and only in a few places initially—the literary authorship that flourished in the Athens of Pericles or the Jerusalem of the Old Testament represented only a very small part of the world of their time. Nearly everywhere else the oral storyteller or epic singer was dominant, and all of what is called literary expression was carried in the memory of the folk, and especially of gifted narrators.

All societies have produced some men and women of great natural endowments—shamans, priests, rulers, and warriors—and from these has come the greatest stimulus everywhere toward producing and listening to myths, tales, and songs. To these the common man has listened to such effect that sometimes he himself has become a bard. And kings and councillors, still without benefit of writing, have sat enthralled as he entertained them at their banquets.

Cultural exchange in written and oral traditions. This folk literature has affected the later written word profoundly. The Homeric poems, undoubtedly oral in origin and retaining many of the usual characteristics of folk literature, such as long repetitions and formulistic expressions, have come so far in their development that they move with ease within a uniform and difficult poetic form, have constructed elaborate and fairly consistent plots and successfully carried them through, and have preserved in definitive form a conception of the Olympic pantheon with its gods and heroes, which became a part of ancient Greek thinking.

Not everywhere has the oral literature impinged so directly on the written as in the works of Homer, which almost presents a transition from the preliterate to the literate world. But many folktales have found their place in literature. The medieval romances, especially the Breton lays, drew freely on these folk sources, sometimes directly. It is often hard to decide whether a tale has been learned from folk sources or whether a literary story has gone the other way and, having been heard from priest or teacher or doctor, has entered oral tradition and has been treated like any other folktale or folk song. The unlettered make no distinctions as to origins.

Influence on modern literature

As the European Middle Ages lead into the Renaissance the influence of folk literature on the work of writers increases in importance, so that it is sometimes difficult to draw a sharp line of distinction between them. In literary forms such as the *fabliaux* there are many anecdotes that may have come ultimately from tales current among unlettered storytellers, but these have usually been reworked by writers, some of them belonging in the main stream of literature, like Boccaccio or Chaucer. Only later, in the 16th and 17th centuries, in such works as those of Straparola and Giambattista Basile, did writers go directly to folk literature itself for much of their material.

Since classical times composers of written literature have borrowed tales and motifs from oral narratives, and their folk origin has been forgotten. Examples abound in Homer and *Beowulf.* In their literary form these stories have often lived on side by side with tellings and retellings by oral storytellers. Modern examples of traditions so used are found in Ibsen's *Peer Gynt* and Gerhart Hauptmann's *The Sunken Bell.* Particularly frequent in all literature are proverbs, many of them certainly of folk origin.

In Finland a good example of the direct use of folk literature in the construction of a literary epic is seen in the *Kalevala,* composed by Elias Lönnrot in the 1830s, primarily by fusing epic songs that he had recorded from Finnish singers. The *Kalevala* itself is a national literary monument, but the songs Lönnrot heard are a part of folk literature.

Writers and songmakers have always used themes taken from oral legends and folk songs and in their turn have affected the traditions themselves. In recent years the cinema has presented old folktales to an appreciative public, and interest in folk songs especially has been stimulated by the radio and television. Inevitably this oral literature has become less truly oral, and much pseudofolk literature has been presented to the public, habituated as it is to the usual literary conventions.

Within urbanized Western culture it is clear that folk literature has been gradually displaced by books and newspapers, radio, and television. Persons interested in hearing authentic oral tales, traditions, or songs must make special efforts to discover them. There still exist isolated groups that carry on such traditions—old people, recent immigrant enclaves in cities, and other minority populations, rural or urban. Children are also important for the carrying on of certain kinds of oral traditions such as singing games, riddles, and dance songs. These go on from generation to generation and are added to continually, always within an oral tradition.

During the past few generations folk festivals have flourished. These have become almost worldwide and of the greatest variety. They are likely to revive older dances or bring in new ones from other countries, but they also have some singing and occasionally taletelling. Usually a genuine attempt is made to keep them within the authentic local tradition, and they have been a stimulus to the preservation of a disappearing phase of modern life.

If folk literature is actually dying out, the process is very slow. It is now, as it has always been, the normal literary expression for the unlettered of all continents.

CHARACTERISTICS OF FOLK LITERATURE

The most obvious characteristic of folk literature is the fact that it is oral. In spite of certain borderline cases it normally stands in direct contrast with written literature. The latter exists in manuscripts and books and may be preserved exactly as the author or authors left it, even though this may have happened centuries or even millennia ago. Through these manuscripts and books the thoughts and emotions and observations and even the fine nuances of style can be experienced without regard to time or distance. With oral literature this is not possible. It is concerned only with speaking and singing and with listening, thus depending upon the existence of a living culture to carry on a tradition. If any item of folk literature ceases to exist within the memory of man it is completely lost.

Effects of oral transmission

The speaker or singer is carrying on a tradition that he has learned from other speakers and he delivers it to a living audience. It may well be that his listeners have heard this material many times before and that it has a vigorous life in the community, and they will see to it that he does not depart too far from the tradition as they know it. If acceptable to the listeners, the story or song or proverb or riddle will be repeated over and over again as long as it appeals to men and women, even through the ages and over long geographical distances.

In some cultures nearly everyone can carry on these traditions, but some men and women are much more skillful than others and are listened to with greater pleasure. Whatever the nature of these tradition bearers, the continued existence of an item of oral literature depends upon memory. As it is passed on from one person to another it suffers changes from forgetting or from conscious additions or substitutions; in any case, the item changes continually.

The more skillful tradition bearers take pride in the exactness with which they transmit a tale or song just as they have heard it many years before, but they only deceive themselves, for every performance differs from every other one. The whole material is fluid and refuses to be stabilized in a definite form. The teller is likely to see places where he can make great improvements, and he may well begin a new tradition that will live as long as it appeals to other tellers. It thus happens that in nearly all cultures certain people specialize in remembering and repeating what they have heard. There are semiprofessional storytellers around whom large groups of people assemble in bazaars or before cottage fires or in leisure hours after labour. Some of these storytellers have prodigious memories and may with only slight variations carry on to a new generation hundreds of tales and traditions heard long ago.

Forms and functions

Certain bards and minstrels and songmakers develop special techniques of singing or of telling epic or heroic tales to the accompaniment of a harp or other musical instrument. In the course of time in various places special poetic forms have been perfected and passed on from bard to bard. Such must have been the way in which the remarkably skillful heroic meters of the Greek epics were developed.

A different kind of oral tradition is preserved by the ritual specialists: priests, shamans, and others who perform religious ceremonies and healing rites. Frequently these rituals must be remembered word for word and are not believed to be effective unless they are correctly performed. The ideal of such priestly transmitters of oral tradition is complete faithfulness to that which has been passed down to them.

Not least important of the many reasons for the existence and perpetuation of folk literature is the need for release from the boredom that comes on long sea voyages or in army camps or everywhere on long winter evenings. Some folk literature is primarily didactic and tries to convey to simple men the information they need to carry on their lives properly. Among some peoples the relation of man and the higher powers is of especial concern and gives rise to myths that try to clarify this relationship. Cooperative labour or marching is helped by rhythmic songs, and many aspects of social life give rise to various kinds of dance.

A great many of the special forms of literature now in manuscripts and books are paralleled in traditional oral literature, where history, drama, law, sermons, and exhortations of all kinds are found, as well as analogues of novels, stories, and lyric poems.

Relation to folklore and mythology

Folk literature is but a part of what is generally known as folklore: customs and beliefs, ritualistic behaviour, dances, folk music, and other nonliterary manifestations. These are often considered a part of the larger study of ethnology, but they are also the business of the folklorist. (For further discussion of this point, see above *Folklore as an academic discipline.*)

Of special importance is the relation of all kinds of folk literature to mythology. The stories of Maui and his confreres in the Pacific and of gods and heroes of African or American Indian groups have behind them a long and perhaps complicated history. This is especially true of the highly developed mythologies of India, and the Greek, Irish, and Germanic pantheons. All are the results of an indefinitely long past, of growth and outside influences, of religious cults and practices, and of the glorification of heroes. But whatever the historical, psychological, or religious motivations, the mythologies are a part of folk literature and, though traditional, have been subject to continual changes at the hands of the taletellers, singers of stories, or priestly conductors of cults. Eventually singers or storytellers of philosophical tendencies have systematized their mythologies and have created with fine imagination the figures of Zeus and his Olympic family and his semidivine heroic descendants. Though the details of these changes are beyond the scope of this article, stories of the gods and heroes and of supernatural origins and changes on the earth have played an important role in all folk literature.

TECHNIQUES OF FOLK LITERATURE

Since the tales, legends, and epic and lyric songs discussed here are a part of the experience of a preliterate group or at least of the essentially unlettered, they differ in many ways from literary works addressed to a reading public. Long forgotten are the person or persons originally responsible for the tradition that has resulted in examples of folk literature. Only the tale or song remains to be repeated and often changed by subsequent storytellers, singers, or bards. In the course of its history it is listened to by generations of the unlettered, and its success and its very survival depend on how well it satisfies their emotional needs and intellectual interests.

Since in essence all folk literature is oral and subject to its survival in the minds of men, it is full of devices to aid

Technique of repetition in folk tales

memory. Perhaps most common of all is mere repetition. Especially in folktales and epics it is common to hear the same episode repeated with little or no verbal change. As the hero encounters his successive adversaries the description changes only enough to indicate the increasing terror of the enemy, always leading to a climax and usually to the hero's success. These long repeated passages often enable the teller of tales or the singer of an epic to extend his performance as much as he desires.

Aside from repetition of entire episodes, folk literature of all kinds is filled with formulistic expressions. It may be the beginning or the ending of a folktale—the "once upon a time" or the "married and lived happily ever after" or sometimes quite meaningless expressions—or standard epithets attached to certain persons or places. These formulas are so characteristic of oral literature that an abundance of such commonplaces seems to be a guarantee of authentic oral origins even of a great epic.

These formulas are matters not only of words but of structure. The storyteller or singer has at his disposal a large variety of conventional motifs and episodes and may use them freely. How appropriately they are made a part of his composition depends on his skill, but his listeners are not likely to be very critical so long as he keeps them interested. Indeed it is remarkable that in spite of this apparent freedom of improvisation so many rather well-articulated plots have lived for centuries retaining all their essential features. It is this combination of a basic narrative type with a freedom of treatment within traditional limits that makes it possible to identify hundreds of versions of the same tale or song as they appear over long stretches of time and space.

Though much of narrative folk literature is frankly fictional and filled with unrealistic events, the successful storyteller or epic singer gives his story credibility by the use of realistic details. Often these are merely homely touches linking the never-never land of the tale or song to everyday life or emotions. For the unlettered listeners such realistic details may allow a stretching of the imagination to embrace a larger world. Heaven or hell it may be or kingly palaces where the peasant hero rules with a splendour only known to those who have never seen a court. Often these details are given only to ensure that willing suspension of disbelief characteristic of all fiction, but sometimes a realistic touch, even in the midst of weak motivation and violence, may give nobility to a mediocre tale or song.

Repetition, formulas both in words and in structure, realism enough to support the marvelous in tale or song, violent actions and simple strong emotions—these qualities are generally found in all folk literature. The varying demands of the listeners are all-important influences. In some cultures this implies that actions should be well motivated so that listeners may identify themselves with certain characters. But in others, such as in many parts of India and in many preliterate cultures, motivation is often weak or entirely lacking.

For lyric songs, proverbs, riddles, and charms (and often legends), the relation of artist and audience is of little importance.

REGIONAL AND ETHNIC MANIFESTATIONS

Ethnic variations in relating folktales

In many particulars of form and substance there will be found great variations in the ways folk literature is manifested. The interests of people in one culture may differ profoundly from those of people in another. One group may enjoy singing folk songs, another listening to romantic folktales, and a neighbouring group may even be concerned only with legends and traditions. This difference is often geographical, so that the student of folk literature in the Pacific islands who may later investigate a central African tribe will find a completely different emphasis in the two areas. These differences may well depend upon the varieties of religious concepts held by the group or its natural environment, whether islands or jungle or cultivated farm lands, or its stability or mobility. These characteristics are likely to become especially deep seated in groups that have been settled in one place over a long period of history. Frequently they may correspond to national frontiers, but more often they are aspects of the general culture of an area and may well be quite independent of political or linguistic boundaries.

The Russian epic songs are found only in Russia, but the wonder story such as Cinderella or Snow White is a part of the folk literature of a good portion of the world. The Navaho Indians of the southwestern United States place great emphasis on their remarkable chants and lengthy folktales. Their neighbours throughout the Great Plains tell many well-constructed unified stories but confine their rituals largely to the dance. In Europe the Irish excel in storytelling, both of legends and fictional tales, so that even today it has been possible to record a prodigious number for their national archive. But in England and Wales the folktale is little cultivated, preference having been given to legends and ballads. As expected, there is a contrast between the abundance of oral saints' legends in Spain and Italy and their rarity in Scandinavia. Finland, meeting place of Eastern and Western tradition, shows an abundance of nearly every kind of folklore. From eastern Europe to Central Asia the folk epic flourishes.

Tales and origin legends have been collected in great numbers from various parts of Oceania, where there is a common mythological background extending over enormous distances. Except for probable early contact by way of Indonesia, these folktales seem to show little Eurasian influence. In many parts of South America the merging of Iberian, Indian, and Negro materials seems almost complete.

The folk literature of the North American Negroes is in a state of continual change, reflecting their history. Much certainly goes back to Africa, usually by way of the West Indies, and much was borrowed long ago. But the Negroes have themselves in a truly oral fashion developed songs and stories, and particular music styles. Of very special character is the folklore of modern Israel. Jews coming from various lands to the East and the West have brought together folk literature from all these countries. Assimilation of this is a long task, and since divergent language backgrounds are unimportant for folktales, the problem is to absorb the great variety of forms.

Taken the world over, folk literature is found everywhere, though the emphasis differs from place to place.

MAJOR FORMS OF FOLK LITERATURE

Function of the folk song

Folk song. Some kind of singing is almost universal and it is probable that where there are no reports of it information is simply missing. Folk song implies the use of music, and the musical tradition varies greatly from one area to another. In some places the words of songs are of little importance and seem to be used primarily as support for the music. Frequently there are meaningless monosyllables and much repetition to accompany the voice or the musical instrument. In much of the world drums and rattles, beating time by hands or feet or the stroking of a harp give a strong rhythmic effect to all folksinging. In others, flutelike wind instruments or bowed fiddles of one kind or another affect the nature of the folk-song texts. In many places these apparently meaningless folk songs are of great importance, serving as excitement to war or love or as a part of religious or secular ritual. Through them the group expresses its common emotions or lightens the burden of communal labour. In certain preliterate groups, and sometimes elsewhere, folk songs are used for magic effects, to defeat enemies, to attract lovers, to invoke the favour of the supernatural powers. Sometimes the magic effect of these songs is so greatly valued that actual ownership of songs is maintained and their use carefully guarded. They may come to the owner in a dream or as the result of fasting or other austerities.

Even when folk songs are not used for such practical purposes but only for the pleasure of singing or listening, the greater part of the world uses them for the expression of ideas or emotions held in common by the group. Only in societies used to the songs of composers or poets does purely personal expression enter into the folk song. This is not frequent, and songs of this type are hardly to be distinguished from some of the simple lyrics of poets such as Robert Burns. Folk songs, essentially expressions of commonly shared ideas or feelings, are often trivial but sometimes they may be profoundly moving.

Narrative singing

The lyric folk song in one form or another is found almost everywhere, but this is not true of narrative singing. Unless the reporting of the activities of preliterate cultures has been very faulty, it would seem that the combination of song and story among these peoples has been rare, in spite of a wealth of prose narrative. On the other hand, in major Western and Asian civilizations the narrative song has been important for a long time and has been cultivated by the most skillful singers. In the course of time these songs of warfare, of adventure, or of domestic life have formed local cycles, such as the *byliny* of Russia or the heroic songs of Yugoslavia and Finland or the ballad tradition of western Europe and elsewhere. Each of these cycles has its own characteristics, with its distinctive metrical forms, and its formulas both of events and expression. Any reader of the Homeric poems will be aware of their essentially oral and musical nature, and all the early literary narratives of Sumer and the Near East suggest a long previous development of narrative singing.

Ballad. A special tradition of tales told in song has arisen in Europe since the Middle Ages and has been carried to wherever Europeans have settled. These ballads, in characteristic local metrical forms and frequently with archaic musical modes, are usually concerned with domestic or warlike conflict, with disasters by land or sea, with crime and punishment, with heroes and outlaws, and sometimes, though rarely, with humour. Despite a folk culture fast being overwhelmed by the modern world, these ballads are still being sung and enjoyed.

Folk drama. Belonging only remotely to oral literature is folk drama. Dances, many of them elaborate, with masks portraying animal or human characters, and sometimes containing speeches or songs, are to be found in many parts of the preliterate world. Though the action and the dramatic imitation is always the most prominent part of such performances, these may be part of a ritual and involve speaking or chanting of sacred texts learned and passed on by word of mouth.

The ancient Greek mysteries, as well as secret societies even down to the present, have retained this method of transmitting dramatically their traditions and their teachings and commentary. Some dramatic rituals indeed were not secret but part of a public cult. Thus in ancient Greece the feast of Dionysus led eventually to classical Greek drama, and in the Middle Ages the dramatic celebrations of the Christian Church developed into the medieval folk dramas and at long last into the literary drama of the Renaissance and later.

The medieval mummers' plays and their modern survivals, the Passion plays, the Mexican reenactment of historic scenes such as "The Moors and the Christians," and the modern pageants—all these are based on written texts, however crude, and are beyond the scope of this treatment (see RITES AND CEREMONIES and LITERATURE, THE ART OF).

Fable. Fables, whether of the well-known Aesop cycle, with animals acting according to their real natures, or those from India, where animals simply act as men and women, are literary in origin. But they have had an important influence on folk literature. In addition to appearing in written collections, a number of these are told by storytellers in many parts of the world. Such fables as "The Ant and the Grasshopper," with appropriate morals, have been frequently recorded along with oral tales and have undoubtedly served as models for new animal stories. Sometimes these new tales have eventually received literary treatment, as in the medieval "Reynard the Fox," and then been carried back around the world by storytellers. In such narratives the borderline between folk literature and other literary expression is impossible to draw.

Folktale. The oral fictional tale, from whatever ultimate origin, is practically universal both in time and place. Certain peoples tell very simple stories and others tales of great complexity, but the basic pattern of taleteller and his audience is found everywhere and as far back as can be learned. Differing from legend or tradition, which is usually believed, the oral fictional tale gives the storyteller absolute freedom as to credibility so long as he stays within the limits of local taboos and tells tales that please.

A folktale travels with great ease from one storyteller to another. Since a particular story is characterized by its basic pattern and by narrative motifs rather than by its verbal form, it passes language boundaries without difficulty. The spread of a folktale is determined rather by large culture areas, such as North American Indian, Eurasian, Central and South African, Oceanic, or South American. And with recent increasing human mobility many tales, especially of Eurasian origin, have disregarded even these culture boundaries and have gone with new settlers to other continents.

Variety of types

In many preliterate cultures folktales are hardly to be distinguished from myths, since, especially in tales of tricksters and heroes, they presuppose a background of belief about tribal origins and the relation of men and gods. Conscious fictions, however, enter even into such stories. Animals abound here whether in their natural form or anthropomorphized so that they seem sometimes men and sometimes beasts.- Adventure stories, exaggerations, marvels of all kinds such as other world journeys, and narratives of marriage or sexual adventure, usually between human beings and animals, are common. Much rarer, contrary to the views of earlier students, are explanatory stories. Tales of this description are especially characteristic of Africa, Oceania, and the South American Indians.

In much of the world, especially Europe and Asia, the folktale deals with a greater variety of incidents than just described. In the course of time folktale scholars have given most attention to this area and have classified these stories so that the vast collections of them in manuscripts or books can be referred to with exactness.

All readers of such collections as those of Grimm will easily recall examples of tales of speaking animals. These may be old Aesop fables or parts of the medieval Reynard epic, but most of them are based on some ancient oral tradition. Such animal stories are especially numerous in eastern Europe. But better known perhaps are the ordinary folktales that deal with human beings and their adventures. For these tales, usually laid in a highly imaginative time and place—a never-never land—and filled with unrealistic and often supernatural creatures, there exists no good English word, so that usually scholars use the German term *Märchen.* Here belong "The Dragon Slayer," "The Danced-Out Shoes," the "Swan-Maiden" tales, "Cupid and Psyche," "Snow White," "Cinderella," "Faithful John," "Hansel and Gretel," and their like. Here also belong certain stories with religious or romantic motivation and tales of robbers and thieves—"Peter at the Gate of Heaven," "The Clever Peasant Daughter," "Rhampsinitus."

Jests and anecdotes

A major division of this classification of tales deals with jests and anecdotes. Examples are the many stories of numskulls, of clever rascals, and tall tales filled with exaggerations or lies. Finally come formula tales like "The House that Jack Built."

Among jokes and anecdotes a number are risqué or actually obscene. The indexes of the classification have included only those occurring in the published regional surveys. These surveys, and the books and manuscripts on which they have been based, have been subject to severe editing in order to avoid social or even legal offense. Some of the older anthropologists thought to avoid the eyes of the nonscholar by writing such tales in Latin, but a newer generation is much less squeamish. Folk stories now appear in print covering the gamut of the erotic—tales of seduction, realistic descriptions of normal or abnormal sexual activity, and scatological stories of great indecency.

This index of tale types fits the region for which it was planned and is constantly being improved and expanded, but it was never designed to cover the world. The Eurasian types are usually recognizable in any part of the globe and for them this type index is valuable. But for use with stories on a worldwide basis something less formal is needed, a classification of the possible or likely narrative motifs, minute or extended, and wherever found. Such a motif index has in fact proved useful outside of the Eurasian area, wherever comparative studies are undertaken, for parallels or analogues in simple motifs occur even in far distant places, often presenting extremely puzzling problems.

By use of such indexes and from the labours of many scholars, much material for examination of the folktale is available. These studies have been pursued since the 18th century, though until about 1900 most of them were premature attempts to answer the general question of where folktales come from. Eventually it became clear that no satisfactory solution is available, but that every tale has its own history and can be studied only with laborious attention to detail.

Folktale scholarship

In contrast to a literary story, with its standard text and author living in a definite time and place, the folktale is anonymous. Its originators have long been forgotten and it exists in many versions, all equally valid. Instead of being fixed like a literary document, it is in continual flux. But with hundreds of versions of a particular tale available for study it is possible to establish certain norms of plot structure and to point with some assurance to the varieties of subtypes that give clues to its life history. Such an analytical study of these hundreds of versions usually results in some hypothesis about the original form of the plot and the passage the tale has taken through time and space. In this way some 30 or 40 of the more complicated stories have been studied.

These geographical and historical investigations depend on the fact that the plot of the tale is complex enough to admit of really analytical study. For simpler stories and anecdotes scholars have had to be content with less exact methods, usually resulting in nothing more than accounts of their distribution and the known facts of their history.

Most of the attention of students of folktales during the 20th century has been given to historical questions and to preparing the apparatus for studying them—collecting, with ever improved techniques, arranging and archiving materials from manuscripts or books, and indexing types and motifs, so as to make collections even in remote or difficult idioms available to the serious investigator. But the folktale also has given rise to studies that are not strictly historical.

The attempts during the 19th century to find hidden meanings in tales were generally based upon the theory that they were broken-down myths and had lost their original meanings through linguistic misunderstanding. The result was that this "original meaning" was always found to be some conflict between weather or seasonal phenomena (winter: summer; clouds: sunshine; etc.). This type of interpretation has now generally gone out of fashion and has given place sometimes to explanations based upon ancient rituals or to some variety of psychoanalytic treatment. Though both of these possible sources of folk literature merit examination, the resultant interpretations have usually been merely astonishing to those acquainted with the actual history of the tales studied.

A much more fruitful approach to an investigation of folktales has been the studies of the tellers of stories and their audiences. From these has come an appreciation of the way in which folk literature is carried on in a tradition. A great deal more may be expected from such investigations, usually based on an intimate knowledge of the living lore of a single people.

Structural studies, especially of the folktale, have been engaging the attention of more and more scholars. Though particular plots may occur over large parts of the world, the form and literary style of the narrative is likely to be traditional within certain historical or geographic limits. The direction and strategy of these studies of structure are still unclear, but progress is being made.

Legend and tradition. Generally folktales are considered both by tellers and listeners as purely fictional. The line, however, between belief and unbelief is vague and varies from culture to culture and even from person to person, and even in the most sophisticated societies legends of strange things from the past or present continue being told and are usually believed.

Credibility of the legends

Stories about marvelous creatures are worldwide. Often these are merely mentioned or described and the belief in their existence is taken for granted. Frequently, however, there are circumstantial accounts of meetings with them, which result in adventures pleasant or distressing. With such creatures it is sometimes hard to tell whether we are dealing with a fictional story such as that of the dragon slayer of the typical European fairy tale or with a legend actually believed, such as that of St. George and the dragon. Though the folk in all parts of the world handle these stories with varying degrees of belief, there exists everywhere a remarkable resemblance among these supernatural creatures. The dragon, for example, in something of its characteristic serpent or crocodile form, is of great importance in China as well as in Europe and is represented in both places as a guardian of great treasure. Hardly less well known is the unicorn, and various combinations of man and beast such as the centaur and the minotaur, or the combinations of man and dog, have been a part of the legends of the Old World and occasionally of the New. Giant birds carrying men off in the claws, the phoenix reviving from its own ashes, flying horses carrying men through the air, sirens, mermaids and mermen, and unbelievable creatures resembling these appear in traditions all over the world. There are treasure animals of all kinds, not only the goose that lays the golden egg but the cow that furnishes treasure from its ear. The horse may warn the hero of danger or may determine which of two roads he should take. Important building sites are said to have been determined by the actions of a wise animal. Speaking animals, of course, figure prominently in all folk literature and even in such literary forms as the fable. Animals may speak to each other on Christmas Eve, or they may have governments and elect kings or celebrate weddings. These are only a few of the traditions current with a large part of mankind.

The relation between the animal and the human is very close in all folk literature. In the preliterate cultures of the American Indians, the Pacific Islanders, or the Central Africans, the culture heroes who are responsible for the good and the bad in the life of the tribe may upon one occasion appear as animals and upon another as men. Such was true of the ancient gods of Egypt or Greece. The question whether Coyote of the American Indian tribes is an animal or a man apparently makes no difference to those who tell stories about him.

Supernatural creatures in legends

Aside from these semidivine creatures, now animal or bird or man as they wish, supernatural and ill-defined creatures, much more difficult to visualize, are also common. Fairies or their counterparts appear in the legends of a good part of the world. It is hard to define them, for in one place they will appear in full human size, in another as little creatures inhabiting mounds or caves or living under the roots of trees. In some countries they are benevolent creatures, helpful to men and women. They reward human services but punish misdeeds. They marry or consort with human beings. In some traditions they are malevolent creatures, and meetings with them always bring disaster or bad luck. Almost every country has produced its own variety of helpful and harmful creatures. Stories of the activity of witches and devils, or water spirits and the supernatural guardians of mountains or trees vary in details from land to land, but many of the incidents related about them are easily transferred from one to another. Stories of visits to quite other supernatural realms, fairyland, for example, may be told in all their details in Russia or Greece. Giants are usually considered to be ogres of one kind or another but they may also be considered the most stupid of all beings and may be the subjects of hundreds of numskull anecdotes. Underground creatures like the dwarfs in "Snow White" are usually helpful and kindly, but other underground creatures bring only disaster.

The widespread belief in the return of the dead has resulted in many stories of encounters with ghosts or of actual resurrection. These stories differ greatly in various parts of the world and are much influenced by the current religious ideas. It is likely that in the whole world of traditional literature the belief in ghosts has survived longest.

Historicity of some legends

Traditions of historic characters have a tendency to repeat themselves from land to land and although they are told as facts may form as definite patterns as any fictional folktale. Such stories as Joseph and Potiphar's wife or the exposure and ultimate return of the hero appear in many places. The expected return of King Arthur from Avalon or of Barbarossa from his cavern are only two examples of a widespread motif of this kind.

It is difficult and perhaps impossible to distinguish the explanatory legend from the myth. Tales explaining the origins of customs or of the shape or nature of various animals and plants, of such distant objects as the stars, or even of the world itself often ascribe such origins to the action of some ancient animal or to some magic transformation. These are often connected with stories of the gods or demigods and may even be a part of the religious beliefs of those who tell them.

Generally, legends and traditions of this kind are simple in their form and contain only a single motif or at most two or three. The problem of proper classification for the purpose of studying these has proved very difficult, for while the materials of these legends and traditions show many interesting parallels and resemblances, they vary greatly from place to place. The relation of these stories to actual history, to mythology, and to the fictional folktale is of much interest to students of folk literature.

Proverbs, riddles, and charms. Three of the shorter forms of folk literature—proverbs, riddles, and charms—are not confined to oral expression but have appeared in written literature for a very long time. The proverb that expresses in terse form a statement embodying observations about the nature of life or about wise or unwise conduct may be so much an oral tradition as to serve in some preliterate societies as a sanction for decisions and may even be employed as lawyers employ court precedents. In literature it dominates certain books of the Old Testament and is found even earlier in the writings from Sumer. There has been a continual give and take between oral and written proverbs so that the history of each item demands a special investigation.

Proverbs and riddles in preliterate societies

While the proverb makes a clear and distinct statement, the purpose of the riddle is usually to deceive the listener about its meaning. A description is given and then the answer is demanded as to what has been meant. Among examples in literature are the riddle of the sphinx in Sophocles and the Anglo-Saxon riddles, based on earlier Latin forms. In oral literature the riddle may be part of a contest of wits. But even if the answer is known, the listeners enjoy hearing them over and over. In Western culture the riddle is especially cultivated by children.

Charms, whether for producing magic effects or for divining the future, also exist in folk literature as well as in the well-known Anglo-Saxon written form. The study of these extends over all parts of the world and back to the earliest records.

Children's use of folk literature. As a part of their play activities children not only play old games but repeat counting-out rhymes and retain play-party songs that have long ceased to be a part of adult activity in Western culture. Although the knowledge of those matters is available to children in their books, in actual practice it is passed on by word of mouth or by imitation, and the tradition may spread from school to school over a continent with great rapidity (see LITERATURE, THE ART OF).

STUDY, COLLECTION, AND PRESERVATION

As abundant as folk literature is and has been, its investigation has been seriously undertaken only within the past two or three centuries. The principal difficulty has been the assembling of material on which to base such studies. Its very oral nature makes it impossible for one man to be acquainted at first hand with more than an extremely small part of this activity. It is only when some sort of written record has been made of the oral material that any general studies are possible.

For the still unlettered peoples, the reports of ethnologists and anthropologists, as a part of their general studies of the cultures of widely distributed groups, have often given good accounts of folk literature and have frequently furnished texts of material they heard. Though these reports are extremely uneven and often fragmentary, they do give a sampling of the literary expression of many and diverse parts of the earth.

When attention is shifted to the ancient world before the use of writing, scholars are almost entirely dependent on analogies from the unlettered groups just mentioned. It will never be known what tales were told or what songs were sung by the builders of the Egyptian Pyramids or the temples in Sumer, but it seems fair to assume that even then these peoples were not silent. Of course it must be remembered that they did eventually develop a written literature, so that the analogy with modern unlettered peoples may not be completely valid.

For folk literature since the development of writing, scholars are dependent on several things. There may be specific references in literary documents to the existence of particular tales or songs and often to their manner of production. The Old Testament is a good source for these, and both the *Odyssey* and *Beowulf* contain good pictures of the performances of folk minstrels and bards.

Many collections of folktales and legends, of lyric and heroic songs, and of riddles and proverbs have been recovered directly from popular tradition within the past three or four centuries. When the collection of this material began it was nearly always rewritten in the prevailing literary fashion. Excellent examples of such rewritten tales will be found in the collections of Giambattista Basile (1634–36), Charles Perrault (1697), and various German writers such as Johann Karl August Musäus and Clemens Brentano in the 18th and early 19th centuries. The Brothers Grimm with their *Kinder und Hausmärchen* (1812–15) have as their ideal the exact recording of tales as heard from oral tellers, though it is clear that many stories in their famous work are not folk literature at all. In the same way, collections of folk songs and ballads were severely edited well into the 19th century.

Partly as a result of the Romantic movement in literature and partly of the interest in primitivism and the common folk, the recording of all sorts of songs and oral tales since about 1800 has been phenomenal. More and more the attempt has grown to recover material as it actually exists. Many thousands of volumes are to be found in great libraries that give a good sampling of folk literature in all parts of the world. The last century has also seen the development of large regional or national archives, many of them containing hundreds of thousands of items available for study. All of these books and manuscripts have become increasingly valuable as the techniques of collecting have progressed from casual longhand notes and rewritings through various stages to mechanical recording on discs and tapes.

Preservation of folk material

With mechanical recording it has been possible to assemble properly attested folk literary material from all parts of the world. This improved collecting has proceeded at an impressive pace and makes possible comparative studies of all kinds, based on the oral record.

As for the folk literature of peoples predominantly unlettered, these greatly expanded bases for study have brought out not only the characteristics found everywhere but have pointed up the differences found from place to place. Generalizations formerly accepted have to be reviewed in the light of these differences. With increased collecting, for example, do the likenesses or unlikenesses of American Indian tales and legends become more manifest? Does folk literature in a certain part of the world follow culture areas or language boundaries or some other principle? Such problems can now be investigated with the assurance that modern collectors have made every effort to record the oral tradition as it actually exists.

Much the same may be said of the 20th-century folk literature that exists among literate people side by side with written works. The collecting has improved both in quantity and quality. And not only have libraries been receiving new books of folk literature collections from interested persons everywhere but these collectors are better trained and equipped. The greatest improvement, however, in the study of folk literature transcribed in writing has been the development of folklore archives, of which a large part are concerned with various kinds of oral literature. These are growing rapidly, are scattered over much of the world, and are becoming well indexed and accessible.

(S.T./Ed.)

Folk music

Typically, folk music, like folk literature, lives in oral tradition; it is learned through hearing rather than reading. It is functional in the sense that it is associated with other activities. Primarily rural in origin, it exists in cultures in which there is also an urban, technically more sophisticated musical tradition. Folk music is understood by broad segments of the population, while cultivated or classical music is essentially the art of a small social, economic, or intellectual elite. On the other hand, that widely accepted type of music usually called "popular" depends mainly on the mass media—records, radio, and television—for dissemination, while folk music typically is disseminated within families and restricted social networks. (For further discussion of the differences between popular music and folk music, see POPULAR ARTS.) But the introduction of songs from folklore into the mass media blurs the distinction, and folk music in earlier times may be discussed separately from that of the period after World War II. Moreover, while folk music as defined above exists in all cultures in which there is also a cultivated musical tradition, such as Japan, China, Indonesia, India, and the Middle East, the usefulness of the concept varies from culture to culture. It is most convenient as a designation of a type of music of Europe and the Americas.

ORIGIN, FUNCTIONS, AND TRANSMISSION

Perhaps the most important characteristic of a folk song is its dependence on acceptance by a community—that is, by a village, nation, or family—and its tendency to change as it is passed from one individual to another and performed. This process of cultural exchange is known as "communal recreation."

A piece of folk music is the property of the entire community. But contrary to beliefs promulgated in the 19th century, folk songs are normally created not by groups of people but by individuals. When it is first composed, each song is the work of one composer, though it is recreated constantly by the performers who learn and sing it. The composer may create new songs by drawing together lines, phrases, and musical motifs from extant songs, possibly combined with entirely new ones and with standard opening or closing formulas. In European folk music, a small number of tune types account for most of the repertoire. English folk music, for example, is believed to consist largely of about 40 "tune families," each of which descends from a single song. And the majority of English folk songs are members of only seven such tune families.

There is frequent interchange of tunes between neighbouring countries. A few tune types are found throughout the European culture area. Each country, however, tends to have a repertory of its own, with stylistic features as well as tunes that are not shared with neighbours. Textual types (such as ballad stories) are more widely distributed than tune types.

The 20th century has seen the decline of folk tradition in many areas, particularly those that became heavily urbanized and industrialized. From the Middle Ages until the 19th century, folk music probably had been distributed evenly throughout Europe and the Americas. After 1950, folk music was found most readily in areas that were not heavily industrialized, such as the isolated mountainous regions of North America or of Italy and in the countries of eastern and southern Europe. In the Americas, folk music of European origin became mixed with elements of non-Western music, especially African and (in Latin America) American Indian.

Much folk music can be said to be "functional" in that it is not primarily entertainment or of aesthetic interest but an accompaniment to other activities, particularly ritual, work, and dance. In a traditional folk society, music is a necessity in almost all rituals and festivals. The words of folk song can serve as chronicle, newspaper, and agent of enculturation. In modern industrial nations, folk music is perpetuated by ethnic, occupational, or religious minorities, among whom it is thought to promote self-esteem, self-preservation, and social solidarity. Such functions of folk music have been used by organizations advocating social change, such as the U.S. civil rights and trade unionism movements.

Variants in folk music

Folk music is usually transmitted by word of mouth, or oral tradition. This means that a folk song can change as a result of the creativity of those who perform it or of their particular musical style or of their faulty memory. As it is handed down from generation to generation a folk song develops additional forms, called variants, which may differ markedly from each other. For example, a song with four musical lines (*e.g., ABCD*) may lose two of these lines and take on the form *ABAB*. In turn, two new lines may be substituted for the initial two, giving it a form *EFAB*. Folk tunes also change when they cross ethnic or cultural boundaries. A German variant, for example, may exhibit characteristics of German folk music, while its variant in Czechoslovakia, although recognizably related, will assume the stylistic traits of Czech folk music. The degree to which songs change varies from culture to culture. In some, presumably those that value consistency and object to change, such as western Europe, songs change little and slowly. In others, such as Afro-American cultures, the opposite tendency is found.

In spite of its dependence on oral tradition, folk music tends to be closely related to music in written tradition. Many folk songs originate in written form. For many centuries, popular and classical composers have adapted folk music, and in turn, influenced the oral tradition. A modern analogue of written tradition, recording, substantially influenced the oral tradition, as folk singers could hear various arrangements of folk music in private and commercial recordings. Thus, the transmission of folk music has not been an isolated process but one intertwined with other kinds of musical transmission.

GENERAL FORMAL CHARACTERISTICS

Composition. The composition of folk music differs little from that of popular and classical music, except that most folk songs are composed without notation. The relationships among the sections of folk songs and their scales and rhythms are also found in the other music of the same culture. Systematic improvisation as a method of composition is found only occasionally, as in the epic songs of eastern Europe. It is often difficult to ascertain whether the same composer created both words and music in a folk song, but, in many, they are known to come from different sources.

Among the most important genres of folk music are ballads, generally short narrative songs with repeated lines, epics (longer narratives in heroic style), work songs, love and other lyrical songs, songs of a ceremonial nature accompanying the life cycle of man or the annual agricultural cycle, songs accompanying games, and lullabies. These genres are distinguished usually in their texts, but in some cultures, also in their music. Instrumental folk music is most frequently an accompaniment to dance.

Melodic form. The typical melodic form of European folk music is strophic, that is, a stanza consisting of from two to eight lines (but most typically, four lines) is repeated several times in the song between successive stanzas of the text. The relationship among the lines of the repeated stanzas varies. For example, in English folk music, four lines with different content are common (*ABCD*), but forms whose endings revert to materials presented at the beginning are also common (*e.g., ABBA, AABA, ABCA, ABAB*). Similar forms are found in eastern Europe, where the use of a melodic line at successively higher or lower levels is also important. Thus, in Hungarian folk music, the form AA^5A^5A or AAA_4A_4 (the numbers indicating intervals of transposition) is common. In Czech folk music, AA^5BA is a common form. Despite the variety of arrangement of the musical lines of a song, the textual and musical lines nearly always coincide. In western European folk music, these lines are almost always of equal length; eastern European folk music frequently departs from this principle.

Exceptions to the strophic form

Among the exceptions to the strophic form are children's songs and ditties and epic songs. The former tend to be simple: they use limited scales and rhythms and small melodic range, and they may consist of only one musical line repeated many times. They appear to form an archaic stratum of European music and tend to be similar in musical content throughout the continent.

Epic folk singing is limited to a small number of folk traditions: Balkan, Finnish, and Russian, as well as non-European cultures. The tendency to repeat and vary a musical line many times is also found in epic singing, which is to some extent improvised.

The influence of popular music on folk music, which became very strong in the 19th and 20th centuries, has tended to limit and to standardize forms. The variety of melodic forms is greater, for example, in older English, Anglo-American, German, and Czech folk music than in later music.

Instrumental accompaniment

Most folk music is monophonic (that is, with only one melodic line), but polyphonic folk music, with several melodic lines, is found in some parts of the world. The accompaniment of melody by instruments is widespread as well, though all cultures have many songs that may be sung without it. The accompaniment of folk music in western Europe appears to have changed over the last thousand years. Originally, very simple, perhaps drone-like material was performed by string instruments such as harps, zithers, and psalteries. Later, simple harmonic sequences developed that were closely related to the practices of 18th-century classical music and involved a larger variety of instruments, including guitars, banjos, and string ensembles. The popular folk music of the modern cities embodies still more complex harmonic idioms.

Polyphonic vocal folk music is far more common in eastern and southern Europe than in western Europe. Styles vary from the simple two-voiced structures using drone-like techniques and parallel singing of the same tune at different pitch levels in Italy and the Balkans to the more sophisticated choral songs in three or four voices, found in Russia and Ukraine. Rounds are found throughout Europe. Heterophony—the simultaneous performance of variations of the same tune by two singers or by a singer and his accompanying instruments—is important among the southern Slavic peoples. Parallel singing is perhaps the most common type of folk polyphony: parallel thirds—that is, singing the same tune at an interval of a third—are found in Spain, Germany, Austria, the Czech Republic and Slovakia, and farther east; parallel fourths and fifths are sung in the Slavic countries. Instrumental folk polyphony is geographically more widespread than vocal. Bagpipes, for example, which use the drone principle, are ubiquitous in Europe. Scandinavian vocal music is largely monophonic, but complex styles of instrumental polyphony were developed in the repertoires of various types of fiddles, such as the Norwegian Hardanger fiddle.

It must be borne in mind that certain cultures, such as the British, the Hungarian, and the Cheremis, or Mari people of Russia, while having very little polyphonic folk music, have developed highly complex repertoires of monophonic folk song. Polyphony should not be considered an indication of an advanced state of art.

Rhythm and metre. In folk music, rhythm and metre largely depend on the metre of the poetry. Thus, in western Europe, where poetry is organized in metric feet, there is a tendency toward even isometric structure based on one type of metre—typically, $\frac{4}{4}$, $\frac{3}{4}$, or $\frac{6}{8}$, although $\frac{5}{4}$ also appears. In eastern Europe, generally, the number of syllables per line is the main organizing factor, regardless of the number of stressed syllables. Accordingly, the number of notes but not the number of measures is important, and repeated but complex metric units (*e.g.*, $\frac{7}{8}$, $\frac{11}{8}$, $\frac{13}{8}$, etc.) appear, particularly in Hungarian, Bulgarian, and Romanian songs.

Metre and singing style

Rhythmic structure is closely related to singing style. Singers in the older, ornamented styles frequently depart from rigid metric presentation for melismata (*i.e.*, a single syllable sung to a series of notes) and other expressive effects. Generally speaking, instrumental music is more rigorously metric than vocal. Nonmetric material, some of it consisting of long, melismatic passages, is also found in vocal and instrumental music in parts of Europe influenced by Middle Eastern music, such as the Balkan and Iberian peninsulas.

Scales. Generally speaking, the scales of European folk music fit into the diatonic tone system of European art music. On the whole, the scales of folk music in Asian high cultures are closely related to those consisting of two, three, or four tones, typically using major seconds and minor thirds. These scales are normally used in single-line songs, such as children's ditties, game songs, and lullabies, and they resemble the world's simplest music, that of certain tribal cultures. Among the most important scale types in Europe is the pentatonic, usually consisting of minor thirds and major seconds; it is found throughout the continent but especially in songs and song types not strongly influenced by the art music and popular music of the cities. Diatonic modes are the third important group. The modes most frequently used are Ionian (or major), Dorian, and Mixolydian, but Aeolian, Phrygian, and Lydian are found as well. The Ionian mode is most common in western and central Europe; others are found in eastern Europe, Scandinavia, and England (as well as in English-derived music around the world).

Scales with a predominance of small intervals close to minor seconds are found in the areas once influenced by Middle Eastern music.

INSTRUMENTS AND PERFORMANCE STYLES

Folk music instruments vary in type, design, and origin. They can be divided into roughly four classes.

Four classes of folk instruments

Among the simplest instruments are those that European folk cultures share with many tribal cultures throughout the world. Among them are the following: rattles; flutes, with and without finger holes; the bull-roarer; leaf, grass, and bone whistles; and long wooden trumpets, such as the Swiss alpenhorn. These instruments tend to be associated with children's games, signalling practices and remnants of pre-Christian ritual. They evidently became distributed throughout the world many centuries ago.

A second group consists of instruments that were taken to Europe or the Americas from non-European cultures and often changed. Among them are bagpipes, the folk oboes of the Balkan countries, the banjo, the xylophone, and folk fiddles such as the Bulgarian one-stringed *gusla.*

Another group consists of the instruments developed in the European folk cultures themselves from simple materials. A characteristic example is the *Dolle,* a type of fiddle used in northwestern Germany, made from a wooden shoe. A more sophisticated one is the bowed lyre, once widespread in northern Europe but later confined mainly to Finland.

The fourth group that is of great importance comprises instruments taken from urban musical culture and from the traditions of classical and popular music and sometimes changed substantially. Prominent among these are violin, bass viol, clarinet, and guitar. In a number of cases instruments used in art music during the Middle Ages and later, but eventually abandoned, continued to be used in folk music into the 20th century. Examples include the violins with sympathetic strings found in Scandinavia (related to the viola d'amore) and the hurdy-gurdy, still played in France, and related to the medieval *organistrum.*

The manner of both vocal and instrumental performance of folk music may vary greatly. In general, they differ considerably from Western art music. The sometimes strange, harsh, and tense voice in folk song is no more or less natural—or intentional—than the vocal style of formally trained singers. The manner of singing and the tone colour of instrumental music are among the most important characteristics of folk music. They are less subject to change over a period of time and less subject to influence than other characteristics of music such as scale, rhythm, and harmony.

Speaking very broadly, European folk music is sung in one of two styles, named *parlando-rubato* and *tempo giusto* after studies of east European folk music by the eminent Hungarian composer Béla Bartók. The first style, *parlando-rubato,* is probably older. Stressing the words, it departs frequently from metric and rhythmic patterns and is often highly ornamented. The second style, *tempo giusto,* follows metric patterns more precisely and maintains an even tempo. Both styles are found in many parts of Europe and in European-derived folk music. Using other criteria, the contemporary U.S. folk specialist, Alan Lomax, found three main singing styles in Europe and the Americas. The "Eurasian," found mainly in southern Europe and in parts of Britain, is tense, ornamented, and essentially associated with solo singing. The "Old European," found in central Europe and parts of eastern Europe, is more relaxed. Produced with full voice, it is often associated with group singing in which the voices blend well. The "modern European," found mainly in western European singing of more recent materials, is something of a compromise between the other two styles.

Before the 20th century members of a community probably tended to sing very much in the same style. In the 20th century—probably because of the influence of popular music, radio, and records—folk singers began to develop intensely personalized repertories and ways of performing, as may be seen in the work of popular folk singers.

In the Americas, the influence of African performance practices on Afro-American, as well as other folk music, has been important. Among these are the imaginative use of vocal tone colours, antiphonal and responsorial techniques, and complex rhythmic patterns.

RELATIONSHIP TO OTHER MUSIC

The relationship of folk music to art music became a topic of interest in the late 18th century when Western intellectuals began to glorify folk and peasant life. Folk music came to be venerated as a spontaneous creation of peoples unencumbered by artistic self-consciousness and aesthetic theories and as an embodiment of the common experience of inhabitants of the locale. These traits make folk music a fructifying source for art music, particularly when it is intended to express a particular nation or ethnic group. Another theory is that folk music is not created by the folk but is popular music and art music that has "trickled down" to the folk and undergone various transformations (usually debasements) through oral tradition.

A viewpoint intermediate between these two positions has been widely held since 1950. Folk music is seen neither as merely debased art music nor as an essential component of art music. Rather, it is seen to have a symbiotic relationship to other music in the larger society of which the folk community forms a part. In Europe and the Americas the give-and-take between folk music and art music is well documented. Many folk songs collected in oral tradition have been traced to literary sources, often of considerable antiquity. Folk music has been consciously incorporated into European art music compositions throughout history, especially during periods of "renewal" such as the Renaissance, the late 18th century, and throughout the 19th and early 20th centuries.

Relation to popular music

Folk music is closely related to popular music in several ways. Societies possessing popular music also have a folk music tradition—or remnants thereof. The partial duplication of repertories and style indicates such cross-fertilization that a given song may sometimes be called either "folk" or "popular." With reference to music, the terms folk and popular are two points on a musical continuum, rather than discrete bodies of music. From a sociological viewpoint, however, folk and popular music have less in common. Unlike folk music, popular music is primarily produced by professionals for consumption by an urban, nonparticipating mass audience. The vital criteria of folk music (*i.e.*, oral tradition, communal recreation, etc.,) are not operative.

Folk and popular music tended to merge in the 20th century. As folk societies came increasingly within the purview of modern urban society, oral tradition was supplemented or supplanted by the radio and phonograph record. Some folk music thus transmitted maintains stylistic authenticity, but some assumes the characteristics of popular music. Much of what is called folk music in English-speaking countries is a subcategory within popular music. It is the product of urban professionals who appropriate authentic folk music styles for concert and recorded performances.

Relation to jazz and rock music

There has been some interaction between folk music and rock music, as the generic designation "folk-rock" indicates. Folk-rock arose in North America in the 1960s. In its texts, it is modern urban folk song, with topical subject matter, often on social and moral issues. Musically, however, it has the characteristics of rock in its electrified string band and percussion accompaniment. Other current music that mixes folk and popular elements includes: African high life, American jazz, rhythm and blues, country-western music, and many Latin American forms, such as the tango and bossa nova.

Relationships between church music and folk music must also be noted. Some church music derives from the application of religious texts to secular folk tunes. This practice may be seen, for example, in the hymns of the Protestant Reformation and in the revival hymns of 19th century American camp meetings, which were called "folk hymns" because of their origins and associations with folk-like groups.

There are many types of folk dance, some widespread throughout Europe, others peculiar to nations and regions, each with its typical musical style. Certain musical forms appear most typically in the folk dance music of various parts of Europe. Most prominent is a form type in which each line is repeated once, with a minor variation, usually at the end—*e.g.*, $A^1A^2B^1B^2C^1C^2$. Vocal dance music also exists, and in northern Europe even narrative ballads were used for dancing.

STUDY AND EVALUATION

Knowledge of the history and development of folk music is largely conjectural. Musical notations of folk songs and descriptions of folk music culture are occasionally encountered in historical records. Such records, however, show not so much the history of folk music as the history of ideas held by the literate classes about folk music. It is assumed that throughout history literate society has possessed a musical culture different from that of their unlettered contemporaries. Their reaction to folk music frequently was one of indifference and, occasionally, derision and hostility. In medieval Europe, under the expansion of Christianity, attempts were made to suppress folk music because of its association with heathen rites and customs. Uncultivated singing styles were denigrated; Thomas Aquinas expressed a common sentiment when he likened artless singers to beasts. Some aspects of European folk music, however, became assimilated into medieval Christian liturgical music, and vice versa.

History and development of folk music

During the late 15th and 16th centuries, the literate urban classes responded more favourably to folk music than they had in the medieval period. The humanistic attitudes of the Renaissance, such as the elevation of nature and antiquity, encouraged the acceptance of folk music as a genre of rustic antique song. Some music in Renaissance manuscripts is presumed to be folk song by virtue of its musical simplicity and the rural and archaic evocations of its texts. It may, of course, have incurred stylization and change. Renaissance composers made extensive use of folk and popular music. Typical genres include polyphonic folk song settings and folk song quodlibets, or combinations of familiar songs. Folk tunes were often used as structural and motivic raw material for motets and masses, and Protestant Reformation music borrowed from folk music.

Folk music seems to have receded somewhat from the consciousness of the literate classes during the Baroque period. Folk song material in the music manuscripts and prints of the priod is scarce, and there is less folk influence in cultivated music, with the notable exception of stylized dance-music forms.

During the late 18th century folk music again became important to art music, especially among the Viennese classicists. They incorporated folk tunes and the general style of folk music into their instrumental music. The growth of national historical consciousness and the idealization of the rural milieu led to the collection, preservation, and study of folk song in the late 18th and early 19th centuries. Folk song came to be considered a "national treasure" and of considerable artistic merit vis-à-vis cultivated poetry and song. National and regional folk song collections were published. Revitalization of folk music became a means of promoting nationalistic sentiment and a conservative ideology. Governmental encouragement of folk music became common after the early 19th century.

Scholarship. The search for origins and processes of development that motivated much 19th and early 20th century intellectual activity was reflected in folk music scholarship. Among the influences on research in folk music in the 19th century were anthropological concepts of cultural processes and the theory of evolution. Many scholars believed folk music to be a repository of archaisms—a legacy from which the prehistory of music, language, literature, and other cultural traits could be adduced. While later scholars concede that some traits of folk music may be centuries or even millennia old, they are less inclined to speculate on the age of archaic elements of folk music or to offer historical reconstructions other than tracing variants of individual songs or types of songs.

Scholars who specialize in folk music usually have training in ethnomusicology, a discipline concerned with elucidating music in a cross-cultural perspective. Research in the words of folk song remains the province primarily of folklorists and students of language and literature. Folk music theories are concerned mainly with how folk genres and styles and individual folk songs originated, and how, if, and why they change when diffused. Theories of folk music have been beclouded by the difficulties in recognizing, isolating, and defining a phenomenon as elusive and complex as folk music.

Contemporary scholarship

Since the last decade of the 19th century, folk music has been collected and preserved by mechanical recordings. The application of print and recording technology to folk music has promoted wide interest, making possible the revival of folk music where traditional folk life and folklore are moribund. Folk songs are frequently a part of public school music curricula; various clubs, organizations, and societies focussing in one way or another on folk music, often in conjunction with folk dance, have arisen; festivals of folk music and dance are an annual event in many communities throughout the world; conservatories of music have been established for the training of folk musicians, particularly in the Socialist nations; radio stations devote substantial portions of their programming time to the broadcasting of folk or folklike music—again, particularly in Socialist nations.

The literature on folk music is sparse in theoretical works, in historical studies, and in materials integrating and comparing the various styles of folk music in Western culture. There is a great deal of literature showing the relationship between folk music and cultivated music. Most plentiful, however, are collections of music and texts, particularly of individual countries or regions, and even of individual singers. These collections are useful for scholarly comparisons of melodies; they give an imperfect picture of performance practice, however, because Western notation cannot give a detailed description of all aspects of music. After World War II, the availability of commercial records did much to fill this gap, and archives of field recordings were developed at many institutions throughout the world. In the U.S., those of the Library of Congress and Indiana University are most important; national archives exist in most European countries, and particularly in Hungary, Czechoslovakia, Germany, and Scandinavia. Such archives provide ample research material for an enormous diversity of projects. Research has usually dealt with "authentic" (*i.e.,* older) material not heavily influenced by urban popular music and the mass media. Popular folk music has not been studied widely. Several organizations for the study of folk music exist, particularly the International Folk Music Council and the Society for Ethnomusicology. (B.N.)

Folk dance

Although the term folk dance is most commonly applied to the gay, recreational dances of various nationalities, its precise meaning is the subject of much debate among scholars and has not been fully resolved.

Furthermore, scholars and dancers differ in what they admit under the label of "folk dance." One may see folk dance as the traditional dances of a country that evolve spontaneously from the everyday activities and experiences of its people. Another may define it as embracing only dances with magical and economic functions, or as comprising all nonprofessional dances.

The discussions dwell upon the confusion between such terms and concepts as "folk dance," "primitive dance," "ethnic dance," and "stage dance" and on the distinction between folk dance and modern recreational forms of ballroom dancing. (This subject is also addressed in the article POPULAR ARTS.)

Remnants of primitive dance persist in Africa, Oceania, and South America, among peoples who have retained some degree of their traditional religion and ways of life. Such dance throws light on the origins of dance of the Western world. In its retention of its original functions, primitive dance is distinct from the dances of more developed cultures, which may fluctuate between ritualistic and recreational purposes.

Varieties of folk dance

The term ethnic dance seems flexible. Some authorities see no difference between the terms ethnic dance and folk dance. The eminent American dancer Ted Shawn, however, would have ethnic dance subsume folk dance as a subspecies. He considers pure, authentic and traditional racial, national, and folk dance to be "ethnic"; he calls the theatrical handling of them "ethnologic," and he refers to the free use of these sources of creative raw material as "ethnological." Although these distinctions are not hard and fast, they reflect the trend of much ethnic dance toward professionalization. In still another view, folk dance is the dance from which the art dance of a nation inevitably grows, both in technique and in spirit. This concept is particularly applicable to such nations and regions as Japan, India, and Andalusia, where art forms of the dance were a natural outgrowth of the traditional dances.

Purists are disturbed by a trend toward the deliberate "staging" of folk dances, and especially by their increasing professionalization: they might call the adaptations folkloric. Professional dance and secular folk dance have been distinguished as one might separate art from craft, even when the scenarios and choreography of modern dance and ballet adopt materials from folk dance or the larger field of folk culture. Most scholars, however, exclude from folk dance the dances of the commercial theatre, television, and film. Though they generally consider jazz dancing an American folk style, they would exclude formal choreographies in jazz style.

These selected points of view indicate the fluctuating boundaries of folk dance, especially in reference to its functions. Although patterns and movement styles are significant, the function and locale of folk dances have greatest weight in distinguishing them from primitive and theatrical manifestations. Frequently the dances of rural peoples reveal their ritual origins on certain occasions, though they also serve recreational purposes. The origins may be very ancient. Generally, but not always, dances favoured in urban centres have secular purposes and may be of recent, perhaps consciously creative, origin. As in the case of folk song, the origin need not be anonymous, though usually it has been lost in the passage of time. Folk dances have grown out of creative inspiration, and they continue to sprout from the imaginations of individuals and groups, people of all classes who sense the traditions and the aspirations of their environment.

NATURE AND FUNCTIONS OF FOLK DANCE

Functions. Many folk dances best reveal their ancient functions when performed in their native habitat. Outside this context, in a school gymnasium or on a stage, they lose their aura, but on the village green the British Morris dances and the Abbots Bromley Horn dance speak of renewed May Day vegetation and of Paleolithic elk worship. Again, some dances serve various functions. The Spanish Aragonese jota is best known as a rural entertainment for men and women, but it may enliven funerals or appear on American stages.

Dance as ritual and entertainment

The above British examples reflect the transition from pagan to Christian religions and, in more recent times, the change from the attitudes of village and agriculture to those of town and industry and the consequent changes in social relations. As the English scholar Douglas Kennedy pointed out, when primitive religion weakens, some of the

Fusion of function and art form

mystery and the magic departs from the dances that express it. The dancer becomes less a medicine maker than a performing artist as ritual changes imperceptibly into art. In short, man's social adjustment to the environment, for purposes of survival, created both the original dance rituals and their subsequent functional or formal changes. Vestigial animal dances echo ancient animistic rites. The Ainu tribes of northern Japan still mime bear and fox hunts, portraying the animals very realistically. In West Africa, an antelope hunt in dance has ritualistic overtones, while monkey mimes are for entertainment alone.

The Balkans and Central America represent a far-reaching example of adjustment and change. These far-removed parts of the world share ecological circumstances, notably a basically agricultural civilization. Geographically, both narrow into bottlenecks connecting two continents; both combine high and rocky mountain ranges with agricultural lowlands and uplands; both bulge into peninsulas rich in culture. Both have submerged their ancient religious customs to innovations, those of Roman Catholicism and, in the Balkans, of Islām as well. Yet both have maintained their ancient native customs with such compromises as those to the events of the Christian calendar, Christian names, or Islāmic styles. Recently both areas have been receptive to the influx of 19th-century secular European dance forms and have transmuted these importations to suit the native styles.

Combat and agricultural dances. In both areas three dance types show varying degrees of modernization. One type, which takes the form of combat, remains highly ritualistic, albeit with a mixture of pagan and Christian elements. A second, agricultural in function, involves more of the community than the combative type and fluctuates between celebrations of sowing and harvest and of social festivities. The third type, derived from central and western Europe, is completely secular and social.

Male combat dances of the Balkans echo ancient pre-Christian rites for initiation into brotherhoods, the heralding of spring and of animal fecundity, and healing. Fierce battles ensue at the seasonal rituals of the Macedonians, of the Slovenes, and of the Romanians. Animal maskers and buffoons enact resurrection dramas. Along the coasts of Croatia and Dalmatia the battling factions have, under Christian influence, been renamed Moors and Christians or Moors and Turks. These battle dances have related forms and styles in other European countries, from Spain to Great Britain. They also have relatives in Central America, where early Spanish missionaries introduced Moors and Christians to replace the earlier ritual combats of the Indian populations.

Rural celebrations of planting and of harvests feature communal round dances, such as the kolo of the eastern Balkan region, the *horo* of Bulgaria, the hora of Romania, and a variety of Greek chain dances. The celebrations include vestiges of ancient vegetation festivals, impersonations of fertility deities, and "rain magic." The same rounds, however, appeared also at weddings and other secular or semisecular gatherings. Such rounds survive in the mountains of Mexico as *mitotes.* Although they concluded most Aztec and Mayan ceremonies, they have become scarce since the Spanish Conquest. They are still performed to procure rain and an abundant harvest.

Polka- and waltz-based forms

Secular forms. Rural and urban gatherings include the social square dances and couple dances for men and women. Within the last century the Bohemian polka, the Austrian waltz, the Polish mazurka, and the Hungarian czardas have appeared in the northern Balkans. In Central America similar social and courtship dances have become increasingly popular. Each region has a version of the dances known as *jarabe* or huapango. The *jarabe tapatío* of Jalisco, better known as the Mexican hat dance, combines steps from many European nations. All regional dances use polka or waltz steps and European music. With their lively and showy styles, these couple dances are suited to stage performances and occur as such.

In other parts of the world, folk dancers are shifting from a man–deity and man–nature purpose to a man–man or male–female attitude. This is noticeable not only in adaptations of former dances of supplication but also in dances miming agricultural and other occupations, as the Polish sowing of rye and oats, the Hungarian haymaking, the Swedish flax reaping, the clothes washing of Denmark, and the spinning mime of Spain. Some of these occupational dances derive from enactments by medieval guilds or from the mime in medieval branles. They survive as entertainment in adult couple dances and in children's games, often in settings remote from their origin.

In the course of centuries, changes in the beliefs and in the methods of producing the essentials of life have produced numerous adjustments such as the adaptation of the calendar from a basis in agricultural ecology to a basis in Christian festivals and the resultant shifts in the organization of dance groups.

Occasions for dancing. Notwithstanding the trend toward sociable and theatrical objectives, many folk dances celebrate original festivals. In Europe and Europeanized America, however, they show many adjustments to the Christian feasts. In the Balkans, Austria, and other countries the long series of dances for renewed vegetation and life now celebrate Epiphany (Twelfth Night), Carnival, Easter, Pentecost, Corpus Christi, and St. John's Day (June 24). As noted previously, the midwinter dances emphasize male combat and animal impersonations, whereas the springtime dances dwell on new vegetation, in southerly climates on first fruits. Two festivals are particularly spectacular—Carnival and Pentecost.

Festival dancing

Carnival festivals of Europe and the Americas precede Lent, filling the three days before Ash Wednesday. In Austria they perpetuate many pagan dances, particularly in Innsbruck and Imst, with the masked and ghostly phantoms and witches and noisy processions with songs, bull-roarers, drums, and whips. In Spanish and Latin American villages the unruly characters enact a more orderly "combat of winter and summer," in the guise of the ancient Moors and Christians, with the obvious victory of summer. Devils and deaths (*diablos y muertes*) are also on the loose in the role of buffoons. Morality plays are relics of medieval ideology, with speeches in the local vernacular and decorous steppings of Sin, Death, the Devil, Pastorcitas (shepherdesses in white communion dress), and masked animals from the Garden of Eden or bears or tigers.

Urban carnivals bring out animal maskers, deaths, and devils, without ritual connotations in, for instance, Munich. The famous carnivals of Rio de Janeiro and New Orleans draw huge crowds of tourists to observe the masking, competitive parades of floats, and street and ballroom dancing. In the Brazilian medley the street and ballroom dances show interesting contrasts: the samba in the streets is ecstatic, improvisatory, and disorderly, whereas the samba of the ballrooms is more sedate and has set steps. Such urban carnivals have lost sight of the original ritual purpose.

On the other hand the observances of Pentecost, the springtime feast that falls 50 days after the Christian Easter, fit the dances into a framework that meaningfully combines Christian and pre-Christian, New and Old Testament, forms. The Jewish Shavuot festival follows by the same period the Passover, which often coincides with Easter. The Pentecost, known also as Whitsunday, has since AD 200 commemorated the descent of the Holy Spirit on the Apostles, and the Shavuot, originally a feast of thanksgiving for first fruits, has been associated by rabbis with the giving of the Law at Sinai. Both express the joyous resurgence of animal and spiritual powers and of new vegetation.

Harvest dancing

In the southerly climates the festival may already celebrate the first fruits. Everywhere Jewish celebrants bring offerings of fruits and flowers to the temple, with chanting and prayers. In Haifa, Israel, white-clad youths and maidens dance and sing. In the Balkans girls dance for Pentecost, and the community winds in snakelike kolos. In England the community circles around a tree, then around the church, or it holds a maypole dance. In some villages, such as Bampton-on-the-Bush and those of the Cotswolds region, "Morris men" dressed in clean white caper and leap in a procession or in double files, waving white kerchiefs or green branches. The dancers may have the company of clowns, a Jack-in-the-Green clad in greenery. In some English villages and in British-inspired American locations, such dances take place on May Day rather than Pentecost.

Agricultural festivals, especially harvests, may adjust their dates not only to the local climate but to the particular year's weather. The Iroquois Indians of New York State and Ontario adjust their calendar to the ripening of the crops of berries, beans, and corn. They may hold their thanksgiving rounds for green corn between the third week of August and the middle of September. The square dances of the American farmers were held on the occasion of husking bees—before combines took over the work—whenever the corn was ready. Farmers continue their square dances, or "country dances," in barns or in grange halls at odd times or even weekly. Their urban imitators perpetuate these dances assiduously when square-dance and folk-dance societies, often mingling the traditional American dances with those of immigrant peoples, meet in national halls or centres, school or college gymnasiums, or other locations. The gatherings of these enthusiasts and analogous groups on both sides of the Atlantic are legion.

Certain secular or semisecular celebrations adhere to a definite date. Such political holidays as the French Independence Day (July 14) and the Mexican national holiday (May 5) and Independence Day (September 16) feature regional dances outdoors and at indoor balls. The Guelaguetza at Cerro Fortín, Oaxaca, formerly a ritual festival, now combines religious and regional dances for the general public on July 16. Such festivals attract vast numbers of dance teams, native visitors, and tourists.

FORMS AND TECHNIQUES

Social roles in folk dancing

Organization of participants. Although attendance at such public fiestas is haphazard, the participants in many dance gatherings observe closely knit organization and definite rules for the individual's place in the community and in the communal dances. The men in European combat dances belong to a sworn brotherhood of ancient origin. The male and female members of a Mexican votive society, the Concheros, have an intertribal hierarchy paralleling that of the forces of the conquistador Cortés, headed by a *capitán general.* In second rank are the officials of each local group, first and second captains, sergeants, standard bearers, each with specific duties, followed by the common rank of *soldados* and, finally, such attendant characters as Cortés' interpreter-mistress Malinche, the devil, sorcerers, and mythological figures. At present they do not regulate their rituals according to the calendar, though their ancestors probably did.

Although such societies cut across family ties, other organizations are based on descent, especially among American Indians. Iroquois and Pueblo Indians group their clans into two moieties, or halves, of the entire social scheme, matriarchal and patriarchal respectively. In their ceremonies and social events the Iroquois stress the interaction of moieties, with the alternation of moieties in the dance file. However, the New Mexican Pueblos usually feature separate dances for the two moieties and even assign festivals of the two seasons to the summer and winter moieties.

Sex and age roles. These same tribal groups also observe strict regulations according to sex. Iroquois women manage the summer rites for agriculture; the men manage fall and winter ceremonies for animals and cures. Among the Iroquois as well as the Pueblo, men and women hold esoteric dances separately, or men occupy one-half of the dance line and women follow in the second half. In less sacred dances and always in social rounds men and women alternate. Observers report similar customs not only among the natives of the New World but also in the Old, as in Serbia and Great Britain. Men perform the traditional Morris and sword dances, but the sexes mingle in country dances, reels, and quadrilles. The solos in Scottish sword dances are traditionally male performances, but, as a nonauthentic deviation, girls may now execute the tricky steps of the dances.

The traditions of age grades are also becoming diluted. From Greece to New Mexico, almost universally, the older, experienced men and women are the leaders, while the children bring up the rear of dance lines as apprentices. Warrior societies of Great Plains tribes of the United States once observed strict gradations of dance rituals according to age. But these societies are all but extinct, and public war dances admit all ages of males, with females in the background. With the dissemination of folk dances into the schools, children are learning adult routines. However, in remote villages of Europe youngsters have their special dances, and adolescents may enter the adult circles modestly.

Individual and ensemble dances. Generally the individual is submerged in the larger society and must fit into the dance group harmoniously. Some peoples, the Pueblo Indians for example, uphold strict standards of restraint, and within the natural variations of greater or less energy, a member of a dance group should not show off. However, other peoples such as the Iroquois appreciate improvisatory clownery or virtuoso display by talented males. In the Balkans the male leader of a dance line may engage in acrobatics—crouches, leaps, or pivots—while the rest of the group adheres to thè traditional steps. In the Basque provinces of Spain, in the Ukraine, and in Poland male experts have the opportunity to display high kicks or spectacular leaps. The improvisations of these privileged experts have often led to the introduction of permanent new elements into the dances.

Styles of movement. Function, sex, and age all have an effect on a dancer's style of movement. Other psychological factors of group and individual temperament and mood have, for untold centuries, determined the quality and the type of steps and gestures. The climate and topography may have had an effect on the development of regional styles.

Carriage of the body

National and regional style. According to Douglas Kennedy, the ideal of English folk dancers is to hold the body in a straight line from head to toes, creating a vertical equilibrium that makes the dancer light on his feet. This uplifted carriage allows him to reach out and form the contact essential for a unified dance ensemble. This ideal would apply to many folk dance types of Europe, the United States, and Canada, and to some Asiatic round dances, but it does not fit the more dramatic dances of the British Isles nor myriad dances in other parts of the world. Even within England, Kennedy points out the frequently bent-up position and the power of male sword dancers.

In Spain the erect ease of Aragonese line dances contrasts with the swaybacked incisiveness of Andalusian flamenco dances. In Yugoslavia the eastern villages have acquired the vibrations of Turkish dancers, and gypsies use more undulating movements than the Serbs about them. In Asia such hill tribes as India's Todas circle with simple steps and an erect posture, whereas demon dancers of the Pariah caste stamp and leap, and the practitioners of the ancient *Nāṭya* style combine elaborate, symbolic hand gestures with body sways and stamps.

Although India's caste system has produced extreme contrasts, differences in occupation and social class have everywhere affected the spirit and quality of movement. During the late Middle Ages and Renaissance the courtiers who borrowed such rural dances as the branle and the bourrée watered down their rustic vigour. In 19th-century colonial California the descendants of upper class Spaniards performed the polkas, mazurkas, and waltzes with an elegance that contrasted with the rowdy renderings by the gold miners.

Variations by sex. In modern square dancing the difference between male and female styles is negligible, but in most folk dances the women move more gently than the men, with smaller steps, lower leaps, and less raising of the knees or feet. The women dancers have a more sinuous, alluring style in southern Spain; they spin gently in the Austrian and Bavarian *Schuhplattler* and the Caucasian *lezginka,* while the men jump, clap, and shout. Among American Indian tribes the women have a more subdued style and often special, tiny steps except in couple dances that have been adapted from the mainstream of Western social dancing.

Ecological influences. The setting affects the movement style. Joan Lawson suggests differences due to the natural

Influence of the physical environment

environment—a theory that will need more investigation. She maintains that in rich agricultural plains or river valleys, such as the Danubian Plains and parts of France, and Denmark, movements are accented downward as if the body were being drawn toward the soil. Dancers perform in large groups, using the same step, closely linked together by fingers, hands, elbows, or shoulders. By contrast, in mountainous areas there is a good deal of leaping and individual display, especially among the males.

Mimetic and abstract movements. Regional variations include preferences for mime or for abstract movements. India's folk dancers and, half a world away, those of Scandinavia favour mimetic gestures, respectively graceful and comic. Serbia's peasants are interested in purely decorative steps and Ireland's experts are fond of tricky solo steps or complex group patterns that are in no way imitative of outside phenomena. In general, the mime of folk dancers is stylized, having lost the realism of the primitive animal impersonators and of actors in folk dramas.

Opportunities for mimetic dancing are drastically reduced when the hands are required for other formal patterns of the dances. Most folk dancers use their hands and arms for contact in circles, lines, or couples; they wave kerchiefs, as along South America's Pacific coast; they swing soft balls in complex patterns, as in the *poi* dance of the New Zealand Maoris; the women swirl full skirts, as in Spain and Mexico; or everyone lets the arms hang loose or places hands on hips, thus emphasizing foot and ground patterns.

Stylized gestures and motions

In India, dance-dramas based on the life of the god Krishna (Kṛṣṇa) are enacted in Manipur by young women who use simplified gestures descended from the large, complex system of hand gestures known as mudras. The basic gestural symbols derive from the wrist position, the position of the palm, and the poses of the fingers. Each gesture has its prescribed musical accompaniment. A trembling leaf, for example, is symbolized by the *alapallava,* a rotation of the wrist accompanied by a folding and unfolding of the fingers. In Hawaii, a few older women can execute hula gestures clearly descended from the mudras, but younger dancers have diluted the tradition by introducing purely decorative gesture.

In Scandinavian countries male and female imitators of occupations likewise stylize their harvest motions. The youths who portray rough-and-tumble fights, as in the Swedish oxen dance, duel good-naturedly, pull each other's hair, and pretend to box one another's ears. In this last gesture, as in the German *Watschenplattler,* the aggressor merely pretends to touch his opponent, who claps his hands to simulate the blow.

Slavic men and some other skilled performers use steps recalling former animal mime, as the goatlike caper or cabriole, the pawing horse-step or pas-de-cheval, the side-kicking, cowlike rue-de-vache, and the feline pas-de-chat leap. But folk dancers of many nationalities exploit the imageless mazurka or variants of the polka, waltz, and twostep, all in appropriate rhythms. The walking, running, sliding, skipping, or jumping movements are so universal in folk dance that they cannot, by themselves, be considered mimetic.

On the one hand, line dancers of a single region may develop intricate variations of a basic step. Lawson identifies 15 ways of performing the basic kolo step, a step-to-the-side and close. The variants include gliding, swinging of the free leg, crossing, jumping. On the other hand, a widely disseminated step may appear in many forms in different regions. The triple-time waltz is step-together-step in Austria, with pivots at specific times. As the Mexican *atole* step it is forward-back-forward; in the Venezuelan joropo every first beat is heavily accented. As a ballroom dance it reveals diverse patterns: as a propelling step in Spanish and New Mexican quadrilles, a light-footed waltz may balance from side to side, progress forward or backward, or go round and round.

The type of step depends also on the purpose of the dance, whether a solemn processional or an exhibition of skill in leaps or crouches; on the sex or age of the various participants; and on the type of ground plan.

Ground plans. Simple circling leaves the dancer's attention free for elaborate steps, whereas complex ground plans take the mind away from stepping and necessitate the simplest kind of progression by walking or running. Throughout the world the erstwhile ritual dances may involve a simple run, as in the Iroquois corn and bean dances and the serpentine stomp that spread from the ancient Aztecs to Indian agriculturalists of the U.S. Choreographies may combine complexities of step, of rhythm, and of ground plan, like the "game animal dances" along the Rio Grande, but as a rule they emphasize one or another factor.

Serpentine and meander dance formations

The Balkan chain dances feature intricate steps and rhythms, but simple formation of closed or open circles. During closed rounds the men and women remain within the same spot as they inch along counterclockwise. Likewise, participants in French branles circle on location, usually clockwise—the typical direction of northwest Europe. In chain dances the circle is not closed. A leader guides the line, linked by hands or a prop, in meanders and spirals perhaps across open fields. On reversal a tail man will guide the meanders. Such serpentines, of ancient origin, are favourites in the Near East; throughout Europe, especially as the French farandole and the Catalan sardana; in North America, in both native and Europeanized dances; and in such parts of Asia as Manipur. They predominate among agricultural peoples, for they originated in chthonic symbolism.

A specialized form of meander is called the hey in England. Two lines of dancers weave past each other in opposite directions. In a circular fomation this is known as the square dance "Paul Jones" or, if the participants are attached by ribbons to a central pole, as a maypole dance. Here the two opposing groups are or should be male and female. The most elaborate form akin to the hey is the *kolattam,* a stick dance of South India. In the *pinnal kolattam* the dancers weave in and out, at the same time striking short sticks in precise patterns. (The intricacies were diagrammed by Hildegard L. Spreen: see Bibliography.)

Linear dance formations

Dances in two parallel lines have a more limited distribution. As in the case of rounds, the performers may start shoulder-to-shoulder or aligned in the same direction. The lines may cross over or circulate in opposite directions, or pairs of dancers can cross directly or diagonally. Morris dancers use a large vocabulary of interlacings, which resemble those of the American "Virginia Reel"; respectively, the participants are men only and men-and-women. Multiple parallel lines of men and women are customary in Southeast Asia and the South Pacific; Cambodian girls display elegant poses; Balinese men carrying spears mass together in the *baris* dance; and while executing the warlike gestures of the *peruperu,* Maori men remain in one spot.

As noted previously, ritual principles often dictate that in more sacred dances the sexes be separated, whereas in more secular dances they usually alternate or are aligned face-to-face. In modern folk dances, couples circulate within circular formations, as in Moravian rounds and American square dances, or in the extremely elaborate Irish reels of eight couples. In ballroom dances couples generally ignore any geometric designs, and individuals ignore the rest of the group.

In the "possession rite" of Ghana's Akhan society, circle dances by devotees, frenzy dances, and circling by everyone alternate with prayers, chants, offerings, and speeches. A similar structure is evident in the possession dances of Brazil and Trinidad and of the Christian Holiness services in the U.S.

Couples and solos. In the course of history the general trend, during secularization, has been toward increasing complexity, from round or double file to quadrilles, and then from cohesion to a breakup into couples and solos. This disintegration is distinct from the individualism that may be present in primitive dances, for there the soloist had a mimetically compulsive, even priestly, function and was the focus of group activity. Concurrent with the elaboration of patterns, the symbolism has been disintegrating. The vegetation symbols of meanders and arches have been lost, but the designs remain. Face-to-face formations and couple arrangements retain meaning as courtship actions, and despite the loss of the modern folk dancer's relation to, or attempt to act upon, the physical environment, the social contacts between dancers remain.

The type of ground plan affects the contacts between not only the dancers but also the dancers and the spectators. Square dances offer the maximum possibilities of intermingling within a formation, but they exclude spectators. Chain dances lack the give-and-take, but they may wind about or through the spectators, who may enter at any time. Contact, whatever form it may take, is essential to folk dance.

ACCOMPANIMENT TO THE DANCE

The evolutionary process in the relations between the dance and other arts is very similar to the development of the dance itself. From the nearly total integration of dance and life in primitive ritual to modern rock-and-roll, many factors—the passage of centuries, the change from animism to Christianity, the shift from hunting, agriculture, and handicraft to industrialization, the trend from country to city, from sanctuary to village green to stage—have exerted a profound influence on the totality of dance experience.

In the esoteric dance rituals of Australia, in the mythological dance enactments of India and Indonesia, in Nigeria and such of its distant New World derivatives as the vodun, dance is immersed in the larger drama of the rite. The symbolism of the movement patterns is locked into the symbolism of song texts, the traditional music, and the meaning of masks and costumes, not to speak of the setting in a sacred grove. Here and there the decorative invocations to animistic spirits have survived, mysteriously, in the masked animal ghosts of the Austrian Alps, as well as in the "game animal dances" of New Mexico's Tewa Indians. Perhaps these vestiges are not really folk dances. Perhaps folk dances—that is, dances of the people—do not require the integration of all of the arts for gatherings or programs.

Music. In general, the musical accompaniment to folk dances has persevered fairly well. In village and urban hall the devotees use the tunes intended for particular routines, though these tunes may be played on modern instruments. Morris dancers usually preserve the traditional order of a suite—Laudnum Bunches, Bean Setting, Rigs o'Marlow, Shepherd's Hey, Constant Billy. In the execution of isolated kolos, ländler, or country dances, natives and imitators fit the steps to traditional tunes, to live music, piano, or recordings, which may feature old-time clarinets, tabours, drums, and even band arrangements or accordions.

The coordination of tempo and rhythm between dance and music is rarely problematic. It is easy to follow the slow and the fast tempo of a set like the Norwegian *gangar* and *springar,* or the acceleration of an Israeli hora. It is easy to follow the metres of the polka, of the waltz with its accent on the first beat, or of the mazurka with its accent on the second, although the melody may have independent rhythms. It takes more skill to follow some of the Bavarian tunes that shift their metres, and it takes an expert to follow the unusual metres of Greek and Serbian dances, especially when the phrases of the tunes overlap the phrases of steps.

Self-accompaniment. It takes practice also to provide self-accompaniment in rhythm or melody. Rarely do folk dancers provide their entire self-accompaniment, as do the Mexican *viejitos* who play small stringed jaranas, or Hawaiian hula dancers who chant and shake rattles. Frequently, the dancers add percussive effects to the accompaniment by special musicians. They stamp on the ground, on the floor, or on a resonant platform with bare feet, boots, or high-heeled shoes, sometimes in complex counter-rhythms. Hungarian men click spurs; Russians click the heels of their boots as they leap. Austrian and Bavarian *Schuhplattler* males swat various parts of the anatomy in set rhythms. Sword dancers click swords: stick dancers click sticks in Spain, Portugal, England, Mexico, Brazil, and India. Andalusians punctuate their incisive foot rhythms with crisp sounds of finger castanets; Greek males click spoons in their *zabakelos;* and American Indians sometimes shake rattles. In such secular dances as the Cuban rhumba or Argentinian *carnavalito,* accompanists use rattles. Sound makers may be attached to the costume, as the bell pads of Morris dancers or the ankle bells of India's nautch dancers. In many parts of the world exuberant dancers dispense with instruments and clap or shout at specified times or whenever the spirit moves them. They may also sing to various instruments or without instrumental accompaniment.

Percussive effects produced by dancers

Song. Self-accompaniment by song is significant for several reasons. First, it is probably one of the most ancient forms of accompaniment because of the independence from any instruments. Second, it is aesthetically pleasing. Finally, the songs have texts of historical, sociological, or ecological importance. Such singing may be in unison, with women's voices an octave higher than the men's; it may employ harmonies characteristic of the region, with intervals of a third or a fourth, and it may involve antiphony between a leader and the dance group or two groups of dancers. Such antiphony occurs in widely separated parts of the world, frequently in connection with serpentine chain dances as in Manipur and in America's Southeastern woodlands. Frequently the responses use nonsense syllables, and they may involve gestural responses, as in the Cherokee "stomp dance" and its predecessor, the ancient Aztec serpent dance.

The song texts are varied. The most frequent topics are courtship, as in the "Llorona" of Mexico's Tehuantepec, or sheer joy, as in the German "Freut euch des Lebens." In the Faeroe Islands the topics are narratives from legends, which are mimed by the round dancers. Sometimes the topic refers to agriculture, as in the French Canadian children's round, "Avoine" ("good grain").

The previous remarks mentioned the sound-producing items of costumes, as boots and bells. Visually effective items worn by dancers include kerchiefs and female full skirts, which permit numerous manipulations. Other visual effects are the designs of regional dress in the various countries, from the flouncy flamenco skirts to the white trousers of sword dancers. In the United States square dancers sometimes affect full skirts for women and plaid shirts for men.

CONTEMPORARY TRENDS

Revivals. The revived interest in national folk dances is generally dissociated from tradition, unless a folk dance group has a leader with folkloric knowledge. Folk dancing inspires the weekly gatherings of groups in civic centres, colleges, and other centres, even the entire schedules of summer folk-dance camps. Congresses sponsored by the Folk Dance Federation of California produced a uniform repertoire for groups throughout North America. In addition, new immigrants introduced occasional new dances. Most of these groups dance for the sheer pleasure of dance, and more expert ensembles stage programs and enter contests, both in the New and Old World. But although such revivals and the consequent preservation of traditions were heartening and brought about good fellowship, healthful exercise, and, avowedly, international understanding, such dancing had no connection with the aboriginal purposes of folk dancing, which continued only in villages or on Indian reservations.

Role of costuming

The modern style of costuming is an exteme departure from the masks for spirit impersonators and the symbolic designs painted or woven on all costumes of the ritual dances. Such paraphernalia survived in some dances that straddle ritualism and folk dance, as the animal and corn dances of the Pueblo Indians. But the trend was increasingly toward contemporary dress. Even the Iroquois ritualists usually wore ordinary clothes. Members of folk dance clubs rarely wore traditional costumes at their informal gatherings, although these clothes were customary for staged programs.

As a contrasting trend, professional folkloric troupes exaggerated costume effects, doubled the volume of skirts, added spangles, and increased the instrumental volume and the tempo. Frequently the directors composed scenarios, as in the reconstructions of Aztec rituals by the Ballet Folklórico de México. Their spectacles have a great audience appeal, compensating in part for the nonkinetic and the prosaic in modern folk dancing.

Continuity and change. The folk arts are by and large expressive of traditions that are deeply rooted in the life-styles and in the social organizations of peoples and cultures throughout the world. But as those styles and organizations change over time, in response to environmental, economic, technological, and other factors, so do the concomitant artistic expressions evolve in terms of function, form, and mode of existence. But change has been brought about, too, by the creativity of individuals and of cohesive groups.

Influence on other forms of the dance

Professional dancers found folk materials a rich source of inspiration that they used in several ways. Authentic dances were intensified for the stage by such companies as the Philippine Bayanihan troupe and the Ceylon National Dancers. The sophisticated dance-dramas of India's Uday Shankar, who performed widely in the West, often contained folk dances. His work with the Russian ballerina Anna Pavlova in *Radha and Krishna* showed, too, the rich potentialities for East–West collaboration. A folk atmosphere can be evoked without using folk materials, notable in *La Malinche* by José Limón. Finally, seemingly incompatible styles were fused: Mary Wigman was among the first to blend the rather stark idiom of modern dance with the ornate and exotic styles of the Orient.

Although the origins of many traditional dances are lost in a nebulous past, the observed emergence of new forms may give clues to the age-old processes of change. Inspired individuals may have molded the patterns of the ancient round-dance figures much as numerous leaders of dance in the 20th century have invented variations on the steps or devised steps and patterns to fit new rhythms, passing on their innovations by teaching or imitation. Again, creators have developed entire new dance structures from traditional materials, as the choreographers of modern Israeli dances have done most skillfully.

Another inevitable process is that of crystallization. For various reasons—sanctity, nostalgia, or whatever—groups tend to maintain routines through time. But not forever. If a dance does not die of old age, of having totally outworn its function and of having a form or spirit out of tune with a new age, it will continue to gain new life from improvised variations on basic steps or ground plans or from conscious elaborations of its forms by professional directors of ethnic dance groups and programs. Such kinds of creativity, individual and group, contribute to that constant cycle of orderly change within traditional parameters which accounts for the rich variety of the dances of the people. (G.P.K./Ed.)

Visual arts of the folk tradition

In the broadest sense, folk art refers to the art of the people, as distinguished from the elite or professional product that constitutes the mainstream of art in highly developed societies. The term in this comprehensive context combines some quite disparate categories of art; therefore, as a workable field of art-historical study, folk art is generally treated separately from certain other kinds of peoples' arts, notably the primitive (defined as the work of prehistorical and preliterate peoples). Historically, the terms folk and popular have been used interchangeably in the art field, the former being specific in English and German (*Volkskunst*), the latter in the Romance languages (*populaire, popolare*); the term folk, however, has increasingly been adopted in the various languages, both Western and Oriental, to designate the category under discussion here.

Difference between folk and popular art

Currently, the term popular art is widely used to denote items commercially or mass produced to meet popular taste, a process distinguished from the manner of the folk artist, who typically creates by hand (or with limited mechanical facilities) within a prescribed tradition objects designed for use by himself or his own circumscribed group. The distinction between folk and popular art is not absolute, however: some widely collected folk art, such as the chalkwares (painted plaster ornamental figures) common in America and the popular prints turned out for wide distribution, may be seen as the genesis of popular art; and the products and motifs long established in folk art have provided a natural source for the popular field.

Although the definition of folk art is not yet firm, it may be considered as the art created among groups that exist within the framework of a developed society but, for geographic or cultural reasons, are largely separated from the cosmopolitan artistic developments of their time and that produce distinctive styles and objects for local needs and tastes. The output of such art represents a unique complex of primitive impulses and traditional practices subjected both to sophisticated influences and to highly local developments; aside from aesthetic considerations, the study of folk art is particularly revealing in regard to the relationship between art and culture.

As industry, commerce, and transportation begin to offer all people free access to the latest ideas, and products, a true folk art tends to disappear; the integrity and tradition that formed its inherent character decline, and the heritage of home-produced products is undervalued for the very qualities that made it distinctive. Subsequent revivals, extensively sponsored by organizations, craft groups, governments, or commercial enterprises, are no longer the same thing.

The recognition of folk art as a special category came about during the late 19th century and was at first limited to the so-called peasant art of Europe, the "art of the land." The new intellectual climate of the time, with a romantic value attached to the simple life and the "folk soul" and the increasing spread of democratic or nationalistic ideas, brought the art of the common people into focus. It was recognized that their simple tools, utensils, and crafts had aesthetic aspects. Prior to industrialization, such folk art was widespread throughout Europe, exhibiting almost everywhere local styles created by people who had no access to the products of the wealthy and who were engaged largely in agricultural, pastoral, or maritime pursuits. As sophistication advanced, localism began to break down along major routes, but the folk arts continued on the periphery, particularly in geographically isolated regions, where they had an opportunity not only to survive but also to elaborate.

Preservation of folk art

Having only limited contact with the outside world, the inhabitants preserved their traditions, art forms, and methods of workmanship over a long period and, at the same time, had to rely on their own invention to create new styles and products at need. These outstanding regional arts provide a well-defined core of material in the field of folk art.

As the early colonists emigrated to remote parts of the world, they, too, were isolated from the cultural developments of the homeland and forced to rely on their own skills for most of their products. The arts they took with them were transformed, and new arts emerged under the stimulus of a different environment and through contact with native cultures; the notable folk arts of the Americas were one result.

In time, it was recognized that the great Oriental civilizations, like those of Europe, also had two distinct forms of art—the elitist and the folk. As Oriental folk-art scholarship developed, the subject gained international footing.

While most scholars agree that a folk type of art has occurred at some time in many parts of the world (and may yet appear in newly developing countries), there are various areas in which such art has so far been ignored or has not been studied as a separate category. For instance, with the notable exception of Roman folk art, the folk distinction is not usually applied to the art of ancient civilizations nor to Islāmic or Western medieval art. The summary provided here is, therefore, necessarily concentrated on the more studied areas: European folk art of the 17th–19th century, colonial and postcolonial folk arts, and the folk art of certain major Eastern countries. In addition to the major folk regions, this article will deal with the categories, styles, content, and motifs of folk art.

PATTERNS OF DEVELOPMENT

The extensive studies of European and American folk art over the past century have revealed certain patterns of folk-art development. Though these patterns are subject to revision as the field expands or is refined, they provide a basis on which cultural variations and less widespread or random occurrences may be considered.

The utilitarian aspect of folk art. Typically, the people who created the art were immediately concerned with producing the necessities of life; as a result, the art is often described as predominantly functional or utilitarian, in spite of the fact that there are important categories that are definitely not utilitarian, such as the widespread miniatures created simply for pleasure. It is true, however, that much artistic effort was absorbed in meeting everyday requirements. In the folk group, in which occupations were often seasonal or dependent on weather and where people had to provide their own amusements, the creation of useful objects became also a leisure-time activity on which creativity was lavished; a shuttle might be transformed with carving or a chest with painted designs, and even the corset stay came to be an art form. For this reason, folk art is best studied (as is primitive art) with the entire handmade product included and attention devoted to its cultural as well as its aesthetic significance. It differs from the study of sophisticated art, in which there is a long-standing distinction between fine and applied arts and a tendency to exclude, or at least segregate, the utilitarian from more strictly aesthetic forms.

Folk art was not created for museums. Certainly, some was designed to endure, such as documents, family portraits, and gravestones; occasional types were made purely for display, such as the "show towel" of the Pennsylvania Germans and the sampler (a piece of needlework with letters or verses embroidered on it as an example of skill); and certain household treasures were preserved for generations. In general, however, there was an indifference to permanence, so long as the function was served; and much of the art was expected to be either consumed or discarded after a celebrative appearance. There is a substantial percentage of intentionally ephemeral folk art—the marriage bowl broken after the ceremony, paper objects burned at funerals, festival breads, carnival figures, graffiti, snowmen; temporary symbolic designs were drawn on the threshold on feast days in India, for example, and were formed of flower petals for religious processions in Italy. Folk-art collections, thus dependent at least in part upon the accidents of survival, must be supplemented by photographic and written documentation in order for a representative view of the whole art to be obtained.

Art to be destroyed

The role of continuous tradition. The element of retention (prolonged survivals of tradition) is considered fundamental in folk art, as it is in folklore. In an isolated situation, the sophisticated ideas that penetrate are generally belated and simplified, and there is a natural trend toward conservatism. Both local and ancient traditions maintain a strong hold. Serviceable forms and familiar motifs are likely to persist, and changes are gradual in comparison to the sudden innovations possible in sophisticated art.

Yet a constant individuality and ingenuity affect the familiar mode, and an art uninhibited by arbitrary aesthetic rules takes many fresh directions. Thus, the fluctuating combination of retained and inventive elements is of significant interest.

CHARACTERISTIC MATERIALS AND TECHNIQUES

The most easily distinguished characteristics of folk art as a whole relate to materials and techniques. Most commonly used were the natural substances that came readily to hand; thus, various materials that have little or no place in sophisticated art, such as straw, may figure importantly in folk art. Sophisticated media, such as oil painting, might be adopted if they could be manipulated, and manufactured products—notably paper, which was cheap and versatile—might be used where available. The unique forms evolved in these sophisticated media illustrate the way in which folk art draws upon the general culture in a limited way, while developing along original lines of its own.

Tools were usually few and often multipurpose: delicate Polish cut-paper designs were often executed with clumsy sheep shears; and in woodwork, chip carving (with ax or hatchet) and notch carving (V-shaped cuts with a knife) were widely used.

Some arts were well within the compass of folk technology; textiles often rival the sophisticated handmade product in workmanship (differences being a matter of styles and themes). In many crafts, however, the folk artists evolved simpler methods of their own. Cut tin, in silhouette shapes or decorated by hand painting or pricking (marking out a design with small punctures), for example, is a common folk medium, whereas full-round bronze sculpture was not likely to be attempted. Again, the French Canadians used wood for "cathedrals" that were carpentered adaptations of their European stone prototypes.

Devices used to overcome technical deficiencies

Large-scale figures often reveal special devices that were invented to overcome technical deficiencies; some are crudely assembled from parts; many maintain a simple overall shape with details merely incised; feet might be represented by pegs inserted into bored holes. In pictorial representation, the difficulties of three-dimensional modelling, while readily solved by some groups, frequently resulted in a preference for outline and flat shapes; for the easier, profile view; and for the evolution of such forms as the silhouette and the shadow picture, made by outlining and filling in the shadow of a head cast onto the wall or paper. The limitations forced a mutation in forms.

Folk art in the urban environment. Folk art is by no means restricted to characteristic regional groups or rural arts. It occurs, for example, among minority groups bent on preserving their ethnic or religious traditions and their typical products. There are various folk manifestations within an urban environment, particularly in connection with the celebrative arts, which have a strong traditional hold; for example, at Christmastime in Warsaw, the people carry about the city models they have made of their cathedral. Covered with salvaged coloured foil, the models incorporate a Nativity scene and are lighted by candles or, more recently, by small bulbs and batteries.

Collective versus individual art. While many folk artists are known by name and many specialized in a particular art form, the skills were mainly available to all (with a distinction between the crafts of men and women), and most of the people were productive. The originality that delights the collector was not emphasized by the people themselves, who were concerned with producing the best examples they could of the desired object decorated with the appropriate and traditional image. Without consideration of the group involved and of the circumstances of folk culture in general, the art can scarcely be interpreted.

CATEGORIES OF FOLK ART

Only a part of folk art falls into the recognized sophisticated categories of visual art, and even that part has its own adaptations.

Architecture. In architecture the focus is naturally on the basic dwelling and on a simple public or religious building. One of the oldest and most remarkable dwelling forms survives in the *trullo* of Puglia, in Italy. A circular dry-stone structure with a tall conical roof, it is often decorated with symbolic designs splashed in white; for multiple rooms, the basic construction is simply repeated. The whitewashed stone architecture of the Greek islands, combining basic cubic forms with a variety of free shapes and inventive projections of balconies, overhangs, and exterior stairways, has been extensively studied and acclaimed by modern architects—as have the wooden churches of eastern Europe, with their delicate, needlelike wooden spires, and the wooden-stave churches of Scandinavia. Other unique forms are the Alpine house, with its steep, wide-eaved roof designed for snow; the cave dwellings of Spain, some with several rooms and a constructed exterior front; the adobe house; and the log cabin. A characteristic design may evolve for such outbuildings as the granary (notably the *hórreos* of Galicia), the dovecote, the straw shepherd's hut, or the barn. In community building, the walled agricultural villages with radial pathways to surrounding fields, the fishing villages which are oriented to a harbour, and the American stockade cluster as well as the village common exemplify the close relationship of folk design to folk activities.

Painting. The idea of a picture to be hung on the wall is by no means universal in folk art. It occurs in Eu-

Street on the Island of Mykonos, Greece, Greek island folk architecture.

Myron Goldfinger New York

The "picture" in folk art

rope, notably as the ex-voto, or votive offering, hung in churches and chapels, and in America, where portraits and local scenes were executed in oil, pastel, or watercolour. More typically, the painted depictions that occur in folk art are incorporated into other objects; for example, the American clock faces bearing local landscapes. A feature of some folk art is the "picture" displayed like a painted one but executed in such nonpaint media as fern, cork, shells, or embroidery. Oil paints and prepared canvasses are sophisticated materials and, though sometimes available, were often replaced by house paint or chalk and by silk, linen, or cotton fabric. Painting on velvet and underglass painting emerged as specific folk types. The amount of decorative painting on a particular object is often very extensive; among German and German-American groups, for example, every inch of a chest, bed, or chair surface might be covered. Walls or beams were commonly decorated with geometric and floral motifs and occasionally with scenes, though the available space did not encourage anything approximating the sophisticated mural. Painting on exterior walls was a feature in some areas, including parts of North Africa and India as well as Europe. Stencil painting, widely used for furniture and walls, illustrates the folk capacity for achieving varied effects within technical limitations.

In America the technique was applied to "theorem painting" (painting on velvet through a stencil, usually done with a dauber or pad and with some attempt at shading).

Miniatures

Sculpture. Some form of figural sculpture and a quantity of incised or relief decoration applied to a variety of objects appear to be almost universal among societies. Work in wood was particularly widespread, though stone, a more difficult material, was also used, especially for gravestones and religious sculpture. Papier-mâché, with its quick and bold effects, was widely adopted both in the East and West for carnival and votive figures and for a multitude of toys. The folk artist was often at his best in making small things, delighting in toys, small-scale representations of daily activities, and such oddities as ships carved inside bottles. Miniature sculptures were often skillfully executed in elaborate groups displaying a cohesive harmony; in Russia, for example, an entire herd of cattle was mounted on a jointed trellis designed to provide a scissorlike movement to the whole. Some figural types were created to be set up in groups, as were the European crèche figures (making up the Nativity or manger scene), toy soldiers, and Chinese miniature wedding processions. The creation of useful objects in an overall sculptured shape, both in pottery and wood, is also typical. In southern Europe or in Mexico, a bottle, flask, or candlestick might take human, fish, or other forms; a Moravian beehive, for example, might be a sculptured head.

The folk print. The wood block (also used for stamping textiles) was the natural folk medium for making prints. Usually simply cut and sometimes crudely coloured or stencilled, they served to illustrate popular subjects, with more interest often in the idea than in the depiction itself. Small prints of various saints were widely produced in Europe. Comic themes were popular, such as the "topsy-turvy world" and "man reversed" (*e.g.,* "the fish catches the man") and stock characters. Block printing was also used to produce games, announcements for travelling shows, and forms for certificates. The English broadsheets and the Mexican *calaveras* (literally "skulls," a category of prints, sometimes made from lead cuts) offer outstanding examples of the cheap printed sheets that combined a verbal message (verses, proverbs, polemics, pious themes) with illustration. The 19th-century trade cards (notice for a shop or service) are sometimes included in folk art, but doubtfully so; they were often machine printed. In fact, it is difficult to segregate the print of truly folk character from the voluminous field of either "popular" or commercial printing.

Other arts. In the folk field, the minor arts can hardly be called minor, for such universal necessities as pottery, textiles, costume, and furniture and more unusual forms such as weather vanes and scarecrows provided the most frequent opportunities for creative expression and often absorbed the aesthetic impetus that, in the sophisticated world, was associated more with the fine arts.

Both pottery and textiles range from the everyday to elaborately decorated forms that are often symbolic or highly pictorial; even common examples are typically ornamented with design in a simple slip (a mixture of clay and water) or a woven band.

Folk costume is justly included in many general works on costume, but it differs significantly from the sophisticated in several respects: in a localism so extreme that even a particular town or valley may have its own prized style and every region is distinctive; in the complete differen-

tiation of the festival costume from ordinary clothing; and in a prolongation of style that is little affected either by changes of fashion or by individual taste. The motifs which are typical of festival costumes, such as the twin, cone-shaped buttons symbolizing fertility in Sardinia, are too deep-rooted in the tradition of the area to be discarded.

Furniture tends toward basic, repeated shapes, which may be left purely functional but are often extensively carved or painted. The Alsatian chair, for instance, has an upright-board back, carved with a pierced, silhouetted, bilateral design; some hundreds of variations of this simple design have been recorded within the area. Certain occupational forms emerged, according to need, such as the milking stool, the cobbler's bench, and the rocking bench, or "mammy settle."

In metalwork, the materials used to produce tools and other essentials were also turned by the craftsmen into such art forms as toleware (painted tin or tinned iron), incised copper or silver, pewter toys, and lead figurines. European wrought-iron grave crosses and shop signs are distinguished by intricate scrollwork and inventive linear depictions. Delicate bone carving is very widespread, appearing on such objects as implements, game pieces (such as chessmen), figures (notably crucifixes), and ornaments. An art peculiar to North America is the whalebone carving (scrimshaw) made by sailors while at sea.

Theatrical arts

The theatrical arts are spectacularly represented by puppetry, ranging from toy theatres, finger puppets, and the ubiquitous Punch and Judy shows to the famous puppet theatres of Sicily and Indonesia. Among the appurtenances of travelling shows and miracle plays, dating from the earlier phase of European folk art, was the hobbyhorse, which had a counterpart in festival performances in India. Musical instruments offer a profusion of types, often preserving ancient features of construction, principles of sound, and decoration: the heavy ratchets and rattles of the Alpine festivals; the shaggy bagpipes of the Abruzzi mountains; fiddles such as the rudimentary *gusle* of Yugoslavia, with its typical horsehead or horseman scroll, and the more complicated Norwegian *Hardangerfele,* with underlying sympathetic strings; and innumerable ornamented flutes, harps, horns, and dulcimers. The simple, painted clay whistle or flute is widespread, often in mimetic bird shape.

Specific folk categories. Any attempt to analyze folk art in terms of the established, sophisticated categories, though revealing in comparison, fails to take into account a substantial bulk of the art. Many characteristic products not subject to sophisticated aesthetic treatment have become specific fields of study and collection because of the ingenuity expended upon them—mangles (laundry beaters), molds, decorated eggs, weather vanes, decoys, powder horns, trade signs, scarecrows, and figureheads, to name a few. There are also significant objects categorized according to function; for example, animal gear represented by the woven harness of donkeys in Spain, carved and painted ox yokes and sheep collars, brass-studded and tasselled headpieces, and ornaments supposedly endowed with protective powers. Other widespread types are decorated vehicles such as gypsy and circus wagons, boats bearing symbolic motifs, and toys and miniatures in countless media.

Freedom of media. While some of the art is executed in a recognized sophisticated medium like wood carving, many other materials, such as hide, horn, straw, bamboo, and palm leaf, are characteristic in certain regions or for certain objects. In fact, there is scarcely an available material that is not utilized somewhere in folk art, from the hickory-nut doll to the commemorative picture made of human hair, and materials are often combined. This free-wheeling employment of any sort of material rivals the fertile adaptations of "found objects" in 20th-century sophisticated art—as many other modern "innovations" have a long-standing precedent in the spontaneous art of the folk. Collage, and assemblage are an old story in this field; embroidered pictures had faces painted in watercolour, and festival figures were made of anything that came to hand. Weather charms in southern Germany were often collages of—among other things—saints' pictures, amulets, and seeds. There is also a great deal of kinetic art: manipulated masks; jointed dolls, figures, and toys; whirligigs (spinning toys); pinwheels spun by wind or candle heat; and balance figures set in motion by a touch. Folk festivals, with their impromptu processions, costumed personages, antics, and props, offer almost a prototype of the 20th-century "happening."

Kinetic art

STYLE

Although the folk artist had his own criteria of function and craftsmanship, design in the theoretical sense was not a part of his training; rather, it was the natural result either of his continued use of established patterns or of instinctive methods of organization. In special instances there was deliberate imitation of well-known works of art, as in the American portraits of George Washington and folk versions of famous Virgins and Buddhas.

Any particular folk art will necessarily share the style of its general cultural area; Chinese folk art is Chinese as well as folk. Thus, analysis of the style and recognition of its folk origin is dependent upon knowledge of the "high art" with which it interacts, as well as of the folk situation that sets it apart. When a folk piece is compared with an adjacent sophisticated one produced at the same time, the differences become apparent, whether in the nature of the object as a whole or in its material, execution, content, or style. Stylistically, the time lag is significant; for example, the Baroque curve survived in simple country churches, and elaborate floral ornament in furniture decoration, long after sophisticated European art had become neoclassical.

Commonly accepted notions of folk style

One of the commonly accepted notions of folk style is that it is naive; it is thought to be childlike and fresh, despite the fact that some of its 19th-century critics condemned its "meaningless repetitions" and its "degenerate" forms. Repetitiveness is to be expected in the production of objects needed by all; but the artists saw only a few neighbouring examples, and to the practiced eye their art reveals many variations. Folk art is often associated with bright colour and an appealing charm, qualities sufficiently present to account for a wide popularity but counterbalanced by the sombreness and seriousness of many pieces, notably in religious art. In fact, few commonly accepted notions of folk style apply to the entire field. Execution may be free or meticulous. Representations of figures may be highly literal (even to the inclusion of actual hair and clothing), almost abstractly simplified, or monstrously exaggerated and distorted, as in, for example, the boldly painted papier-mâché carnival figures of Europe or the fantastic animal figures of the Far East.

The focus on utilitarian production leaves its mark in two opposite ways: often there is a strong decorative orientation, with a wealth of surface ornament lavished on objects that maintain a prescribed shape; on the other hand, certain categories of folk production, such as simple tools, and the work of certain groups are characterized by a functionalism so complete as to seem in tune with modern sophisticated design. Technical limitations and the demand for a quantity of certain necessary objects are conducive to simplification; the reverse may be true of such an object as the bridal bedspread, for which custom dictates extreme elaboration.

The particularly long retention of traditional forms and patterns generally results in increasingly stylized versions of themes; in crewel embroidery, for example, the representation of landscape elements is commonly reduced to a tree and hills, the hills typically shown as three simple, rounded humps; in American portrait painting, the bust or figure is conventionalized in a simple frontal form, repeated over and over again and sometimes painted in advance of a sitting, leaving only the features to be filled in. More important, perhaps, is the fact that the adoption of materials not used in sophisticated art, the forcing of a limited technology toward artistic expression, and the adaptation of rather remotely perceived sophisticated ideas to the folk artists' concept of the realities of life result in some highly original stylistic solutions.

CONTENT AND MOTIFS

Whereas sophisticated art often reaches out for the esoteric and the unusual, the content of folk art is closely related to immediate human concerns. The major events of life were universally celebrated on the folk level in ways that demanded of art special costumes, implements, vessels, and auspicious gifts. For the newborn there might be amulets and decorated birth certificates. The period of courtship occasioned a love token, often a beautifully carved feminine implement such as a shuttle or needle case; traditional in England was a double spoon symbolizing union and plenty, whereas in Czechoslovakia it was often a painted egg or carved stick. In many regions elaborate wedding chests were carved or painted for the bride. The bridal bedspread or bed curtain, like the wedding costume, was ornate and highly symbolic, with such motifs as Adam and Eve, the tree of life, and mating birds considered appropriate. Both weddings and funerals required processional equipment, standards, and special vehicles. In some places there were gifts for the dead, which in China took the form of paper models burned at funerals. There were memorials such as grave sculpture, pictures, and documents.

Specific memorial motifs crystallized in two American forms: the "mourning picture," executed in embroidery or watercolour, often depicting grieving figures draped around a tombstone under weeping willows, and the gravestone carved with a winged death's-head or, later, with the urn-and-willow motif.

Religious art. The prevailing religion puts its stamp on the consciousness of every group, providing common elements in areas that share the same religion, even though the groups are not in contact. Catholicism in the West (and, similarly, Buddhism in the East) provided rich visual conceptions and evocative images that spilled over into folk art. Crucifixes, Virgins, and saints were required as images for village churches and wayside shrines; they were set up over gateways and tombs, in arches, and in homes and were used as motifs on countless objects, where they were often freely combined with secular decoration. Religious observance demanded many objects decorated with Christian symbols—baptismal scoops, altar cloths, pilgrimage bottles, lavabos (holy-water vessels). There is even a special category of "nuns' work," including small devotional objects, many in collage, as well as vestments and church textiles. A particular German sculptural type is the *Palmesel*, a half-size figure of Christ on the donkey, which is drawn through the streets on its wheeled base on Palm Sunday.

Influence of Catholicism

An outstanding category of Catholic folk art is the crèche, made up of figurines displayed at Christmas in homes or churches to reenact the birth of Christ. The main characters of the event (holy family, Magi, shepherds, and angels) were supplemented by hundreds of lively figures drawn from peasant or village life and shown pursuing their daily activities or bearing gifts to the Christ child similar to those enumerated in folk carols.

The Protestant and Jewish faiths made fewer demands on the visual arts, but the popularity of Biblical themes is apparent. A favorite motif for the American weather vane was the angel Gabriel blowing his trumpet, often executed in a style that survives from the puffing zephyrs of classical art. The noteworthy Jewish folk art of Poland was largely lost during World War II, though records of the unique folk synagogues have been preserved by the Institute of Polish Architecture. The Jewish folk-art collection in the Musée Alsacien, Strasbourg, France, includes such specific religious objects as pointers (carved sticks used to guide the reading of sacred texts) and candelabra.

Since antiquity, some form of votive art has occurred in connection with religion. In India, outdoor shrines may be surrounded by a veritable crowd of papier-mâché figures set on the ground as offerings. Catholic churches and chapels throughout the world are hung with countless small ex-votos, usually cutouts of stamped tin or silver in the shape of an afflicted part of the body—an arm, a leg, or an eye—or of the heart or other symbol. In Canadian Jesuit missions, ex-votos were even made of wampum. In Seville small ivory carvings of religious figures were left in the cathedral by soldiers going to war. Clay plaques made from molds, common in the Mediterranean area, show an inheritance from Greek times, when small clay molds of the head of Athena were stamped out in quantity as votive objects. The most significant art, however, occurs in the painted ex-voto, which provides a major type and some of the best examples of folk painting. In sophisticated art, paintings of standard religious themes were often donated to churches in fulfillment of a vow. In folk art, this votive urge found expression in small narrative paintings (only occasionally large, as in Mexico) depicting an accident, illness, or other disaster from which the victim was saved by the intervention of a saint or the Madonna.

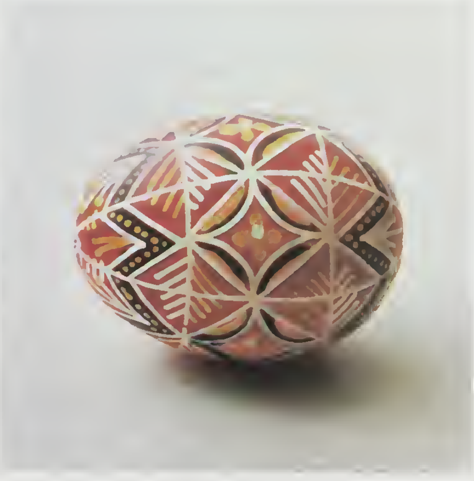
The recognized religion, however, is only a part of folk belief, which is impregnated with concepts from earlier times. The decorated Easter egg, for example, is an evolution of the egg as an ancient symbol of renewed life, and the fat, laughing figure of the Japanese Hotei (god of luck) is both a deity and a ubiquitous folk charm. There are many survivals from local pagan cults, particularly of motifs associated with life, fertility, and protection; in Calabria an animal stake may be carved with the head of the blank-eyed mother-goddess, expected to protect the tethered beast, and similar elemental forms were preserved in Czechoslovakia. Lying at the root of human experience, such themes were never completely abandoned by the folk and may appear in curious juxtaposition with Christian



Decorated Easter egg from Czechoslovakia, 20th century.

themes or secular uses: a Sardinian clay bowl, for example, contains a modelled wedding group with the priest standing before an altar on which a small, nude hermaphroditic deity is seated, and the Christian loaves of bread appear along with pagan phallic and fertility symbols.

Ancient pagan seasonal celebrations

Festival art. A major folk category is festival art, which owes its genesis and much of its content to ancient seasonal celebrations. Since antiquity, the solar manifestations of the summer and winter solstices and the vernal and autumnal equinoxes have been bound up with the idea of sowing and reaping, death and rebirth, year's end and year's opening; at such times it was traditionally believed that supernatural forces were in control and should be propitiated. Re-enactment of the roles of malign spirits called for the production of grotesque masks and demonic costumes and also of clamorous noisemakers (bells, horns, rattles, and the like) to drive them away. Harvest figures invoked or celebrated a good crop yield. Special foods in symbolic shapes were prepared and consumed. Varying according to the culture, many other appurtenances were created—decorated trees and poles, lanterns, banners, processional vehicles, sculptured figures and dolls, household and shrine adornments—all bearing their motifs of life symbolism.

While the magical significance of the primordial festivals may have been largely forgotten and the events reduced to horseplay and merrymaking, the customs and the art objects associated with them persisted. In Europe, masqueraders continued to impersonate such "characters" as death, the devil, the goat, the old man, and the mischief-maker; their masks were often makeshift and ephemeral, but many carved of wood and decorated with other materials are preserved and highly prized. Such personifications were also painted on banners or created by assemblage and carried about, as were the Mexican skeletal death figures.

Oriental festivals often featured plant and animal motifs. In China the dragon of the New Year was a great paper creation made to undulate by the dancing steps of the bearers underneath. In the Japanese boys' festival, painted paper carp were flown from poles as symbols of strength and virility. In Indonesia, towering decorative constructions of vegetables and fruits were borne about to celebrate the harvest.

The assimilation of ancient seasonal celebrations—the winter solstice and the Roman Saturnalia with Christmas, for example—has been extensively studied in European folklore. In folk art, it occasioned an intermingling of pagan and Christian elements, enriched by many inventions created in an exuberant festival atmosphere and readily incorporating local and current themes. The celebrative instinct found expression also in many purely local festivals commemorating a local saint, historical event, or an episode in folk life, such as the setting out of the fishing boats or the onset of rains. In Japan alone, there were hundreds of such festivals.

Other sources of folk motifs. The traditional survivals that play so significant a part in folk art stem from other sources as well. Certain motifs diffused from the earliest cultures provided a repertory of stylized symbols to meet decorative demands; for example, the rosette (a disk divided variously into petallike segments), the rayed disk and the swastika (both associated with sun symbolism), the tree of life, the chimera and other fantastic beasts, and such human-animal combinations as the siren or mermaid. The extent to which such motifs retain their meaning or may become simply an appropriate decoration for a certain type of object (as the mermaid is for boats) is problematical, but there is undoubtedly a high symbolic content in the art.

Use of medieval and Renaissance themes

Some aspects of classical mythology fed into folk art, partly by way of later European sophisticated art, and many medieval themes remained popular; the Saracen of the Crusades is a figure that still appears as a Sicilian puppet and as a revolving target in tilting games. Early Renaissance conceptions of paradise and landscapes with stylized trees and towered towns oddly recur in 19th-century folk painting, sometimes imparting an esoteric flavour to a local scene. In fact, the body of tradition retained in folk art may be seen as growing or shifting from one century or one place to another. A folk version of the horse-and-rider motif, in typical profile view, served with only a slight change of uniform for both the Napoleonic and the American Revolutionary soldier.

Although themes may fall into disuse, they do not become obsolete so readily as in sophisticated art. Yet, folk art is not merely a repository for tradition; new themes constantly evolve from old ones or out of new circumstances. In the wine-producing area around Alsace, Bacchus astride a barrel became the common motif for carved bungs (the stopper of a cask), thus utilizing the classical Bacchus for a specific local commodity. In America, the Indian was widely adopted for weather vanes, trade figures, and other objects. Similar use was made of the personification of Liberty and the emblematic eagle.

Sheet-iron weather vane, unknown artist, *c.* 1810. In the Shelburne Museum, Inc., Vermont. Height 1.3 m.

Geometric and plant and animal motifs

All decorative design draws heavily on geometric and plant and animal motifs. In the folk use of this material there is often such concentration on one or two motifs that they become strongly identified with the regional style, as the tulip is in Pennsylvania German art; there is also a tendency to attach a particular motif to a particular object, for which it is used repeatedly. The prevalence of animal themes reflects the importance of animals in folk life.

Aside from their frequent appearance as realistic depictions, miniatures, and design elements, some animals also have strong symbolic aspects: the snake, the horse, and the cock, for example, occur with varying significance in many parts of the world.

Representational and narrative art other than the religious is often devoted to local subjects: the family portrait, the individual farm or church, or a typical activity. In Switzerland a favourite theme was the *Alpengang*, depicting the transferral of the cattle to high pastures in the spring. Folk artists also drew upon legend, popular romance, history, and the more famous literary and visual art themes that reached them from the sophisticated world. In Sicily the deeds of Roland (Orlando), derived from the poetic accounts by Torquato Tasso and Ludovico Ariosto, were repeatedly painted and enacted in puppet shows. From history, the patriot Giuseppe Garibaldi was as popular in Italian folk art as George Washington was in American; and the Prince of Wales was a favourite figure for pub signs in England.

Account must also be taken of the folk capacity for satire.

The anticlerical humour of Italy has a folk manifestation in caricatures of impious monks and nuns. The Russians evolved stock figurines of the snobbish officer, the vain woman, the greedy merchant, the pretty girl riding on a rooster. The early prints of London and Paris had their lampoons, and Mexico had its effigies of personages who did not meet popular approval. Out of the slow exolutions typical of a strongly traditional art, there emerges an astute view of the human situation.

MAJOR FOLK REGIONS

The major recognized folk regions in most cases have been prolific in such crafts as textiles, pottery, and carving and in the production of implements and utensils; they also often have localized costumes. This common art output forms a broad basis underlying the more distinctive arts peculiar to particular areas. The material is so voluminous that most attempts at general survey are admittedly samplings.

General summaries are commonly organized by nation, a convenient expedient, because major collections are centred in great national museums and because folk art is often studied and promoted as part of the national heritage. However, the national summary divides some groups that are homogeneous, such as the Basque region in Spain and France; and it combines, under Italy, for example, such diverse arts as the Alpine and Sicilian.

Any effort to group regions for comparative study will most logically be based on such factors as the traditional retained sources, the prevailing religion, the nature of the related sophisticated culture, and the environmental conditions that affect materials and activities.

Western. *Mediterranean.* Viewed in terms of these four factors, the European folk arts of the Mediterranean area obviously have much in common. First, there was a direct transmission from ancient Near Eastern and Greek civilization, accentuated by Greek colonization in the West and followed by Roman domination. These sources, plus the local cults that occurred everywhere, may be traced even in recent art in the continuance of a rich pottery tradition from Greek times onward and in the preservation of many motifs. Second, the religion, chiefly Roman Catholic or Greek Orthodox, demanded extensive imagery. Third, in the sophisticated cultures throughout the historical period, art of all kinds was a major activity, developing high skills that penetrated to some extent even to the more isolated folk. Finally, contact was facilitated by active trade along an extensive coastline, and varied materials were available; yet the area industrialized very slowly, so that the folk arts could continue to thrive in some localities even to the present.

Outstanding quantity and variety of Mediterranean arts

Thus, it is not surprising that the arts of this region are outstanding in quantity and variety. The level of skill is apparent, sometimes in bold and facile styles, sometimes in meticulous craftsmanship. Many folk artists were capable of expert full-round sculpture, realistic painting, fine metalwork, and other difficult techniques. The motifs are varied and freely intermingled.

Among the long-surviving regional arts are those of Epirus in Greece, where an important folk centre has been established at Metsovon; the islands—the Aegean with its stone architecture, Sicily with its spectacular carved and painted carts, puppets, and pottery, and Sardinia, noted for gold ornaments, textiles, and costumes still in use; and Puglia, Calabria, and the Abruzzi region in Italy, the latter having fine lace, silver filigree (openwork), and weaving.

Southern France is affiliated with this area, as is evidenced by the style of the fine ex-votos and Nativity figures of Provence. So is the Iberian Peninsula, though in that region there are also special factors. The Moorish influence was felt particularly in Andalusia—as in the use of ivory as a material and in the arabesque tracery (ornate, interlaced openwork) of the ironwork—and the Atlantic coastline provided other connections. The Portuguese use of cork was distinctive. Galicia and the Basque region, each with a population of distinct linguistic background, developed in prolonged isolation, the results of which are clearly visible in their exceptional arts: the architecture presents unique features, and the Basques are unusual in their lack of pottery, though they developed remarkable dance costumes. The difficulty of communications preserved a strong folk character not only in Galicia and the Basque region but throughout the peninsula. The painted and glazed tiles (*azulejos*), the textiles (notable in Salamanca), and carved furniture are among the products notably Iberian in character. Traditional survivals were strong in the northeast, with much religious art, including prints, centred in Catalonia.

Slavic area. Another possible grouping is the Slavic area in eastern Europe and Russia. There the influences from the ancient Near East and Greece penetrated less far in early times but were transmitted (and transmuted) by way of the Byzantine Empire and the Eastern Church. Much folk art in the area was strongly affected by the Byzantine style.

Among the transmitted elements were the themes and styles associated with icons, which were commonly hung—at wells, for example—until the mid-18th century, when their production was discouraged in Russia and thus dwindled. Two centuries of Mongol rule introduced other traditions stemming from the East and marked by the so-called animal style. Finally, in modern times, these countries have mostly had Communist governments, whose policy includes promotion of the folk arts, organization of artists into cooperatives, and even the introduction of crafts from one area into another. Although this has been a stimulus to the study of folk art, it tends to blur the distinction between the strictly folk and the revived or commercialized product. Even earlier, Russian folk art was subject to extraneous influences in a way not typical elsewhere: in the 17th century, craftsmen were requisitioned from many parts of Russia to supply products for the national economy or to work on palaces, and they were also assembled around monasteries for prescribed output.

The Russian products probably best known elsewhere are toys—intricate constructions of wood or vivid earthenware miniatures. Some of the Vyatka toys are thought to be survivals of idols made for homes, representing the innumerable local deities that preceded Christianity. Other notable arts include ceramic tiles, wooden and ceramic figurines, and bone carving in the Siberian tradition.

Eastern European woodwork

In eastern Europe, where national boundaries have been particularly confused and the population comprises various minorities, studies of the art may follow ethnic lines. The geography provides a number of distinct regions, which are as varied as coastal Dalmatia, Transdanubia, and the isolated Tatras mountains. With a heavily forested landscape, the work in wood was outstanding. It appeared in church architecture, architectural sculpture, vessels and implements, and in such special forms as the sculptured grave-post; even a corn bin might be covered with rosettes. The area was rich in festival arts, with a strong retention from pre-Christian traditions and magic rites. In Czechoslovakia there were special wedding effigies and candlesticks. Among many ancient motifs, such as vase-and-tree, sun, and heart, the cock appeared as a protective symbol that might be set on roof ridges or carved on cheese molds. Some of the art is strikingly primitive.

One of the complications arising in the study of eastern European arts is the fact that the countries involved are culturally borderline, having an affinity with Catholic

Europe in the West (exemplified by the ex-votos in the brilliant Czechoslovakian glass painting) and with the Byzantine Empire in the East. The arts bracketed as Polish, including some of the finest decorative art in paper, once extended far to the east and yet are northern European.

Northern Europe. The situation in northern Europe was very different from that in the south, and not merely in climate. The tradition involved a different mythology, and the society lacked the sophisticated centres that had crystallized early in Greece and Italy. The Roman influences that reached northern Europe had far to travel; consequently, the transmitted motifs were fewer, and emphasis might be placed on technical execution rather than on variety. This can be seen in the prevalent and superb use of two motifs, the acanthus and the vine-and-tendril. It can also be seen in the animal style from the East, which penetrated and persisted, for example, in some fine architectural carving, with the tendency typical of this style toward flat and pierced rather than full-round rendering. Finally, although religious art was by no means lacking, the Reformation, which in itself was a popular movement, curbed the use of extensive Catholic imagery as well as the demand for religious objects.

The festival arts drew heavily on northern pagan themes, and the impulse that gave rise to pre-Lenten carnivals of the south was likely to find expression rather in municipal and occupational processions with comic giant figures drawn through the streets.

Some parts of the far north demonstrate that density of population is a factor in folk art; where farms are many miles apart with few opportunities for community contact, the art forms may tend to be few or even nonexistent. Even so, there may be one or two special crafts, such as the bone and horn carving of Lapland. Also, where materials are scarce, as in Iceland, variety of product depends on imports likely to be allocated to the sophisticated, not the folk. In more densely populated France, Germany, and The Netherlands, on the other hand, it is clear that peasant arts existed everywhere in the earlier periods but that the early establishment of trade routes and urban centres pushed the folk arts into special categories or into the peripheral areas.

Among the Scandinavian regions, Norway is noted for the rose painting of Hallingdal and Telemark Fylke, the needlework of Hardanger, and the pictorial weaving of Gudbrandsdalen. Sweden, among varied arts, had a unique type of built-in furniture and wall hangings that were either painted or woven with biblical and Icelandic motifs. Finland had a specific linear ornament called "dark drawing," made by bending a strip of wood until the ends meet, and metal ornaments of prehistoric origin in Karelia. Distinctive folk-art regions in Denmark include the Hedebo (now Hedeboryde) area, with its linen embroidery; the Fyn archipelago, with its colourful floral painting; and Jutland and Slesvig, with notable cabinetmaking. In the Baltic area there were many survivals of ancient motifs (swastikas, rayed disks, snakes, horse heads) used on varied products, including the remarkable crosses and roofed poles, often with symbolic wrought-iron finials (crowning ornaments).

"Justitia," Gudbrandsdal tapestry, probably late 17th century. In the Norsk Folkemuseum, Oslo. 145 × 178 cm.

Central Europe. In the heart of Europe, two areas demonstrate special factors involved in the formation of folk culture: the Rhineland, where wine production provided a number of special objects and motifs; and the Alpine regions, which, though extending into several countries, share a pattern of living dictated by the mountain territory. The latter region, which includes several well-defined areas—such as the Appenzell in Switzerland, the Tirol in Austria, and the Alto Adige in the south Tirol, now a part of Italy—is rich in festival arts, ceremonial foods, and implements associated with dairying (even musical cowbells).

Arts of the Alpine region

In France, The Netherlands, and Germany, the proximity of folk groups to sophisticated culture made its mark in the variety of products, high skills, and lavish decoration of such objects as furniture. Invention was devoted to new figural types, such as the hod carrier common to lower Germany and Austria; and events such as the Napoleonic Wars made a rather quick impact, as with the soldier motif and the appearance of handwritten and ornamented documents relating to military service. The mechanical genius that made the Germanic peoples leaders in the field of sophisticated automata found folk expression in innumerable animated toys, clocks, chimes, figures, and other gadgets. While the folk art associated with Paris itself is not to be ignored, the more easily analyzed French groups are outlying, as in Brittany, with its many-figured outdoor calvaries (representations of the crucifixion) and other enduring forms.

Britain and Ireland. The tendency to separate British from other European folk arts is an oversimplification, for a number of forms are shared with northern Europe; for example, the famous horse brasses (circular harness ornaments often retaining ancient protective motifs), giant processional figures such as the Salisbury dragon, and the May tree, a celebrative decoration in pole form. England is a small country that industrialized rapidly, a factor that tends to shorten the folk-art period. Some arts that required expanding technical skills, however, could develop as folk forms: for example, the printed arts (such as the broadside, or sheet printed on one or on both sides and folded) and the hand-propelled roundabout (later the mechanized carousel), which became increasingly elaborate. Tunbridge woodwork, of glued coloured strips, is merely one example of local invention. Among the well-known categories of folk art are the inn signs (both hanging and "effigy" signs), wroughtiron work, and tombstones. Hebridean textiles and Highland plaids and sporrans (the pouch worn in front of the kilt) are also familiar products. Both Scotland and Ireland have interesting grave crosses bearing ancient symbols. Ireland, however, serves as a reminder that the creative urge of a folk group may not focus primarily on the visual arts; Irish folk art does not compare with the contribution to oral lore in that area. (The same may be said of the black folk minority in the United States, whose musical contribution was spectacular but whose visual art traditions were largely cut off.)

North America. The colonization of the Americas in the 17th and 18th centuries, stemming largely from Europe at a time when European folk art was flourishing, resulted in a second general area of major folk-art development. This art can be divided into that of the United States (loosely called American folk art); Canadian folk art, which has much in common with that of the United States, with its scrimshaw, ship carving, and western pioneer art, but which also has products of its own (for example, French-Canadian wood carving in Quebec); and Latin-American folk art, which has quite a different character.

For the first century and a half, the art of the eastern seaboard of the United States may be described as predominantly folk. Although there were European imports and works produced by sophisticated American artists, they were generally a pallid reflection of the art then developing in Europe, and they made little impact on a people bent on making a home in a new world. The so-called Yankee ingenuity produced a wealth of material, sometimes reminiscent of European prototypes but often new. There were, for example, dozens of handmade lighting devices and many specialized contrivances such as the trammel, for raising and lowering pots in the fireplace, and the corn planter. Fresh decorative styles, special forms, and new motifs contributed to an art that, either in evolution or invention, was typically American.

American folk painting

American folk painting is outstanding. Although there was once a tendency to view as sophisticated the artists who closely followed European styles and as folk those who worked in the rapidly emerging American manner, many of the latter have become individually known creators of a valuable body of work and have taken their place in the history of American art, some no longer viewed as belonging in the folk category. The more typical folk product comprised thousands of portraits and scenes by anonymous or local craftsman-artists or itinerant painters, who provided a vivid, if often crude, extensive record of America's ancestors and their surroundings.

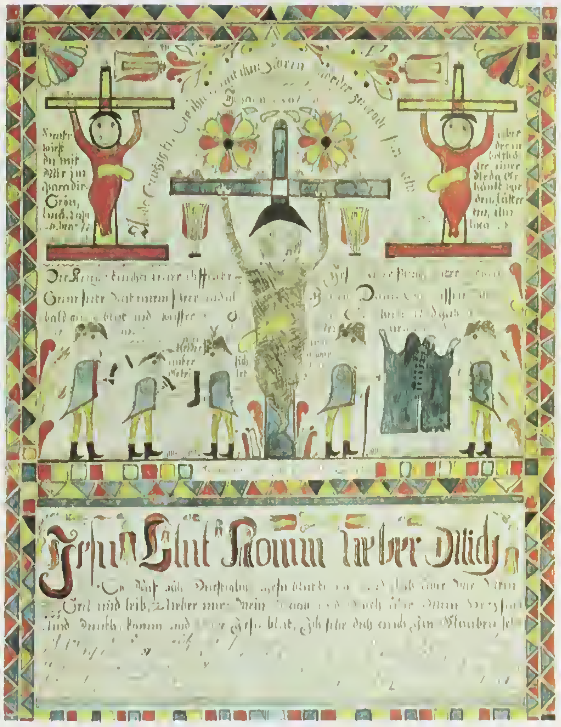
As America advanced, a pattern of regional differentiation appeared, just as in Europe. In general, geographical isolation was overcome rather quickly, one exception being the sparse settlements of the Appalachian Mountains, where Scots-Irish descendants maintained a handicraft tradition. People of varying origins, however, had brought to the "melting pot" of America their different art traditions. While they were often content with preserving a few objects and customs, some groups chose to maintain a separate identity, set apart by religion or national origin, and among them some fresh regional arts developed. The strict religious beliefs of the Shakers in New England and New York state, with their emphasis on simplicity, gave rise to clean, functional lines in furniture and architecture and to some psychologically interesting "spirit drawings" executed under the influence of religious visions. The Pennsylvania Germans (popularly called Dutch) not only had a distinctive religion but clung tenaciously to the language and traditions of their native Pfalz (Palatinate, now in the state of Rhineland-Pfalz and in Bavaria), which in art included such crafts as fine painted furniture and such motifs as the tulip, heart, and vine. Thriving in the flourishing countryside of their new home, they produced a notable body of art: fraktur (embellished documents), painted wedding chests, decorated ceramics (including elaborate pieces created for special occasions), unique barns with exterior painted symbols ("hex signs"), pictorial embroidery, weaving, and other forms.

Arts of the American west

The American settlers who moved westward were again thrust into a folk situation comparable to that of their forebears, and a pioneer art developed. Saddlery was one of its important crafts; the covered wagon was its distinctive vehicle; and the board structures of mining towns and the sod houses of the plains were solutions to the problem of immediate housing. The flatboat and keelboat of the Mississippi River arose from specific navigational requirements.

The southwest, including part of California, is an area apart, producing art distinct from what is often called "western Americana." There the architecture was influenced by the Spanish mission and adobe styles, and a Catholic religious art was encouraged among the natives, resulting in the carved or painted imagery of saints (*bultos* and *santos*) with a strong native flavour overlying the Spanish derivation. These arts are more allied with the Latin American (as may be seen in the Museum of International Folk Art in Santa Fe).

Latin America. The different character of Latin-American folk art may be ascribed in part to the modification of a primitive culture resulting from contact with an advanced one. The settlers on the eastern seaboard of North America moved in on a primitive Indian population whose arts were relatively limited and who were rapidly pushed back or disoriented; the folk art of that area was thus essentially the product of the white settlers. In Latin America, however, where there were some highly developed pre-Columbian cultures as well as tribal arts, intermingling was freer; this was partly because the missionary program—which included the teaching of crafts and Catholic symbols to the native population and the use of native craftsmen for church construction and for the production of religious objects—accepted an infusion of native techniques and styles. Thus, Indian crafts and motifs had a better chance of survival, and a greater degree of syncretism could occur. Furthermore, the colonizers, predominantly Spanish and Portuguese, brought with them the wealth of Mediterranean tradition and the varied imagery and forms of their home regions.



"The Crucifixion," fraktur by unknown artist, watercolour on paper, 1847. In the Abby Aldrich Rockefeller Folk Art Collection, Williamsburg, Virginia. 28 × 37 cm.

Explosion of folk art in Mexico

Under circumstances as favourable as these, a virtual explosion of folk art can occur, as it did, notably, in Mexico. Because Mexico seems to have a peculiar receptivity to art impulses regardless of source, the area is distinguished by a folk imagination that can create a towering, multifigured, ceramic candlestick, elaborate figures and models of straw, and fantastic fireworks. Craft motifs are handled with great spontaneity, and the festival arts are remarkable, with such original creations as the Judas figures, the skeletal musicians associated with the Day of the Dead (*dia de los difuntos*), and the skulls (*calaveras*) that appear both as confections and as a theme in popular prints. The religious arts are also outstanding, with many ex-voto paintings (*retablos*) and Nativity figures in varied materials. Art that combines features of the Mediterranean and native Indian traditions occurs also in other Latin-American countries, as in the Portuguese-oriented areas of Brazil and in Argentina, which developed some arts related to the life of the cowboy of the pampas (gaucho). In some regions of Latin America, however, the indigenous Indian culture long remained unaffected and little influenced by the European colonies.

In the Caribbean and coastal areas there is evidence of African–Indian–European interaction: saints are painted with African physiognomy, and African decorative motifs

Day of the Dead toys from Oaxaca, Mexico, pottery and paper, *c.* 1960. In the collection of the Girard Foundation, Santa Fe, New Mexico. Height of largest figure 26.5 cm.

By courtesy of the Girard Foundation, Santa Fe, New Mexico

appear on crosses, votive sculptures (the *milagre* of northeastern Brazil, for example), and such objects as laundry beaters and peanut pounders in Surinam.

Other regions. During the 16th–19th centuries, European exploration, trade, and culture expanded into many parts of the world. Colonization elsewhere, however, was not so conducive to folk evolution as in the Americas, where many settlers emigrated early, bearing folk traditions with them and expecting to make a life with their own skills. Because in many places the Europeans maintained a sophisticated enclave closely tied to the homeland, the native arts were preserved intact, inhibited, or exploited. This was fairly typical in Africa and the primitive Pacific areas, where settled colonization took hold only in the late 19th century. In South Africa, where it occurred earlier, only the Dutch (who built farmhouses of Dutch character) tended even to take their families with them.

Non-Western. In many parts of the world there have been tribal arts, some of which have nonprimitive aspects. These are sometimes bracketed with the primitive in a general category of ethnic art and are sometimes considered as folk art. But although they may have folklike crafts and links with the outside world, they differ from true folk cultures in that they constitute homogeneous societies with traditions that are specifically ethnic rather than shared with a broad area of sophisticated culture. Such tribal folk art occurs in the Saharan Berber and Siberian areas, among the Ainu people of Japan, and in various parts of Asia.

The Eastern art recognized as truly folk has been studied, as in the West, chiefly in the areas where it exists as the local or provincial art within a great culture. The Oriental traditions were often relatively uninterrupted, and effects from industrialization were late; while all folk dating is problematical and much of the art has perished, it is likely that some folk art in the East has a history extending back to ancient times. In Japan, however, it is usually understood as beginning in the Edo period (17th century). Interest in folk art is particularly strong in India and Japan, where there are art scholars familiar with the Western folk concept but dedicated to the preservation of their Eastern traditions. Indian folk art was discovered in an emotional climate reminiscent of the European discovery of the folk soul; Ananda Coomaraswamy, a leader in the movement, called folk art the "main road," as distinguished from the sophisticated "bypaths." Both in India and Japan, there were sophisticated artists who deliberately identified themselves as "folk."

India and Pakistan. In India, where all of the crafts are distinguished by variety, skill, and a strong component of strictly Indian tradition, the folk distinction is not always clear-cut. It is most apparent in such objects as toys (for example, the mother-and-child figure probably related to fertility concepts), masks, works in papier-mâché (votive and animal figures, for example, and dancing dolls balanced on wire), the symbolic motifs painted on the houses of the poor, and other works of art related to local custom or primitive belief. Particularly in southern India, small religious and other sculptures were created in quantity in an unmistakably folk manner; there are also some distinctive tribal arts, notably those of Assam. Pakistan has some highly regional arts: for example, the fine house carving and the ceremonial fans of Swāt, the silver ornaments of Gilgit, and the tombstones and matrimonial objects produced in the arid regions of Baluchistan.

Pakistani regional arts

Japan. Pottery and toys are probably the most widespread kinds of Japanese folk art; but there are also innumerable typical objects—lanterns, fans, umbrellas, nested boxes, and kites—exhibiting skillful use of bamboo and paper, as well as wood, lacquer, and other materials. There are thousands of wayside images, as well as sculptures for shrines and graves, in a folk style characterized by shallow carving on a simple, coarse-stone shape. An outstanding type of folk painting flourished in the Ōtsu region from the 17th to the 19th century. Clearly distinct from the sophisticated ukiyo-e painting, it was executed by farmers and artisans and depicted folk as well as Buddhist deities, popular animal motifs such as the cock-and-hen, and popular characters and genre scenes, often satirical. There are also votive pictures, some portraying the horse and traceable to the ancient horse sacrifice. One of the late-surviving folk regions in modern Japan is on Sado island, where small cylindrical stone images are thrown into the sea to invoke pregnancy.

China. Chinese folk art must have been as extensive as any in the world, as evidenced by the descriptions of Western travellers and the souvenirs they collected and by various cultural and craft studies; but the problem of collating and analyzing the material as a folk category is forbidding. Every Chinese region has its own styles, and the entire art output is enormous. The art associated with weddings, funerals, and festivals is extravagant, even among the poor. In the country where paper was invented in antiquity, papermaking is a common skill, and the art of paper cutting is learned from childhood. Paper is used for the banner-like shop signs that give a special character

to Chinese streets and for many complicated models and festival objects.

Indonesia. In its effect on folk culture, the spread of Buddhism in the Far East has some parallels with the spread of Christianity in the West. In Indonesia, for example, where Buddhism penetrated an area whose local traditions were strong enough to survive and intermingle with the new concepts, there is much temple art of a folk character. Among the abundant ephemeral folk arts of Bali are the vegetal offerings and the beautifully stylized symbolic objects woven of palm leaf. Indonesian shadow puppets and printed textiles are world famous. (Ma.Ha.)

BIBLIOGRAPHY

Folklore: A. AARNE, *The Types of the Folktale,* 2nd rev., trans. and enl. by S. THOMPSON (1961), the standard index and reference work for the most widely distributed European folk narratives; F.J. CHILD (ed.), *The English and Scottish Popular Ballads,* 5 vol. (1882–98), the classic assemblage of 305 ballad types, with variant texts and learned headnotes; W.A. CLOUSTON, *Popular Tales and Fictions,* 2 vol. (1887), an early discussion of the wandering and migrations of folktales between India and Europe; M.R. COX, *Cinderella* (1893), the first comparative study of an international folktale, bringing together 345 variants, and contributing to the thesis of diffusion rather than independent invention of complex tales; L. DEGH, *Folktales and Society* (1969), a depth field study of storytelling behaviour in a Hungarian peasant community, with biographical portraits of leading folk narrators; R.M. DORSON, *American Folklore* (1959), an historical presentation of various folk traditions in the U.S., *The British Folklorists: A History,* and (ed.), *Peasant Customs and Savage Myths: Selections from the British Folklorists,* 2 vol. (both 1968), a history of the concept of folklore as it emerged in England with the 16th-century interest in antiquities and came to fruition among Victorian private scholars in the late 19th century—the volumes of selections present illustrative writings of the folklorists discussed in the history, and "Folktales of the World" (1963–), a series of authoritative volumes each of which is prepared by an eminent folktale scholar from the country represented; A.B. FRIEDMAN, *The Ballad Revival* (1961), interest in the ballad in England by antiquaries, poets, and the public treated in terms of literary history; JACOB GRIMM, *Teutonic Mythology,* trans. by J.S. STALLYBRASS, 4 vol. (1883–88), the encyclopaedic and influential work in which Grimm expounded his theory of the degeneration of an ancient high pantheon of Germanic deities into the extant fairy tales and witch beliefs of the contemporary peasantry; F.R.S. RAGLAN, *The Hero: A Study in Tradition, Myth, and Drama* (1956), a highly controversial explanation of all mythic narratives as following a uniform pattern derived from ancient sacrificial fertility rituals; Y.M. SOKOLOV, *Russian Folklore,* trans. by C.R. SMITH, (1950), a history of Russian folklore research given from the Soviet viewpoint regarding folklore as an expression of the class struggle; S. THOMPSON, *Motif-Index of Folk-Literature,* rev. ed., 6 vol. (1955–58), the major reference work in comparative folklore; J. VANSINA, *Oral Tradition* (1961), presentation of an historical methodology for the African historian enabling him to use oral historical chronicles and genealogies as legitimate source materials; D.K. WILGUS, *Anglo-American Folksong Scholarship Since 1898* (1959), a judicious appraisal of the recent schools of interpretation in ballad and folk-song studies.

Folk art in general: MAMIE HARMON, GIUSEPPE COCCHIARA, and ALESSANDRO MARABOTTINI MARABOTTI, "Folk Art," in the *Encyclopedia of World Art,* vol. 5, col. 452–483 (1961), present a broad, book-length theoretical survey focussed on visual art. A comprehensive work focussed on literature is MARIA LEACH (ed.), *Funk and Wagnalls Standard Dictionary of Folklore, Mythology and Legend* (1949). BRUNO NETTL, *Folk and Traditional Music of the Western Continents* (1956), offers much general theory in the course of treating his specific subject.

Folk literature: The best general treatment of the borderline between folk literature and sophisticated literature is H.M. and N. CHADWICK, *The Growth of Literature,* 3 vol. (1932–40). S. THOMPSON, *The Folktale* (1946), gives an introduction and extensive bibliography for the field of oral narrative literature. For myths of all parts of the world, see *Mythology of all Races,* 13 vol. (1916–32), valuable information, though some of the bibliographies are out of date. *The Journal of Folktale Studies* (3/yr.), and *FF Communications* (irreg.), are of primary importance. They include articles in English, French, and German. *FF Communications* is undoubtedly the leading series for all aspects of folklore. A good recent series of folktale collections in English is "Folktales of the World" ed. by R.M. DORSON. Important also is the much larger series in German, "Märchen der Weltliteratur." For the folktales of the ancient world good introductions are W.M.E. PETRIE (ed.), *Egyptian Tales Translated from the Papyri,* 2 vol. (1899); and S.N. KRAMER, *Sumerian Mythology: A Study of Spiritual and Literary Achievement in the 3d Millennium B.C.,* rev. ed. (1961). The standard Renaissance collection is *The Pentamerone of Giambattista Basile,* ed. and trans. from the Italian of BENEDETTO CROCE by N.M. PENZER, 2 vol. (1932). The commentaries on these tales are especially valuable. The new translation of Grimm's folktales, *German Folk Tales* by F.P. MAGOUN and A.H. KRAPPE (1960), is convenient for English readers. For folktales of the North American Indians, the American Negroes, and the peoples of Oceania and Israel, the following works are standard: W. MATTHEWS, *Navaho Legends* (1897); S. THOMPSON (ed.), *Tales of the North American Indians* (1929, reprinted 1966), an anthology with exhaustive comparative notes, valid until about 1926; M. JACOBS, *The Content and Style of an Oral Literature: Clackamas Chinook Myths and Tales* (1959), tales of a vanishing North Pacific tribe; W.A. LESSA, *Tales from Ulithi Atoll: A Comparative Study in Oceanic Folklore* (1961); K. LUOMALA, *Voices on the Wind. Polynesian Myths and Chants* (1955); R.M. DORSON, *American Negro Folktales* (1967); and D. NOY and D. BEN-AMOS (eds.), *Folktales of Israel* (1963). Types and classifications of folktales and legends are: A.A. AARNE, *The Types of the Folktale,* 2nd rev., trans. and enl. by S. THOMPSON (1961), a standard list of tales of old world provenance; S. THOMPSON, *Motif-Index of Folk Literature,* rev. ed., 6 vol. (1955–58); and R.T. CHRISTIANSEN, *The Migratory Legends* (1958), a classification of European legends. A good example of a survey of tales of a particular country is S. O'SUILLEABHAIN and R.T. CHRISTIANSEN, *Types of the Irish Folktale* (1963). A general introduction to folk song is G. HERZOG, "Song: Folksong, and the Music of Folksong," in *Funk and Wagnall's Standard Dictionary of Folklore,* vol. 2, pp. 1032–1050 (1949–50). A comprehensive introduction and listing of all the classical fables is in B.E. PERRY, *Babrius, and Phaedrus* (1965). The proverb, the riddle, and the charm are treated in A. TAYLOR, *The Proverb* (1962), *English Riddles from Oral Tradition* (1951); and W.R. BASCOM, *Ifa Divination: Communication Between Gods and Men in W. Africa* (1969). Important also is the work of L. DEGH, *Folktales and Society* (1969), a study of a Hungarian storyteller; A. DUNDES, *The Study of Folklore* (1965); V.A. PROPP, *Morphology of the Folktale* (1958); and T.A. SEBEOK, *Myth. A Symposium* (1965), a collection of theoretical treatments of mythology. An outstanding discussion of narrative folk song is A.B. LORD, *The Singer of Tales* (1960). A model historical and geographical study is W.E. ROBERTS, *The Tale of the Kind and the Unkind Girls* (1958).

Folk music: Among the scholarly periodicals devoted primarily to folk music, the most important are the *International Folk Music Council Yearbook* (1969–), formerly the *International Folk Music Council Journal; Ethnomusicology* (1953–); and the *Journal of American Folklore* (1888–). General works on folk music of Europe and the Americas are BRUNO NETTL, *Folk and Traditional Music of the Western Continents* (1965); WERNER DANCKERT, *Das europäische Volkslied* (1939); the lengthy and subdivided article on the folk music of many countries in *Grove's Dictionary of Music and Musicians,* 5th ed. (1955); and GEORGE HERZOG, "Song," in *Funk and Wagnalls Standard Dictionary of Folklore, Mythology and Legend* (1950). An im-

portant survey of the world's folk music in its relationship to certain characteristics of cultures is ALAN LOMAX, *Folk Song Style and Culture* (1968). WALTER WIORA, *Europäischer Volksgesang* (1952), provides an anthology of formal and melodic types in folk music; *Europäische Volksmusik und abendländische Tonkunst* (1957) explores the relationships between folk and classical music throughout European history. BELA BARTOK, *Hungarian Folk Music* (1931), is a classic study of one folk music style. A.B. LORD, *The Singer of Tales* (1960), deals with the epic traditions of eastern Europe. C.J. SHARP (comp.), *English Folk Songs from the Southern Appalachians*, 2 vol. (1932), is the pioneer collection of Anglo-American song; the total tune repertory of the most important traditional ballads in England and North America is published in B.H. BRONSON, *The Traditional Tunes of the Child Ballads*, 4 vol. (1959–70). The best general survey of Anglo-American folk song is R.D. ABRAHAMS and G. FOSS, *Anglo-American Folksong Style* (1968). The history of folk music research is treated in D.K. WILGUS, *Anglo-American Folksong Scholarship Since 1898* (1959). The modern urban folk song movement has given rise to a series of popular folk music periodicals, most of them ephemeral; notable American examples include *Broadside* (1962–), and *Sing Out!* (1950–).

Folk dance: V. ALFORD and R. GALLOP, *The Traditional Dance* (1935), authoritative, popular account of Europe's ancient ritual dances; C.M. BARBEAU (comp.), *Roundelays: Folk Dances and Games Collected in Canada and New Zealand* (1958), children's mimed rounds from French Canada, with descriptions, music, and bilingual texts; E. BURCHENAL, *Folk-Dances from Old Homelands* (1922), descriptions of European folk dances, for use in schools; N. CHILKOVSKY, *American Bandstand Dances in Labanotation* (1959), notations of jazz dances, for reconstruction by experts in the Laban system of notation; L.K. CZARNOWSKI, *Dances of Early California Days* (1950), splendid historical account, with descriptions and music, for use in schools; A.S. DUGGAN *et al.*, *The Folk Dance Library*, 5 vol. (1948), descriptions of dances from European and North American nations, with diagrams, music, and historical background, for school use; D.N. KENNEDY, *England's Dances* (1949), survey and interpretation of British ritual and folk dances; G.P. KURATH, *Iroquois Music and Dance*, U.S. Bureau of American Ethnology Bull. 187 (1964), and *Music and Dance of the Tewa Pueblos* (1970), analysis of dances and music, with many notation scores, interpretations, and background notes, not for reconstruction; LA MERI, *Spanish Dancing* (1948), skilled presentation of Spanish folk dances, with regional distinctions and some analysis of movement routines; J. LAWSON, *European Folk Dance* (1953), analysis of regional European steps and rhythms, with examples, useful facts, and questionable hypotheses; L. LEKIS, *Folk Dances of Latin America* (1958), exhaustive, annotated bibliography, with reliable comments on meanings and forms; M. MAYO, *American Square Dance*, rev. ed. (1948), a practical book for folk dance groups, with careful instructions and some music; C.J. SHARP (ed.), *The Country Dance Book*, 6 pt. (1909–22), exhaustive treatise on British folk dances by a scholarly pioneer, with diagrams and music; H.L. SPREEN, *Folk-Dances of South India* (1945), unusual, exotic material for schools, with movement descriptions, music, and bilingual texts; MARIA LEACH (ed.), *Dictionary of Folklore, Mythology and Legend*, vol. 1 (1949), definitions and scholarly interpretations.

Visual arts of the folk tradition: H.T. BOSSERT, *Ornamente der Volkskunst* (1949; Eng. trans., *Folk Art of Europe*, trans. by SYBIL MOHOLY NAGY, 1953, reprinted 1964), selection by the author from his *Volkskunst im Europa* (1926), a major compilation of folk designs, largely from textiles; D.P. BRANCH, *Folk Architecture of the East Mediterranean* (1966), includes Greek islands, central and southern Italy, with photos and diagrams; R.F. BUSSABARGER and B.D. ROBINS, *The Everyday Art of India* (1968), with glossary; ALFONSO CASO and D.F. RUBIN *et al.*, *Arte popular de México* (1963), a special issue of *Artes de México*, authoritative for crafts; E.O. CHRISTENSEN, *The Index of American Design* (1950), selections from a Federal Art Project study covering pre-1700–*c.* 1900; H.J. HANSEN (ed.), *Europas Volkskunst und die europäisch beeinflusste Volkskunst Amerikas* (1967; Eng. trans., *European Folk Art in Europe and the Americas*, 1968), country by country, chiefly European, with over 600 illustrations; M. HARMON *et al.*, "Folk Art," *Encyclopedia of World Art*, vol. 5, col. 451–506 (1961), a worldwide sampling of the arts, with extensive bibliography to *c.* 1960; STELLA KRAMRISCH, *Unknown India* (1968), an exhibition catalog of ritual and tribal folk art; FRANCES LICHTEN, *Folk Art of Rural Pennsylvania* (1946), German-American motifs and products; JEAN LIPMAN, *American Primitive Painting* (1942), pioneering study of folk painters; P.S. LORD and D.J. FOLEY, *The Folk Arts and Crafts of New England* (1965), over 500 illustrations of crafts; HUGO MUNSTERBERG, *The Folk Arts of Japan* (1958), includes the modern folk-art movement and living folk arts; BERNARD RUDOFSKY, *Architecture Without Architects* (1969), on primitive and vernacular styles all over the world; R.T. WILCOX, *Folk and Festival Costume of the World* (1965), over 150 regions, 111 plates, and bibliography.

Food Processing

Food processing is generally understood to encompass all methods by which raw foodstuffs are rendered suitable for cooking, consumption, or storage. This article treats the principal processing methods and products of the food-processing industry. Similar aspects of the beverage industry are treated in the article BEVERAGE PRODUCTION. For a discussion of the cultivation of food crops, see FARMING AND AGRICULTURAL TECHNOLOGY. For information on the nutritional role of various foods in the human diet, see NUTRITION. The culinary aspects of food preparation and consumption are treated in the article GASTRONOMY.

For more information on the coverage of topics related to food processing in both the *Macropædia* and *Micropædia,* see the *Propædia,* section 731, and the *Index.* (Ed.)

The article is divided into the following sections:

Food preservation and storage

Techniques for preserving food from natural deterioration, following harvest or slaughter, date to prehistoric times. Among the oldest methods of preservation are drying, refrigeration, and fermentation. Modern methods include canning, pasteurization, freezing, irradiation, and the addition of chemicals. Advances in packaging materials have played an important role in modern food preservation.

SPOILAGE MECHANISMS

Food spoilage may be defined as any change that renders food unfit for human consumption. These changes may be caused by various factors, including contamination by microorganisms, infestation by insects, or degradation by endogenous enzymes (those present naturally in the food). In addition, physical and chemical changes, such as the tearing of plant or animal tissues or the oxidation of certain constituents of food, may promote food spoilage. Foods obtained from plant or animal sources begin to spoil soon after harvest or slaughter. The enzymes contained in the cells of plant and animal tissues may be released as a result of any mechanical damage inflicted during postharvest handling. These enzymes begin to break down the cellular material. The chemical reactions catalyzed by the enzymes result in the degradation of food quality, such as the development of off-flavours, the deterioration of texture, and the loss of nutrients. The typical microorganisms that cause food spoilage are bacteria (*e.g., Lactobacillus*), yeasts (*e.g., Saccharomyces*), and molds (*e.g., Rhizopus*).

Microbial contamination. Bacteria and fungi (yeasts and molds) are the principal types of microorganisms that cause food spoilage and food-borne illnesses. Foods may be contaminated by microorganisms at any time during harvest, storage, processing, distribution, handling, or preparation. The primary sources of microbial contamination are soil, air, animal feed, animal hides and intestines, plant surfaces, sewage, and food processing machinery or utensils.

Bacteria. Bacteria are unicellular organisms that have a simple internal structure compared with the cells of other organisms. The increase in the number of bacteria in a population is commonly referred to as bacterial growth by microbiologists. This growth is the result of the division of one bacterial cell into two identical bacterial cells, a process called binary fission. Under optimal growth conditions, a bacterial cell may divide approximately every 20 minutes. Thus, a single cell can produce almost 70 billion cells in 12 hours. The factors that influence the growth of bacteria include nutrient availability, moisture, pH, oxygen levels, and the presence or absence of inhibiting substances (*e.g.,* antibiotics).

Growth conditions for bacteria

The nutritional requirements of most bacteria are chemical elements such as carbon, hydrogen, oxygen, nitrogen, phosphorus, sulfur, magnesium, potassium, sodium, calcium, and iron. The bacteria obtain these elements by utilizing gases in the atmosphere and by metabolizing certain food constituents such as carbohydrates and proteins.

Temperature and pH play a significant role in controlling the growth rates of bacteria. Bacteria may be classified into three groups based on their temperature requirement for optimal growth: thermophiles (55°–75° C, or 130°–170° F), mesophiles (20°–45° C, or 70°–115° F), or psychrotrophs (10°–20° C, or 50°–70° F). In addition, most bacteria grow best in a neutral environment (pH equal to 7).

Bacteria also require a certain amount of available water for their growth. The availability of water is expressed as water activity and is defined by the ratio of the vapour pressure of water in the food to the vapour pressure of pure water at a specific temperature. Therefore, the water activity of any food product is always a value between 0 and 1, with 0 representing an absence of water and 1 representing pure water. Most bacteria do not grow in foods with a water activity below 0.91, although some halophilic bacteria (those able to tolerate high salt concentrations) can grow in foods with a water activity lower than 0.75. Growth may be controlled by lowering the water activity—either by adding solutes such as sugar, glycerol, and salt or by removing water through dehydration.

The oxygen requirements for optimal growth vary considerably for different bacteria. Some bacteria require the presence of free oxygen for growth and are called obligate aerobes, whereas other bacteria are poisoned by the presence of oxygen and are called obligate anaerobes. Facultative anaerobes are bacteria that can grow in both the presence or absence of oxygen. In addition to oxygen concentration, the oxygen reduction potential of the growth medium influences bacterial growth. The oxygen reduction potential is a relative measure of the oxidizing or reducing capacity of the growth medium.

When bacteria contaminate a food substrate, it takes some time before they start growing. This lag phase is the period when the bacteria are adjusting to the environment. Following the lag phase is the log phase, in which population grows in a logarithmic fashion. As the population grows, the bacteria consume available nutrients and produce waste products. When the nutrient supply is depleted, the growth rate enters a stationary phase in which the number of viable bacteria cells remains the same. During the stationary phase, the rate of bacterial cell growth is equal to the rate of bacterial cell death. When the rate of cell death becomes greater than the rate of cell growth, the population enters the decline phase.

Table 1: Enzymes That Cause Food Spoilage

enzyme	food product	spoilage action
Ascorbic acid oxidase	vegetables	destruction of vitamin C
Lipase	cereals	discoloration
	milk	hydrolytic rancidity
	edible oils	hydrolytic rancidity
Lipoxygenase	vegetables	destruction of vitamin A, off-flavour
Pectic enzyme	citrus juices	destruction of pectic substances
	fruits	excessive softening
Peroxidase	fruits	browning
Polyphenoloxidase	fruits, vegetables	browning, off-flavour, vitamin loss
Protease	eggs	reduce shelf life of fresh and dried whole eggs
	crab, lobster	overtenderization
	flour	reduction of gluten formation
Thiaminase	meats, fish	destruction of thiamine

A bacterial population is expressed either per gram or per square centimetre of surface area. Rarely does the total bacterial population exceed 10^{10} cells per gram. A population of less than 10^6 cells per gram does not cause any noticeable spoilage except in raw milk. Populations of between 10^6 and 10^7 cells per gram cause spoilage in some foods; for example, they can generate off-odours in vacuum-packaged meats. Populations of between 10^7 and 10^8 cells per gram produce off-odours in meats and some vegetables. At levels above 5×10^7 cells per gram, most foods exhibit some form of spoilage.

When the conditions for bacterial cell growth are unfavourable (*e.g.,* low or high temperatures or low moisture content), several species of bacteria can produce resistant cells called endospores. Endospores are highly resistant to heat, chemicals, desiccation (drying out), and ultraviolet light. The endospores may remain dormant for long periods of time. When conditions become favourable for growth (*e.g.,* thawing of meats), the endospores germinate and produce viable cells that can begin exponential growth.

Fungi. The two types of fungi that are important in food spoilage are yeasts and molds. Molds are multicellular fungi that reproduce by the formation of spores (single cells that can grow into a mature fungus). Spores are formed in large numbers and are easily dispersed through the air. Once these spores land on a food substrate, they can grow and reproduce if conditions are favourable. Yeasts are unicellular fungi that are much larger than bacterial cells. They reproduce by cell division (binary fission) or budding.

Growth conditions for fungi

The conditions affecting the growth of fungi are similar to those affecting bacteria. Both yeasts and molds are able to grow in an acidic environment (pH less than 7). The pH range for yeast growth is 3.5 to 4.5 and for molds is 3.5 to 8.0. The low pH of fruits is generally unfavourable for the growth of bacteria, but yeasts and molds can grow and cause spoilage in fruits. For example, species of the fungal genus *Colletotrichum* cause crown rot in bananas. Yeasts promote fermentation in fruits by breaking down sugars into alcohol and carbon dioxide. The amount of available water in a food product is also critical for the growth of fungi. Yeasts are unable to grow at a water activity of less than 0.9, and molds are unable to grow at a water activity below 0.8.

Control of microbial contamination. The most common methods used either to kill or to reduce the growth of microorganisms are the application of heat, the removal of water, the lowering of temperature during storage, the reduction of pH, the control of oxygen and carbon dioxide concentrations, and the removal of the nutrients needed for growth. The use of chemicals as preservatives is strictly regulated by governmental agencies such as the Food and Drug Administration (FDA) in the United States. Although a chemical may have preservative functions, its safety must be proved before it may be used in food products. To suppress yeast and mold growth in foods, a number of chemical preservatives are permitted. In the United States, the list of such chemicals, known as GRAS (Generally Recognized as Safe), includes compounds such as benzoic acid, sodium benzoate, propionic acid, sorbic acid, and sodium diacetate.

Chemical deterioration. *Enzymatic reactions.* Enzymes are large protein molecules that act as biological catalysts, accelerating chemical reactions without being consumed to any appreciable extent themselves. The activity of enzymes is specific for a certain set of chemical substrates, and it is dependent on both pH and temperature.

The living tissues of plants and animals maintain a balance of enzymatic activity. This balance is disrupted upon harvest or slaughter. In some cases, enzymes that play a useful role in living tissues may catalyze spoilage reactions following harvest or slaughter. For example, the enzyme pepsin is found in the stomach of all animals and is involved in the breakdown of proteins during the normal digestion process. However, soon after the slaughter of an animal, pepsin begins to break down the proteins of the organs, weakening the tissues and making them more susceptible to microbial contamination. After the harvesting of fruits, certain enzymes remain active within the cells of the plant tissues. These enzymes continue to catalyze the biochemical processes of ripening and may eventually lead to rotting, as can be observed in bananas. In addition, oxidative enzymes in fruits continue to carry out cellular respiration (the process of using oxygen to metabolize glucose for energy). This continued respiration decreases the shelf life of fresh fruits and may lead to spoilage. Respiration may be controlled by refrigerated storage or modified-atmosphere packaging. Table 1 lists a number of enzymes involved in the degradation of food quality.

Autoxidation. The unsaturated fatty acids present in the lipids of many foods are susceptible to chemical breakdown when exposed to oxygen. The oxidation of unsaturated fatty acids is autocatalytic; that is, it proceeds by a free-radical chain reaction. Free radicals contain an unpaired electron (represented by a dot in the molecular formula) and, therefore, are highly reactive chemical molecules. The basic mechanisms in a free-radical chain reaction involve initiation, propagation, and termination steps (Figure 1). Under certain conditions, in initiation a free-radical molecule ($X\cdot$) present in the food removes a hydrogen (H) atom from a lipid molecule, producing a lipid radical ($L\cdot$). This lipid radical reacts with molecular oxygen (O_2) to form a peroxy radical ($LOO\cdot$). The peroxy radical removes a hydrogen atom from another lipid molecule and the reaction starts over again (propagation). During the propagation steps, hydroperoxide molecules (LOOH) are formed that may break down into alkoxy ($LO\cdot$) and peroxy radicals plus water (H_2O). The lipid, alkoxy, and peroxy radicals may combine with one another (or other radicals) to form stable, nonpropagating products (termination). These products result in the development of rancid off-flavours. In addition to promoting rancidity, the free radicals and peroxides produced in these reactions may have other negative effects, such as the bleaching of food colour and the destruction of vitamins A, C, and E. This type of deterioration is prevalent in fried snacks, nuts, cooking oils, and margarine.

Rancidity

Initiation: $X\cdot + LH \rightarrow L\cdot + XH$

Propagation:
$$L\cdot + O_2 \rightarrow LOO\cdot$$
$$LOO\cdot + LH \rightarrow LOOH + L\cdot$$
$$2LOOH \rightarrow LO\cdot + LOO\cdot + H_2O$$

Termination: $L\cdot$, $LO\cdot$, $LOO\cdot$ → a number of stable nonpropagating species

Figure 1: The autoxidation of unsaturated fatty acids.

Maillard reaction. Another chemical reaction that causes major food spoilage is nonenzymatic browning, also known as the Maillard reaction. This reaction takes place between reducing sugars (simple monosaccharides capable of carrying out reduction reactions) and the amino group of proteins or amino acids present in foods. The products of the Maillard reaction lead to a darkening of colour, reduced solubility of proteins, development of bitter flavours, and reduced nutritional availability of certain amino acids such as lysine. The rate of this reaction is influenced by the water activity, temperature, and pH of the food product. Nonenzymatic browning causes spoilage during the storage of dry milk, dry whole eggs, and breakfast cereals.

Light-induced reactions. Light influences a number of chemical reactions that lead to spoilage of foods. These light-induced reactions include the destruction of chlorophyll (the photosynthetic pigment that gives plants their green colour), resulting in the bleaching of certain vegetables; the discoloration of fresh meats; the destruction of riboflavin in milk; and the oxidation of vitamin C and carotenoid pigments (a process called photosensitized oxidation). The use of packaging material that prevents exposure to light is one of the most effective means of preventing light-induced chemical spoilage.

LOW-TEMPERATURE PRESERVATION

Storage at low temperatures prolongs the shelf life of many foods. In general, low temperatures reduce the growth rates of microorganisms and slow many of the physical and chemical reactions that occur in foods.

Refrigeration. The life of many foods may be increased by storage at temperatures below 4° C (40° F). Commonly refrigerated foods include fresh fruits and vegetables, eggs, dairy products, and meats. Some foods, such as tropical fruits (*e.g.,* bananas), are damaged if exposed to low temperatures. Also, refrigeration cannot improve the quality of decayed food; it can only retard deterioration. One problem of modern mechanical refrigeration—that of dehydration of foods due to moisture condensation—has been overcome through humidity control mechanisms within the storage chamber and by appropriate packaging techniques.

Freezing. Freezing and frozen storage provide an excellent means of preserving the nutritional quality of foods. At subfreezing temperatures the nutrient loss is extremely slow for the typical storage period used in commercial trade.

History. Early freezing methods were based on the principle that mixing salt with ice results in temperatures well below 0° C (32° F). By the end of the 19th century, this method was being used commercially in the United States to freeze fish and poultry. By the 1920s Clarence Birdseye had developed two processes for freezing fish based on his quick freezing theory. His first patent, describing a method for preserving piscatorial products, involved placing food between two metal plates that were chilled by a calcium chloride solution to approximately −40° C (−40° F). The second process utilized two hollow metal plates that were cooled to −25° C (−13° F) by vaporization of ammonia. This freezing apparatus was the forerunner of the multiple plate freezer that is widely used in the modern food industry.

Crystal growth

The freezing process. The freezing of food involves lowering its temperature below 0° C, resulting in the gradual conversion of water, present in the food, into ice. Freezing is a crystallization process that begins with a nucleus or a seed derived from either a nonaqueous particle or a cluster of water molecules (formed when the temperature is reduced below 0° C). This seed must be of a certain size to provide an adequate site for the crystal to begin to grow. If physical conditions are conducive to the presence of numerous seeds for crystallization, then a large number of small ice crystals will form. However, if only a few seeds are initially available, then a few ice crystals will form and each will grow to a large size. The size and the number of ice crystals influence the final quality of many frozen foods; for example, the smooth texture of ice cream indicates the presence of a large number of small ice crystals.

In pure water, the freezing process is initiated by lowering the temperature to slightly below 0° C, called supercooling. As ice crystals begin to grow, the temperature returns to the freezing point. During the conversion of liquid water to ice, the temperature of the system does not change. The heat removed during this step is called the latent heat of fusion (equivalent to 333 joules per gram of water). Once all the water is converted to ice, any additional removal of heat will result in a decrease in the temperature below 0° C.

The freezing of foods exhibits a number of important differences from the freezing of pure water. Foods do not freeze at 0° C. Instead, owing to the presence of different soluble particulates (solutes) in the water present in foods, most foods begin to freeze at a temperature between 0° and −5° C (32° and 23° F). In addition, the removal of latent heat in foods during freezing does not occur at a fixed temperature. As the water present in the food freezes into ice, the remaining water becomes more concentrated with solutes. As a result, the freezing point is further depressed. Therefore, foods have a zone of maximum ice crystal formation that typically extends from −1° to −4° C (30° to 25° F). Damage to food quality during freezing can be minimized if the temperature of the product is brought below this temperature range as quickly as possible.

Industrial freezers. The rate at which heat is removed from a food during freezing depends on how fast heat can travel within the food and how efficiently it can be liberated from the surface of the food into the surrounding atmosphere. Industrial freezers remove heat from the surface of a food as rapidly as possible. There are several types of industrial freezers, including air-blast tunnel freezers, belt freezers, fluidized-bed freezers, plate freezers, and cryogenic freezers.

Air-blast freezers

In air-blast tunnel freezers and belt freezers, precooled air at approximately −40° C is blown over the food products. Packaged foods, such as fruits, vegetables, bakery goods, poultry, meats, and prepared meals, are usually frozen in air-blast tunnels. The packages are placed onto dollies or hand trucks and then rolled into the freezer tunnels. In a belt freezer, food is placed on a conveyor belt that moves through a freezing zone. Bakery goods, chicken parts, and meat patties are frozen using a belt freezer.

Fluidized-bed freezers are used to freeze particulate foods such as peas, cut corn, diced carrots, and strawberries. The foods are placed on a mesh conveyor belt and moved through a freezing zone in which cold air is directed upward through the mesh belt and the food particulates begin to tumble and float. This tumbling exposes all sides of the food to the cold air and minimizes the resistance to heat transfer at the surface of the food.

Plate freezers are used to freeze flat products, such as pastries, fish fillets, and beef patties, as well as irregular-shaped vegetables that are packaged in brick-shaped containers, such as asparagus, cauliflower, spinach, and broccoli. The food is firmly pressed betwcen metal plates that are cooled to subfreezing temperatures by internally circulating refrigerants.

Cryogenic freezing is used to freeze food at an extremely fast rate. The food is moved through a spray of liquid nitrogen or directly immersed in liquid nitrogen. The liquid nitrogen boils around the food at a temperature of −196° C (−321° F) and extracts a large amount of heat.

Quality of frozen foods. Improper freezing or storage of foods may result in detrimental quality changes. When foods with high amounts of water are frozen slowly, they may experience a loss of fluid, called drip, upon thawing. This fluid loss causes dehydration and nutrient loss in frozen food products.

During frozen storage, the ice crystals present in foods may enlarge in size, producing undesirable changes in texture. This phenomenon is commonly observed when the storage temperature is allowed to fluctuate. For example, ice cream stored in an automatic defrosting domestic freezer becomes sandy in texture because the ice crystals increase in size as the temperature of the system fluctuates.

Improperly packaged frozen foods lose small amounts of moisture during storage, resulting in surface dehydration (commonly called freezer burn). Frozen meats with freezer burn have the appearance of brown paper and quickly become rancid. Freezer burn can be minimized by the use of tightly wrapped packages and the elimination of fluctuating temperatures during storage.

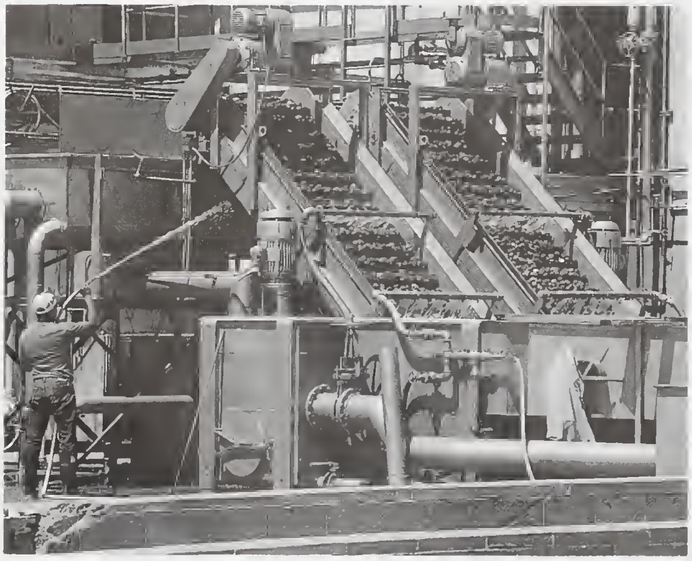

Figure 2: Spray washing of harvested tomatoes prior to processing.

THERMAL PROCESSING

Thermal processing is defined as the combination of temperature and time required to eliminate a desired number of microorganisms from a food product.

Canning. Nicolas Appert, a Parisian confectioner by trade, is credited with establishing the heat processing of foods as an industry. In 1810 he received official recognition for his process of enclosing food in bottles, corking the bottles, and placing the bottles in boiling water for various periods of time. In the same year Peter Durand received a British patent for the use of containers made of glass, pottery, tin, or other metals for the heat preservation of foods. In 1822 Ezra Daggett and Thomas Kensett announced the availability of preserved foods in tin cans in the United States. Tin-coated steel containers, made from 98.5 percent sheet steel with a thin coating of tin, soon became common. These cans had a double seamed top and bottom to provided an airtight seal and could be manufactured at high speeds.

The establishment of the canning process on a more scientific basis did not occur until 1896, when the microorganism *Clostridium botulinum,* with its lethal toxin causing botulism, was discovered by Émile van Ermengem.

Presterilization procedures. Selected crop varieties are grown specially for canning purposes. The harvesting schedules of the crops are carefully selected to conform to the cannery operations. A typical canning operation involves cleaning, filling, exhausting, can sealing, heat processing, cooking, labeling, casing, and storage. Most of these operations are performed using high-speed, automatic machines.

Cleaning involves the use of shakers, rotary reel cleaners, air blasters, water sprayers (as shown in Figure 2), or immersion washers. Any inedible or extraneous material is removed before washing, and only potable water is used in the cleaning systems.

Evacuation of air

Automatic filling machines are used to place the cleaned food into cans or other containers, such as glass jars or plastic pouches. When foods containing trapped air, such as leafy vegetables, are canned, the air must be removed from the cans prior to closing and sealing the lids by a process called exhausting. Exhausting is accomplished using steam exhaust hoods or by creation of a vacuum.

Immediately after exhausting, the lids are placed on the cans and the cans are sealed. An airtight seal is achieved between the lid and the rim of the can using a thin layer of gasket or compound. The anaerobic conditions prevent the growth of oxygen-requiring microorganisms. In addition, many of the spores of anaerobic microorganisms are less resistant to heat and are easily destroyed during the heat treatment.

Sterilization. The time and temperature required for the sterilization of foods are influenced by several factors, including the type of microorganisms found on the food, the size of the container, the acidity or pH of the food, and the method of heating.

The thermal processes of canning are generally designed to destroy the spores of the bacterium *C. botulinum.* This microorganism can easily grow under anaerobic conditions, producing the deadly toxin that causes botulism. Sterilization requires heating to temperatures greater than 100° C (212° F). However, *C. botulinum* is not viable in acidic foods that have a pH less than 4.6. These foods can be adequately processed by immersion in water at temperatures just below 100° C.

The sterilization of low-acid foods (pH greater than 4.6) is generally carried out in steam vessels called retorts at temperatures ranging from 116° to 129° C (240° to 265° F). The retorts are controlled by automatic devices, and detailed records are kept of the time and temperature treatments for each lot of processed cans. At the end of the heating cycle, the cans are cooled under water sprays or in water baths to approximately 38° C (100° F) and dried to prevent any surface rusting. The cans are then labeled, placed in fibreboard cases either by hand or machine, and stored in cool, dry warehouses.

Quality of canned foods. The sterilization process is designed to provide the required heat treatment to the slowest heating location inside the can, called the cold spot. The areas of food farthest from the cold spot get a more severe heat treatment that may result in overprocessing and impairment of the overall quality of the product. Flat, laminated pouches can reduce the heat damage caused by overprocessing.

A significant loss of nutrients, especially heat-labile vitamins, may occur during the canning process. In general, canning has no major effect on the carbohydrate, protein, or fat content of foods. Vitamins A and D and beta-carotene are resistant to the effects of heat. However, vitamin B_1 is sensitive to thermal treatment and the pH of the food. Although the anaerobic conditions of canned foods have a protective effect on the stability of vitamin C, it is destroyed during long heat treatments.

The ends of processed cans are slightly concave because of the internal vacuum created during sealing. Any bulging of the ends of a can may indicate a deterioration in quality due to mechanical, chemical, or physical factors. This bulging may lead to swelling and possible explosion of the can.

Pasteurization. Pasteurization is the application of heat to a food product in order to destroy pathogenic (disease-producing) microorganisms, to inactivate spoilage-causing enzymes, and to reduce or destroy spoilage microorganisms. The relatively mild heat treatment used in the pasteurization process causes minimal changes in the sensory and nutritional characteristics of foods compared to the severe heat treatments used in the sterilization process.

Pasteurizing acidic and basic foods

The temperature and time requirements of the pasteurization process are influenced by the pH of the food. When the pH is below 4.5, spoilage microorganisms and enzymes are the main targets of pasteurization. For example, the pasteurization process for fruit juices is aimed at inactivating certain enzymes such as pectinesterase and polygalacturonase. The typical processing conditions for the pasteurization of fruit juices include heating to 77° C (171° F) and holding for 1 minute, followed by rapid cooling to 7° C (45° F). In addition to inactivating enzymes, these conditions destroy any yeasts or molds that may lead to spoilage. Equivalent conditions capable of reducing spoilage microorganisms involve heating to 65° C (149° F) and holding for 30 minutes or heating to 88° C (190° F) and holding for 15 seconds.

When the pH of a food is greater than 4.5, the heat treatment must be severe enough to destroy pathogenic bacteria. In the pasteurization of milk, the time and temperature conditions target the pathogenic bacteria *Mycobacterium tuberculosis, Coxiella burnetti,* and *Brucella abortus.* The typical heat treatment used for pasteurizing milk is 72° C (162° F) for 15 seconds, followed by rapid cooling to 7° C. Other equivalent heat treatments include heating to 63° C (145° F) for 30 minutes, 90° C (194° F) for 0.5 second, and 94° C (201° F) for 0.1 second. The high-temperature-short-time (HTST) treatments cause less damage to the nutrient composition and sensory characteristics of foods and therefore are preferred over the low-temperature-long-time (LTLT) treatments.

Since the heat treatment of pasteurization is not severe enough to render a product sterile, additional methods such as refrigeration, fermentation, or the addition of chemicals are often used to control microbial growth and to extend the shelf life of a product. For example, the pasteurization of milk does not kill thermoduric bacteria (those resistant to heat), such as *Lactobacillus* and *Streptococcus,* or thermophilic bacteria (those that grow at high temperatures), such as *Bacillus* and *Clostridium.* Therefore, pasteurized milk must be kept under refrigerated conditions.

Liquid foods such as milk, fruit juices, beers, wines, and liquid eggs are pasteurized using plate-type heat exchangers. Wine and fruit juices are normally deaerated prior to pasteurization in order to remove oxygen and minimize oxidative deterioration of the products. Plate-type heat exchangers consist of a large number of thin, vertical steel plates that are clamped together in a frame. The plates are separated by small gaskets that allow the liquid to flow between each successive plate. The liquid product and heating medium (*e.g.,* hot water) are pumped through alternate channels, and the gaskets ensure that the liquid product and heating or cooling mediums are kept separate. Plate-type heat exchangers are effective in rapid heating and cooling applications. After the pasteurization process is completed, the product is packaged under aseptic conditions to prevent recontamination of the product.

Aseptic processing. The aseptic process involves placing a sterilized product into a sterilized package that is then sealed under sterile conditions. It began in 1914 with the development of sterile filters for use in the wine industry. However, because of unreliable machinery, it remained commercially unsuccessful until 1948 when William McKinley Martin helped develop the Martin system, which later became known as the Dole Aseptic Canning System. This system involved the sterilization of liquid foods by rapidly heating them in tubular heat exchangers, followed by holding and cooling steps. The cans and lids were sterilized with superheated steam, and the sterilized containers were filled with the sterile liquid food. The lids were then sealed in an atmosphere of superheated steam. By the 1980s hydrogen peroxide was being used throughout Europe and the United States for the sterilization of polyethylene surfaces.

Commercial sterility. In aseptic processing the thermal process is based on achieving commercial sterility—*i.e.,* no more than 1 nonsterile package for every 10,000 processed packages. The aseptic process uses the high-temperature-short-time (HTST) method in which foods are heated at a high temperature for a short period of time. The time and temperature conditions depend on several factors, such as size, shape, and type of food. The HTST method results in a higher retention of quality characteristics, such as vitamins, odour, flavour, and texture, while achieving the same level of sterility as the traditional canning process in which food is heated at a lower temperature for a longer period of time.

The heating and cooling of liquid foods can be performed using metal plate heat exchangers. These heat exchangers have large surface areas that result in improved heating and cooling rates. Other types of heat exchangers involve surrounding the food with steam or directly injecting steam into the food. Products sterilized with steam are then pumped into a vacuum chamber, where they are cooled rapidly.

Liquid foods that contain large solid particles are heated in scraped-surface heat exchangers. These heat exchangers use blades to continuously scrape the inside surface of the heating chamber. The scraping action protects highly viscous foods from being burned on the heating surface.

Ohmic heating

An alternate method for heating foods, called ohmic heating, passes a low-frequency electric current of 50 to 60 hertz directly through the food. A liquid food containing solids, such as diced fruit, is pumped through a pipe surrounded by electrodes. The product is heated as long as the electrical conductivity of the food is uniform throughout the entire volume. This uniform rate of heating prevents the overprocessing of any individual region of the food. Ohmic heating yields a food product of higher quality than those processed using conventional systems.

Packaging aseptically processed products. The packaging containers used in aseptic processing are sterilized separately before they are used. The packaging machinery is sterilized using steam, sterile gases, or hydrogen peroxide. The sterilization process is generally monitored by culturing a test organism. For example, the remaining presence of the highly heat-resistant bacterium *Bacillus subtilis globigii* can be used as a marker to measure the completeness of sterilization.

Packages must be sealed under sterile conditions, usually using high-temperature sealing plates. Foods that are aseptically processed do not require refrigeration for storage.

Blanching. Blanching is a thermal process used mostly for vegetable tissues prior to freezing, drying, or canning. Before canning, blanching serves several purposes, including cleaning of the product, reducing the microbial load, removing any entrapped gases, and wilting the tissues of leafy vegetables so that they can be easily put into the containers. Blanching also inactivates enzymes that cause deterioration of foods during frozen storage.

Blanching is carried out at temperatures close to 100° C (212° F) for two to five minutes in either a water bath or a steam chamber. Because steam blanchers use a minimal amount of water, extra care must be taken to ensure that the product is uniformly exposed to the steam. Steam blanching leafy vegetables is especially difficult because they tend to clump together. The effectiveness of the blanching treatment is usually determined by measuring the residual activity of an enzyme called peroxidase.

CONTROLLING WATER ACTIVITY

Foods containing high concentrations of water are generally more susceptible to deterioration by microbial contamination and enzymatic activity. The water content of foods can be controlled by removing water through dehydration or by adding solutes to the food. In both cases the concentration of solutes in the food increases and the concentration of water decreases.

Dehydration. Dehydration, or drying, of foods has long been practiced commercially in the production of spaghetti and other starch products. As a result of advances made during World War II, the technique has been applied to a growing list of food products, including fruits, vegetables, skim milk, potatoes, soup mixes, and meats.

Pathogenic (toxin-producing) bacteria occasionally withstand the unfavourable environment of dried foods, causing food poisoning when the product is rehydrated and eaten. Control of bacterial contaminants in dried foods requires high-quality raw materials having low contamination, adequate sanitation in the processing plant, pasteurization before drying, and storage conditions that protect from infection by dust, insects, and rodents or other animals.

Foodstuffs may be dried in air, superheated steam, vacuum, or inert gas or by direct application of heat. Air is the most generally used drying medium, because it is plentiful and convenient and permits gradual drying, allowing sufficient control to avoid overheating that might result in scorching and discoloration. Air may be used both to transport heat to the food being dried and to carry away liberated moisture vapour. The use of other gases requires special moisture recovery systems.

Effect of drying on nutrients

Loss of moisture content produced by drying results in increased concentration of nutrients in the remaining food mass. The proteins, fats, and carbohydrates in dried foods are present in larger amounts per unit weight than in their fresh counterparts, and the nutrient value of most reconstituted or rehydrated foods is comparable to that of fresh items. The biological value of dried protein is dependent, however, on the method of drying. Prolonged exposure to high temperatures can render the protein less useful in the diet. Low-temperature treatment, on the other hand, may increase the digestibility of protein. Some vitamins are sensitive to the dehydration process. For example, in dried meats significant amounts of vitamin C and the B vitamins—riboflavin, thiamine, and niacin—are lost during dehydration.

Dried eggs, meat, milk, and vegetables are ordinarily packaged in tin or aluminum containers. Fibreboard or other types of material may be employed but are less satisfactory than metal, which offers protection against insects and moisture loss or gain and which permits packaging with an inert gas.

In-package desiccants (drying agents) improve storage stability of dchydrated white potatoes, sweet potatoes, cabbage, carrots, bcets, and onions and give substantial protection against browning. Retention of ascorbic acid (vitamin C) is markedly improved by packaging at temperatures up to 49° C (120° F); the packaging gas may be either nitrogcn or air.

Freeze-drying process

A related technique, freezc-drying, employs high vacuum conditions, pcrmitting establishment of specific tcmperaturc and prcssure conditions. The raw food is frozen, and thc low pressurc conditions causc the ice in the food to sublimate directly into vapour (*i.e.,* it does not transit through the liquid state). Adequate control of processing conditions contributes to satisfactory rehydration, with substantial retention of nutrient, colour, flavour, and texture characteristics.

Concentration of moist foods. Foods with substantial acidity, when concentrated to 65 percent or more soluble solids, may be preserved by mild heat treatments. High acid content is not a requirement for preserving foods concentrated to over 70 percent solids.

Fruit jelly and preserve manufacture, an important fruit by-product industry, is based on the high-solids–high-acid principle, with its moderate heat-treatment requirements. Fruits that possess excellent qualities but are visually unattractive may be preserved and utilized in the form of concentrates, which have a pleasing taste and substantial nutritive value.

Jellies and other fruit preserves are prepared from fruit by adding sugar and concentrating by evaporation to a point where microbial spoilage cannot occur. The prepared product can be stored without hermetic sealing, although such protection is useful to control mold growth, moisture loss, and oxidation. In modern practice, vacuum sealing has replaced the use of a paraffin cover.

The jelly-forming characteristics of fruits and their extracts are due to pectin, a substance present in varying amounts in all fruits. The essential ingredients in a fruit gel are pectin, acid, sugar, and water. Flavouring and colouring agents may be added, and additional pectin and acid may be added to overcome any deficiencies in the fruit itself.

Candied and glacéed fruits are made by slow impregnation of the fruit with syrup until the concentration of sugar in the tissue is sufficiently high to prevent growth of spoilage microorganisms. The candying process is conducted by treating fruits with syrups of progressively increasing sugar concentrations, so that the fruit does not soften into jam or become tough and leathery. After sugar impregnation the fruit is washed and dried. The resulting candied fruit may be packaged and marketed in this condition or may be dipped into syrup, becoming coated with a thin glazing of sugar (glacéed) and again dried.

FERMENTATION AND PICKLING

Although microorganisms are usually thought of as causing spoilage, they are capable under certain conditions of producing desirable effects, including oxidative and alcoholic fermentation. The microorganisms that grow in a food product, and the changes they produce, are determined by acidity, available carbohydrates, oxygen, and temperature. An important food preservation method combines salting to control microorganisms selectively and fermentation to stabilize the treated tissues.

Role of salt

Pickled fruits and vegetables. Fresh fruits and vegetables soften after 24 hours in a watery solution and begin a slow, mixed fermentation-putrefaction. The addition of salt suppresses undesirable microbial activity, creating a favourable environment for the desired fermentation. Most green vegetables and fruit may be preserved by pickling.

When the pickling process is applied to a cucumber, its fermentable carbohydrate reserve is turned into acid, its colour changes from bright green to olive or yellow-green, and its tissue becomes translucent. The salt concentration is maintained at 8 to 10 percent during the first week and is increased 1 percent a week thereafter until the solution reaches 16 percent. Under properly controlled conditions the salted, fermented cucumber, called salt stock, may be held for several years.

Salt stock is not a consumer commodity. It must be freshened and prepared into consumer items. In cucumbers this is accomplished by leaching the salt from the cured cucumber with warm water (43°–54° C [110°–130° F]) for 10 to 14 hours. This process is repeated at least twice, and, in the final wash, alum may be added to firm the tissue and turmeric to improve the colour.

Pickled meat. Meat may be preserved by dry curing or with a pickling solution. The ingredients used in curing and pickling are sodium nitrate, sodium nitrite, sodium chloride, sugar, and citric acid or vinegar.

Various methods are used: the meat may be mixed with dry ingredients; it may be soaked in pickling solution; pickling solution may be pumped or injected into the flesh; or a combination of these methods may be used.

Curing may be combined with smoking. Smoke acts as a dehydrating agent and coats the meat surfaces with various chemicals, including small amounts of formaldehyde.

Deterioration of fermented and pickled products. Fermented foods and pickled products require protection against molds, which metabolize the acid developed and allow the advance of other microorganisms. Fermented and pickled food products placed in cool storage can be expected to remain stable for several months. Longer storage periods demand more complete protection, such as canning.

Nutrient retention in fermented and pickled products is about equal to retention for products preserved by other methods. Carbohydrates usually undergo conversion to acid or to alcohol, but these are also of nutritive value. In some instances, nutrient levels are increased because of the presence of yeasts.

CHEMICAL PRESERVATION

Chemical food preservatives are substances which, under certain conditions, either delay the growth of microorganisms without necessarily destroying them or prevent deterioration of quality during manufacture and distribution. The former group includes some natural food constituents which, when added to foods, retard or prevent the growth of microorganisms. Sugar is used partly for this purpose in making jams, jellies, and marmalades and in candying fruit. The use of vinegar and salt in pickling and of alcohol in brandying also falls in this category. Some chemicals foreign to foods are added to prevent the growth of microorganisms. The latter group includes some natural food constituents such as ascorbic acid (vitamin C), which is added to frozen peaches to prevent browning, and a long list of chemical compounds foreign to foods and classified as antioxidants, bleaching agents, acidulants, neutralizers, stabilizers, firming agents, and humectants.

Benzoates

Organic chemical preservatives. Sodium benzoate and other benzoates are among the principal chemical preservatives. The use of benzoates in certain products in prescribed quantity (usually not exceeding 0.1 percent) is permitted in most countries, some of which require a declaration of its use on the label of the food container. Since free benzoic acid actually is the active agent, benzoates must be used in an acid medium in order to be effective. The ability of cranberries to resist rapid deterioration is attributed to their high benzoic acid content. Benzoic acid is more effective against yeasts than against molds and bacteria.

Other organic compounds used as preservatives include vanillic acid esters, monochloroacetic acid, propionates, sorbic acid, dehydroacetic acid, and glycols.

Inorganic chemical preservatives. Sulfur dioxide and sulfites are perhaps the most important inorganic chemical preservatives. Sulfites are more effective against molds than against yeasts and are widely used in the preservation of fruits and vegetables. Sulfur compounds are extensively used in wine making and, as in most other instances when this preservative is used, much care has to be exercised to keep the concentrations low in order to avoid undesirable effects on flavour.

Oxidizing agents such as nitrates and nitrites are commonly used in the curing of meats.

FOOD IRRADIATION

Food irradiation involves the use of either high-speed electron beams or high-energy radiation with wavelengths smaller than 200 nanometres, or 2000 angstroms (*e.g.*, X rays and gamma rays). These rays contain sufficient energy to break chemical bonds and ionize molecules that lie in their path. The two most common sources of high-energy radiation used in the food industry are cobalt-60 (^{60}Co) and cesium-137 (^{137}Cs). For the same level of energy, gamma rays have a greater penetrating power into foods than high-speed electrons.

The unit of absorbed dose of radiation by a material is denoted as the gray (Gy), one gray being equal to the absorption of one joule of energy by one kilogram of food. The energy possessed by an electron is called an electron volt (eV). One eV is the amount of kinetic energy gained by an electron as it accelerates through an electric potential difference of one volt. It is usually more convenient to use a larger unit such as megaelectron volt (MeV), which is equal to one million electron volts.

Biological effects of irradiation. Irradiation has both direct and indirect effects on biological materials. The direct effects are due to the collision of radiation with atoms, resulting in an ejection of electrons from the atoms. The indirect effects are due to the formation of free radicals (unstable molecules carrying an extra electron) during the radiolysis (radiation-induced splitting) of water molecules. The radiolysis of water molecules produces hydroxyl radicals, highly reactive species that interact with the organic molecules present in foods. The products of these interactions cause many of the characteristics associated with the spoilage of food, such as off-flavours and off-odours.

Killing of bacteria

Positive effects. The bactericidal (bacteria-killing) effect of ionizing radiation is due to damage of the biomolecules of bacterial cells. The free radicals produced during irradiation may destroy or change the structure of cellular membranes. In addition, radiation causes irreversible changes to the nucleic acid molecules (*i.e.*, DNA and RNA) of bacterial cells, inhibiting their ability to grow. Pathogenic bacteria that are unable to produce resistant endospores in foods such as poultry, meats, and seafood can be eliminated by radiation doses of 3 to 10 kilograys. If the dose of radiation is too low, then the damaged DNA can be repaired by specialized enzymes. If oxygen is present during irradiation, the bacteria are more readily damaged. Doses in the range of 0.2 to 0.36 kilograys are required to stop the reproduction of *Trichinella spiralis* (the parasitic worm that causes trichinosis) in pork, although much higher doses are necessary to eliminate it from the meat.

The dose of radiation used on food products is divided into three levels. Radappertization is a dose in the range of 20 to 30 kilograys, necessary to sterilize a food product. Radurization is a dose of 1 to 10 kilograys, that, like pasteurization, is useful for targeting specific pathogens. Radicidation involves doses of less than 1 kilogray for extending shelf life and inhibiting sprouting.

Negative effects. In the absence of oxygen, radiolysis of lipids leads to cleavage of the interatomic bonds in the fat molecules, producing compounds such as carbon dioxide, alkanes, alkenes, and aldehydes. In addition, lipids are highly vulnerable to oxidation by free radicals, a process that yields peroxides, carbonyl compounds, alcohols, and lactones. The consequent rancidity, resulting from the irradiation of high-fat foods, is highly destructive to their sensory quality. To minimize such harmful effects, fatty foods must be vacuum-packaged and held at subfreezing temperatures during irradiation.

Proteins are not significantly degraded at the low doses of radiation employed in the food industry. For this reason irradiation does not inactivate enzymes involved in food spoilage, as most enzymes survive doses of up to 10 kilograys. On the other hand, the large carbohydrate molecules that provide structure to foods are depolymerized (broken down) by irradiation. This depolymerization reduces the gelling power of the long chains of structural carbohydrates. However, in most foods some protection against these deleterious effects is provided by other food constituents. Vitamins A, E, and B$_1$ (thiamine) are also sensitive to irradiation. The nutritional losses of a food product are high if air is not excluded during irradiation.

Safety concerns. Based on the beneficial effects of irradiation on certain foods, several countries have permitted its use for specific purposes, such as the inhibition of sprouting of potatoes, onions, and garlic; the extension of shelf life of strawberries, mangoes, pears, grapes, cherries, red currants, and cod and haddock fillets; and the insect disinfestation of pulses, peanuts, dried fruits, papayas, wheat, and ground-wheat products.

Large-scale studies conducted around the world have concluded that irradiation does not cause harmful reactions in foods. In 1980 a joint committee of the Food and Agriculture Organization (FAO), the International Atomic Energy Agency (IAEA), and the World Health Organization (WHO) declared that an overall average dose of radiation of 10 kilograys was safe for food products. The maximum energy emitted by ^{60}Co and ^{137}Cs is too low to induce radioactivity in food. The energy output of electron-beam generators is carefully regulated, and the recommended energy outputs are too low to cause radioactivity in foods.

PACKAGING

Because packaging helps to control the immediate environment of a food product, it is useful in creating conditions that extend the storage life of a food. Packaging materials commonly used for foods may be classified as flexible (paper, thin laminates, and plastic film), semirigid (aluminum foil, laminates, paperboard, and thermoformed plastic), and rigid (metal, glass, and thick plastic). Plastic materials are widely used in food packaging because they are relatively cheap, lightweight, and easy to form into desired shapes.

Table 2: Nutrient Composition of Selected Raw Cereal Grains
(per 100 grams)

Cereal grain	energy (kcal)	water (g)	carbohydrate (g)	protein (g)	fat (g)	minerals (g)
Barley (pearled)	352	10.09	77.72	9.91	1.16	1.11
Corn (field)	365	10.37	74.26	9.42	4.74	1.20
Millet	378	8.67	72.85	11.02	4.22	3.25
Oats (oatmeal)	384	8.80	67.00	16.00	6.30	1.90
Rice (brown; long-grain)	370	10.37	77.24	7.94	2.92	1.53
Rye	335	10.95	69.76	14.76	2.50	2.02
Sorghum	339	9.20	74.63	11.30	3.30	1.57
Wheat (hard red winter)	327	13.10	71.18	12.61	1.54	1.57

Barrier properties of packaging materials

The selective permeability of polymer-based materials to gases, such as carbon dioxide and oxygen, as well as light and moisture, has led to the development of modified-atmosphere packaging. If the barrier properties are carefully selected, a packaging material can maintain a modified atmosphere inside the package and thus extend the shelf life of the food product.

Dehydrated foods must be protected from moisture during storage. Packaging materials such as polyvinyl chloride, polyvinylidene chloride, and polypropylene offer low moisture permeability. Similarly, packaging materials with low gas permeability are used for fatty foods in order to minimize oxidation reactions. Because fresh fruits and vegetables respire, they require packaging materials, such as polyethylene, that have high permeability to gases.

Smart packages offer properties that meet the special needs of certain foods. For example, packages made with oxygen-absorbing materials remove oxygen from the inside of the package, thus protecting oxygen-sensitive products from oxidation. Temperature-sensitive films exhibit an abrupt change in gas permeability when they are subjected to a temperature above or below a set constant. These films change from a crystalline structure to an amorphous structure at a set temperature, causing the gas permeability to change substantially.

STORAGE

Food storage is an important component of food preservation. Many reactions that may deteriorate the quality of a food product occur during storage. The nutrient content of foods may be adversely affected by improper storage. For example, a significant amount of vitamin C and thiamine may be lost from foods during storage. Other undesirable quality changes that may occur during storage include changes in colour, development of off-flavours, and loss of texture. A properly designed food storage system allows fresh or processed foods to be stored for extended duration while maintaining quality.

The most important storage parameter is temperature. Most foods benefit from storage at a constant, low temperature where the rates of most reactions decrease and quality losses are minimized. In addition, foods containing high concentrations of water must be stored in high-humidity environments in order to prevent the excessive loss of moisture.

Careful control of atmospheric gases, such as oxygen, carbon dioxide, and ethylene, is important in extending the storage life of many products. For example, in the United States and Canada the apple industry utilizes controlled-atmosphere storage facilities in order to preserve the quality of the fruit. Use of controlled atmospheres to increase the shelf life of fruits was first shown in 1819 by Jacques-Étienne Berard, a professor at the School of Pharmacy at Montpellier, Fr. The commercial development of this technique occurred more than 100 years later with the pioneering work of Franklin Kidd and Cyril West at the Low Temperature Research Station at Cambridge, Eng.

Cereals and other starch products

Cereals, or grains, are members of the grass family cultivated primarily for their starchy seeds (technically, dry fruits), which are used for human food, for livestock feed, and as a source of industrial starch. Wheat, rice, corn (maize), rye, oats, barley, sorghum, and some of the millets are common cereals; their composition is shown in Table 2.

Starch, a carbohydrate stored in most plants, is a major constituent of the average human diet, providing a low-cost energy source with good keeping qualities. Cereals are high in starch, which may be used in pure or flour form. Starches are also obtained from such root sources as potatoes and from the pith of tropical palm trees. Various starches are used commercially in food processing and in the manufacture of laundering preparations, paper, textiles, adhesives, explosives, and cosmetics.

This section treats the processing and utilization of the major cereals—wheat, rice, barley, rye, oats, corn, sorghum, millet, and buckwheat; of important starchy foods consumed in certain countries instead of cereals, including potatoes and cassava; and of soybeans, legumes widely used in the bakery industry. Wheat species are treated in detail, other cereals in a more general way.

CEREAL PROCESSING AND UTILIZATION

Milling. Cereal processing is complex. The principal procedure is milling—that is, the grinding of the grain so that it can be easily cooked and rendered into an attractive foodstuff. Cereals usually are not eaten raw, but different kinds of milling (dry and wet) are employed, depending on the cereal itself and on the eating customs of the consumer. Wheat may be crushed with grinding stones or similar devices or by modern automated systems employing steel cylinders, followed by air purification and numerous sievings to separate the endosperm from the outer coverings and the germ.

Corn is often milled by wet processes, but dry milling is also practiced, especially in the developing countries. Corn, with its high germ content, is inclined to respire more during storage and, unless precautions are taken, may increase in temperature during incorrect storage. Most other cereals are ground in the dry state. Some cereal grains are polished, removing most of the bran and germ and leaving the endosperm.

Uses. *Human food.* Cereals are used for both human and animal food and as an industrial raw material. Although milled white flour is largely used for bread production, especially in industrialized countries, the grain may be converted to food in other ways. In India the major part of the grain is not ground into flour in roller mills but is roughly ground in small crushing mills into a meal called *atta.* This meal is cooked into flat cakes known as chapatis.

Animal food. The principal cereals used as components of animal feeds are wheat and such wheat by-products as the outer coverings separated in the preparation of white flour (bran and the more floury middlings), corn, barley, sorghum, rye, and oats. These are supplemented by protein foods and green fodders.

Animal foods require proper balance between the cereals (carbohydrates) and the more proteinous foods, and they must also contain suitable amounts of necessary minerals, vitamins, and other nutrients. The compounded ration for a milking cow generally contains about 50–80 percent cereals, consisting of wheat by-products, flaked or ground corn, barley, sorghum, wheat, and oats. Requirements for most balanced rations for pigs and poultry are similar. Corn is especially useful in high-energy feeds either as meal or as the flaked and partly gelatinized product; barley is desirable for fattening, and oats help provide a better balanced cereal for livestock. Without cereals for use in farm animal foods, the available supply of the animal protein required in the human diet would be greatly reduced.

Industrial uses. The relatively minor use of cereals in nonfood products includes the cellulose in the straw of cereals by the paper industry, flour for manufacturing sticking pastes and industrial alcohol, and wheat gluten for core binders in the casting of metal. Rice chaff is often used as fuel in Asia.

WHEAT: VARIETIES AND CHARACTERISTICS

The three principal types of wheat used in modern food production are *Triticum vulgare* (or *aestivum*), *T. durum*, and *T. compactum*. *T. vulgare* provides the bulk of the wheat used to produce flour for bread making and for cakes and biscuits (cookies). It can be grown under a wide range of climatic conditions and soils. Although the yield varies with climate and other factors, it is cultivated from the southernmost regions of America almost to the Arctic and at elevations from sea level to over 10,000 feet. *T. durum*, longer and narrower in shape than *T. vulgare*, is mainly ground into semolina (purified middlings) instead of flour. Durum semolina is generally the best type for the production of pasta foods. *T. compactum* is more suitable for confectionery and biscuits than for other purposes.

Wheat grain composition

The wheat grain, the raw material of flour production and the seed planted to produce new plants, consists of three major portions: (1) the embryo or germ (including its sheaf, the scutellum) that produces the new plant, (2) the starchy endosperm, which serves as food for the germinating seed and forms the raw material of flour manufacture, and (3) various covering layers protecting the grain. (See Figure 3.) Although proportions vary, other cereal grains follow the same general pattern. Average wheat grain composition is approximately 85 percent endosperm, 13 percent husk, and 2 percent embryo.

Characteristic variations of the different types of wheat are important agricultural considerations. Hard wheats include the strong wheats of Canada (Manitoba) and the similar hard red spring (HRS) wheats of the United States. They yield excellent bread-making flour because of their high quantity of protein (approximately 12–15 percent), mainly in the form of gluten. Soft wheats, the major wheats grown in the United Kingdom, most of Europe, and Australia, result in flour producing less attractive bread than that achieved from strong wheats. The loaves are generally smaller, and the crumb has a less pleasing structure. Soft wheats, however, possess excellent characteristics for the production of flour used in cake and biscuit manufacture.

Wheats intermediate in character include the hard red winter (HRW) wheats of the central United States and wheat from Argentina. There are important differences between spring and winter varieties. Spring wheats, planted in the early spring, grow quickly and are normally harvested in late summer or early autumn. Winter wheats are planted in the autumn and harvested in late spring or early summer. Both spring and winter wheats are grown in different regions of the United States and Russia. Winter varieties can be grown only where the winters are sufficiently mild. Where winters are severe, as in Canada, spring types are usually cultivated, and the preferred varieties mature early, allowing harvesting before frost.

Strong and weak flour

In baking and confectionery, the terms strong and weak indicate flour from hard and soft wheats, respectively. The term strength is used to describe the type of flour, strong flours being preferred for bread manufacture and weak flours for cakes and biscuits. Strong flours are high in protein content, and their gluten has a pleasing elasticity; weak flours are low in protein, and their weak, flowy gluten produces a soft, flowy dough. (See Figure 5.)

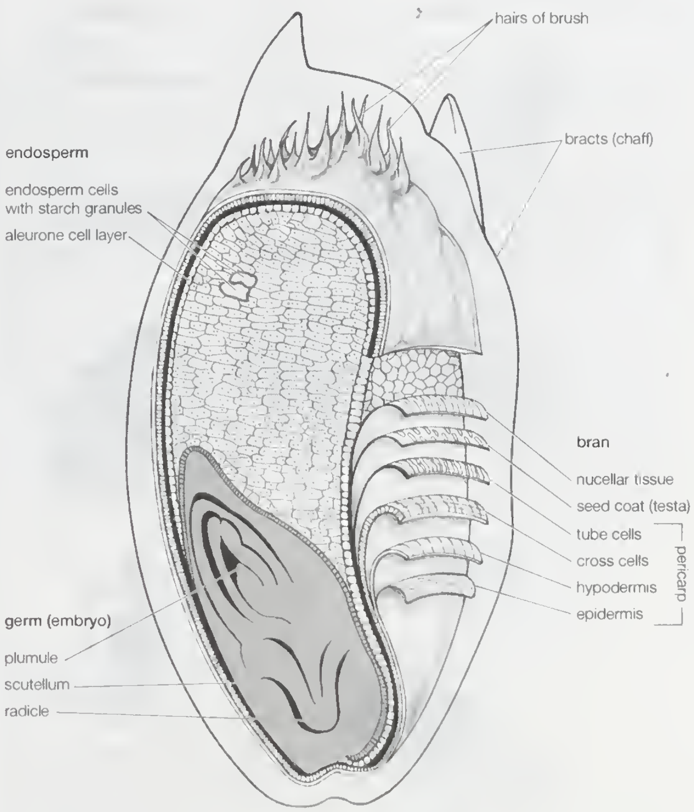

Figure 3: The outer layers and internal structures of a kernel of wheat.
Encyclopædia Britannica Inc

Wheat breeders regularly produce new varieties, not only to combat disease but also to satisfy changing market demands. Many varieties of wheat do not retain their popularity, and often those popular in one decade are replaced in the next. New varieties of barley have also been developed, but there have been few varieties of rice.

WHEAT FLOUR

The milling of wheat into flour for the production of bread, cakes, biscuits, and other edible products is a huge industry. Cereal grains are complex, consisting of many distinctive parts. The objective of milling is separation of the floury edible endosperm from the various branny outer coverings and elimination of the germ, or embryo. Because wheats vary in chemical composition, flour composition also varies.

Although some important changes have occurred in flour milling, basic milling procedure during the past 100 years has employed the gradual reduction process as described below and illustrated in Figure 4.

Milling. In modern milling considerable attention is given to preliminary screening and cleaning of the wheat or blend of wheats to exclude foreign seed and other impurities. The wheat is dampened and washed if it is too dry for subsequent efficient grinding, or if it is too damp it is gently dried to avoid damaging the physical state of the protein present, mainly in the form of the elastic substance gluten.

Gradual reduction from grain to flour

The first step in grinding for the gradual reduction process is performed between steel cylinders, with grooved surfaces, working at differential speeds. The wheat is directed between the first "break," or set of rolls, and is partially torn open. There is little actual grinding at this stage. The "chop," the resulting product leaving the rolls, is sieved, and three main separations are made: some of the endosperm, reduced to flour called "first break flour"; a fair amount of the coarse nodules of floury substances from the endosperm, called semolina; and relatively large pieces of the grain with much of the endosperm still adhering to the branny outsides. These largish portions of the wheat are fed to the second break roll. The broad

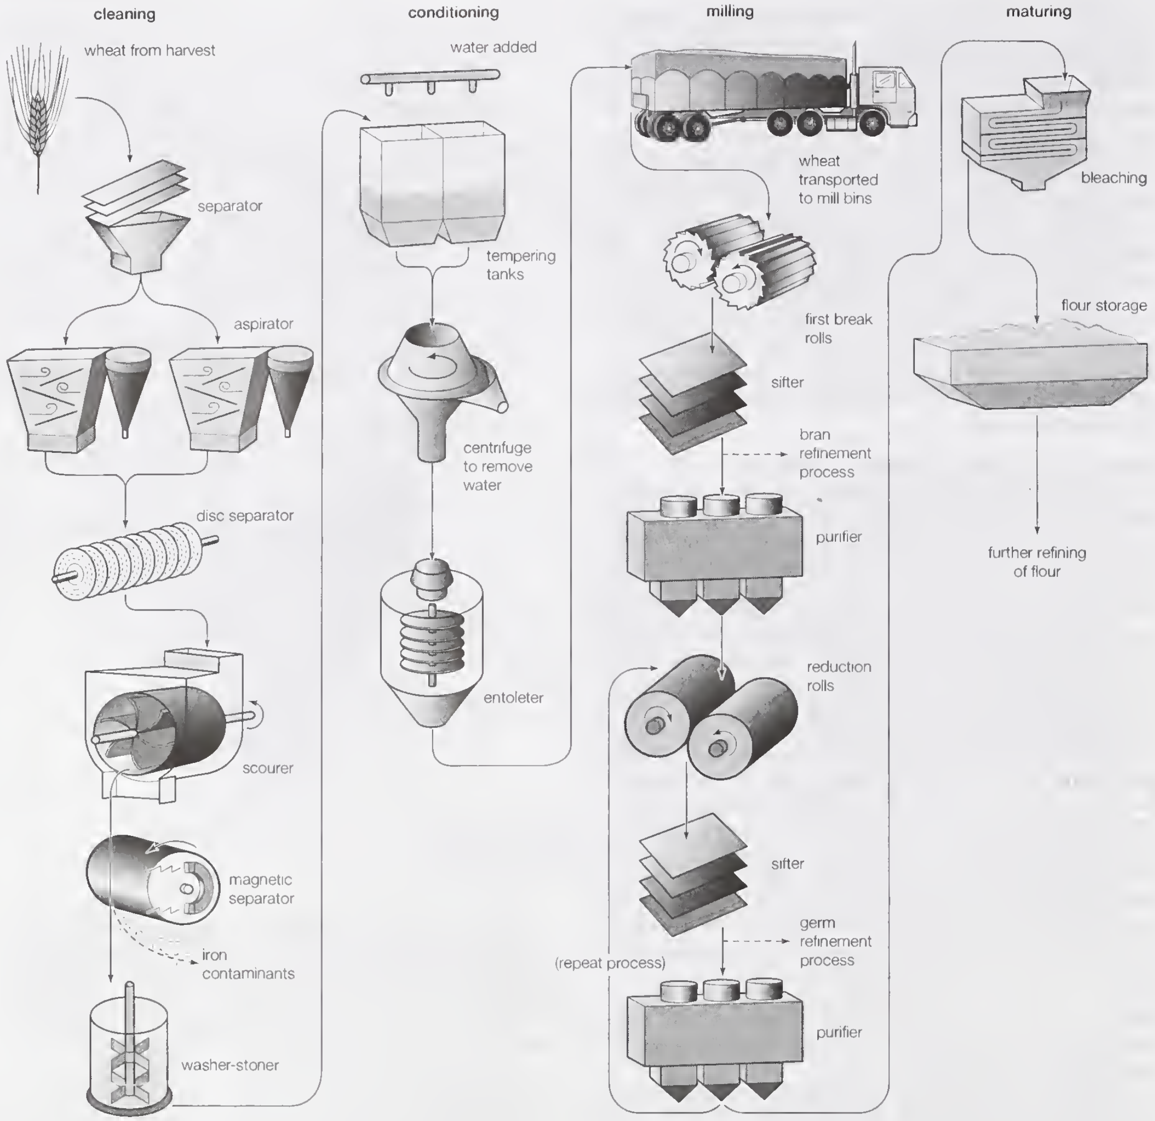

Figure 4: Stages in the milling of wheat into flour.
Encyclopædia Britannica, Inc.

objective of this gradual reduction process is the release, by means of the various sets of break rolls, of inner endosperm of the grain, in the form of semolina, in amounts sufficient that the various semolinas from four or five break rolls can be separated by suitable sieving and the branny impurities can be removed by air purifiers and other devices. The cleaned semolinas are reduced to fine flour by grinding between smooth steel rolls, called reduction rolls. The flour produced in the reduction rolls is then sieved out. There are usually four or five more reduction rolls and some "scratch" rolls to scrape the last particles of flour from branny stocks. Since the various sieving and purification processes free more and more endosperm in the form of flour, flour is obtained from a whole series of processing operations. The flour is sieved out after each reduction roll, but no attempt is made to reduce to flour all the semolina going to a particular reduction roll. Some of the endosperm remains in the form of finer semolina and is again fed to another reduction roll. Each reduction roll tends to reduce more of the semolina to flour and to flatten bran particles and thus facilitate the sieving out of the branny fractions. The sieving plant generally employs machines called plan-sifters, and the air purifiers also produce a whole series of floury stocks.

Modern flour processing consists of a complicated series of rolls, sieves, and purifiers. Approximately 72 percent of the grain finally enters the flour sack.

The sacked flour may consist of 20 or more streams of flour of various states of purity and freedom from branny specks. By selection of the various flour streams it is possible to make flour of various grades. Improvements in milling techniques, use of newer types of grinding machinery in the milling system, speeding up of rolls, and improved skills have all resulted in flour produced by employing the fundamentals of the gradual reduction process but with simplified and shorter milling systems. Much less roll surface is now required than was needed as recently as the 1940s.

Patent flour

The purest flour, selected from the purest flour streams released in the mill, is often called patent flour. It has very low mineral (or ash) content and is remarkably free from traces of branny specks and other impurities. The bulk of the approximately 72 percent released is suited to most bread-making purposes, but special varieties are needed for some confectionery purposes. These varieties may have to be especially fine for production of specialized cakes, called high-ratio cakes, that are especially light and have good keeping qualities.

In many countries the flour for bread production is submitted to chemical treatments to improve the baking quality.

In modern processing, regrinding of the flour and subsequent separation into divisions by air treatment has enabled the processors to manufacture flour of varying protein content from any one wheat or grist of wheats.

Composition and grade. Flour consists of moisture, proteins (mainly in gluten form), a small proportion of fat or lipids, carbohydrates (mainly starch, with a small amount of sugar), a trace of fibre, mineral matter (higher amounts in whole meal), and various vitamins. Composition varies among the types of flour, semolinas, middlings, and bran (see Figure 5).

Gluten

Protein content. For bread making it is usually advantageous to have the highest protein content possible (depending on the nature of the wheat used), but for most other baked products, such as cookies (sweet biscuits) and cakes, high protein content is rarely required. Gluten can easily be washed out of flour by allowing a dough made of the flour and water to stand in water a short time, followed by careful washing of the dough in a gentle stream of water, removing the starch and leaving the gluten. For good bread-making characteristics, the gluten should be semi-elastic, not too stiff and unyielding but not soft and flowy, although a flowy quality is required for biscuit manufacture.

The gluten, always containing a small amount of adhering starch, is essentially hydrated protein. With careful drying it will retain its elasticity when again mixed with water and can be used to increase the protein content of specialized high-protein breads.

Sometimes locally grown wheat, often low in protein, may be the only type available for flour for bread making. This situation exists in parts of France, Australia, and South Africa. The use of modern procedures and adjustment of baking techniques, however, allow production of satisfactory bread. In the United Kingdom, millers prefer a blend of wheat, much of it imported, but modern baking procedures have allowed incorporation of a larger proportion of the weak English wheat than was previously feasible.

Treatment of flour. Use of "improvers," or oxidizing substances, enhances the baking quality of flour, allowing production of better and larger loaves. Relatively small amounts are required, generally a few parts per million. Although such improvers and the bleaching agents used to rectify excessive yellowness in flour are permitted in most countries, the processes are not universal. Improvers include bromates, chlorine dioxide (in gaseous form), and azodicarbonamide. The most popular bleacher used is benzoyl peroxide.

Grade. The grade of flour is based on freedom from branny particles. Chemical testing methods are employed to check general quality and particularly grade and purity. Since the ash (mineral content) of the pure branny coverings of the wheat grain is much greater than that of the pure endosperm, considerable emphasis is placed on use of the ash test to determine grade. Bakers will generally pay higher prices for pure flour of low ash content, as the flour is brighter and lighter in colour. Darker flours may have ash content of 0.7 to 0.8 percent or higher.

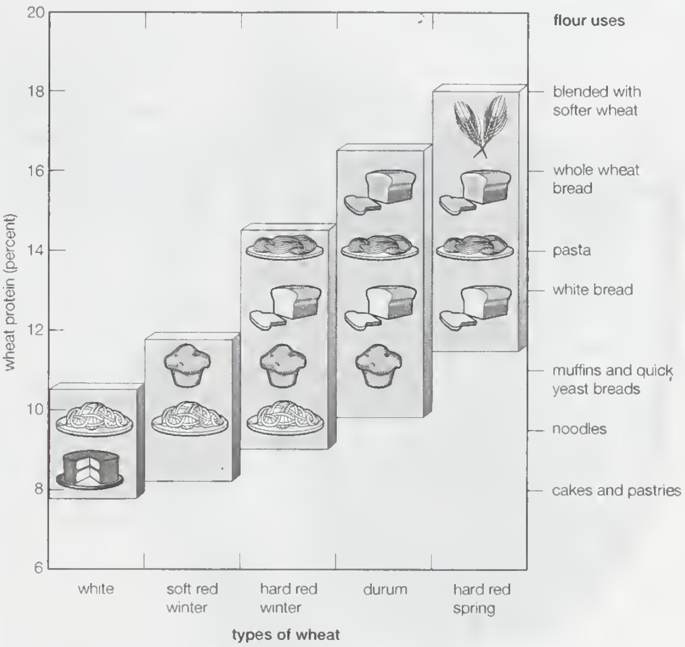

Figure 5: The protein content and major food uses of certain varieties of wheat.

Source: W.G. Heid, *U.S. Wheat Industry*, Agricultural Economics Report, No. 432, U.S. Department of Agricultural Economics, Statistics and Cooperative Service

A widely employed modern method for testing flour colour is based on the reflectance of light from the flour in paste form. This method requires less than a minute; the indirect ash test requires approximately one to two hours.

NONWHEAT CEREALS

Barley. Most of the barley grown in the world is used for animal feed, but a special pure barley is the source of malt for beer production. Barley is also used in the manufacture of vinegar, malt extract, some milk-type beverages, and certain breakfast foods. In addition, in flaked form it is employed in some sections of the brewing industry, and pearl barley (skins removed by emery friction) is used in various cooked foods.

Barley (see Figure 6) can be cultivated on poorer soil and at lower temperatures than wheat. An important characteristic in barley is "winterhardiness," which involves the ability to modify or withstand many types of stresses, particularly that of frost. However, barley is subject to many of the diseases and pests that affect wheat.

The use of barley in animal feed is increasing; it has been a basic ingredient of pig foods for years and is increasingly used for cattle feed. Its use in poultry foods has decreased because it has a lower starch equivalent when compared with wheat or corn and thus provides a lower-energy ration, unsuitable in modern poultry production. Barley vitamin content is similar to that of wheat.

Flint and dent corn

Corn. Corn, or maize, a cereal cultivated in most warm areas of the world, has many varieties. The United States, the principal producer of corn, cultivates two main commercial types, *Zea indurata* (flint corn) and *Z. indentata* (dent corn). The plant grows to a height of about three metres or more. The corn kernel (shown in Figure 7) is large for a cereal, with a high embryo content, and corn oil extracted from the germ is commercially valuable. The microscopic appearance of the starch is distinctive, and the principal protein in ordinary corn is the prolamin zein, constituting half of the total protein. On hydrolysis zein yields only very small amounts of tryptophan or lysine, making it low in biological value. The proteins of corn, like those of most cereals other than wheat, do not provide an elastic gluten.

Much of the corn is wet-processed to produce corn flour, widely used in cooking (see below *Starch products: Cornstarch*). Corn, dry-milled as grits or as meal or turned into flaked corn with some of its starch partially gelatinized, is a popular component in compounded animal feedstuffs. In dry-milled form it is also the basis of human food throughout large areas of Africa and South America. Its

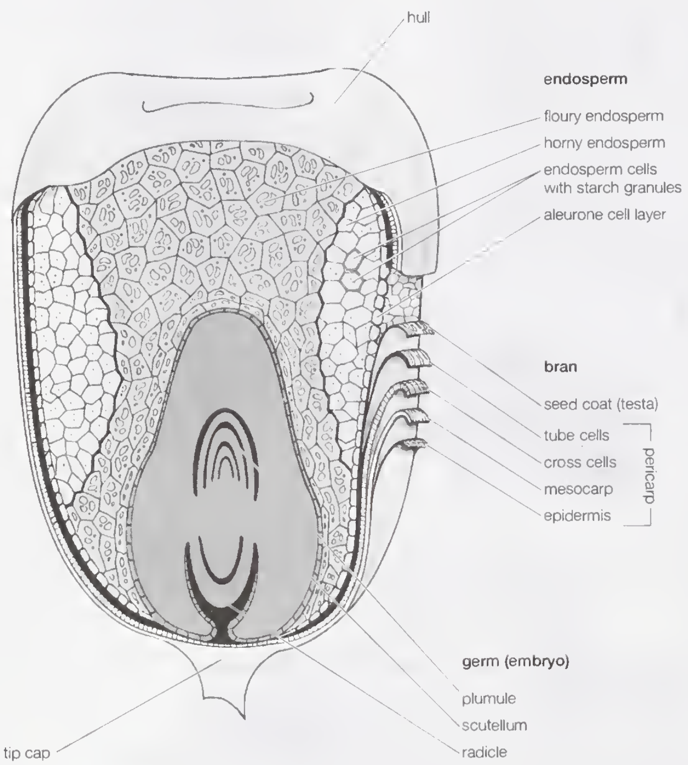

Figure 7: The outer layers and internal structures of a kernel of corn.
Encyclopædia Britannica, Inc.

nutritive value is limited by its low lysine content. Much recent research has involved development of a corn with higher lysine content. Mutants have been produced containing much less zein but possessing protein with higher than normal lysine and tryptophan contents, sometimes increased as high as 50 percent. These corns, called Opaque-2 and Floury-2, possess certain drawbacks. They are generally lower in yield than dent hybrids, are subject to more kernel damage when combine-harvested, and may be more difficult to process. Nevertheless, these new hybrid corns are expected to become widely cultivated, and the principles involved in their production may also be applied to sorghum, wheat, and rice. Corn is popular for use in breakfast foods.

Sorghum. Sorghum, also called milo, is of smaller size than corn but is generally the same type of cereal, with similar appearance. Its numerous types are mainly used for animal feeding. It is grown extensively in the United States, Pakistan, central India, Africa, and China. In the sorghum endosperm, the proteins soluble in hot 60 percent alcohol, called kafirin, constitute the major portion of the protein. Milo germ oil is similar to corn germ oil; its major fatty acids are palmitic, stearic, and particularly oleic and linoleic. Milo is commercially graded in the United States. In waxy varieties the starch is principally in the form of amylopectin, with very little amylose. Such starches possess special viscosity characteristics.

Oats. Oats belong to the botanical genus *Avena,* which includes a large number of types, the principal being *A. sativa, A. sterilis,* and *A. strigosa.* Oats are widely grown in most countries but are not suitable for Mediterranean climates. Oats are frequently grown on farms as feed for the farm's livestock. They are well balanced chemically, with fairly high fat content, and are particularly suitable for feeding horses and sheep.

Although a large portion of the world's oat production is used for animal feed, oatmeal is a popular human food in many countries. Thin-skinned grains, fairly rich in protein and not too starchy, are selected (see Figure 8). Preliminary cleaning is essential for human consumption. The oats are then kilned (roasted). Thin-husked oats yield 60 percent oatmeal; varieties with thick husks yield only 50 percent.

Rapid development of rancidity is a serious problem in oats and oat products. The free fatty acid content must be controlled because formation of these acids tends to produce a soapy taste resulting from the activity of the enzyme lipase. A few minutes of steam treatment normally destroys the lipase activity in the grain.

Rye. Rye, which has been known for some 2,000 years, ranks second to wheat as a bread flour. The principal rye producers are Russia, Poland, Belarus, Germany, and Ukraine. The popularity of true rye bread is decreasing, and a similar bread, retaining some of the original characteristics, is now made from a rye and wheat blend. The protein of European rye tends to be low and does not yield gluten in the same way as does wheat. Rye bread, closer-grained and heavier than wheat bread, is aerated by the use of a leaven (sourdough) rather than yeast. The grain is susceptible to attack by the parasitic fungus ergot (*Claviceps purpurea*).

Rice. Cultivated rice is known botanically as *Oryza sativa,* only one of some 25 species comprising the genus *Oryza*. The importance of this cereal to certain parts of the world may be seen from the fact that in Sanskrit there exists, besides the usual word for rice, another term signifying "sustainer of the human race." Rice is the staple food for millions in Southeast Asia, almost equal to wheat in importance among the world's cereal crops.

Rice as a staple food

Cultivation. More than 90 percent of the world's rice is grown in Asia, principally in China, India, Indonesia, and Bangladesh, with smaller amounts grown in Japan, Pakistan, and various Southeast Asian nations. Rice is also cultivated in parts of Europe, in North and South America, and in Australia. The bulk of the rice cultivated in Asia is grown under water in flooded fields. Successful production depends on adequate irrigation, including construction of dams and waterwheels, and on the quality of the soil. Long periods of sunshine are essential. Rice yields vary considerably, ranging from 700 to 4,000 kilograms per hectare (600 to 3,500 pounds per acre). Adequate irrigation, which means inundation of the fields to a depth of several inches during the greater part of the growing season, is a basic requirement for productive land use.

Dryland paddy production, with harvesting by modern mechanical means, is limited to a few areas, and it produces only a fraction of the total world crop.

As with other cereals, weeds, especially wild red rice, are a constant problem. The commonest pests include plant bugs, stem borers, worms, and grasshoppers. The crop, often harvested with a sickle, is frequently dried in earth or concrete pits. Threshing is often carried out by trampling or with crude implements. Only in a few rice-growing

Encyclopædia Britannica, Inc.

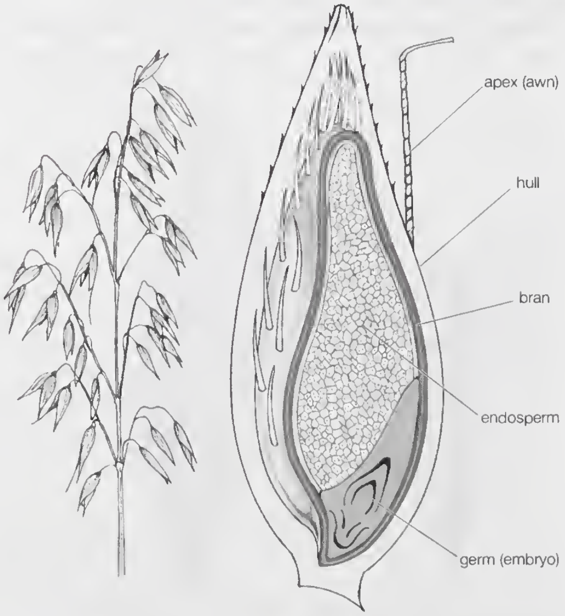

Figure 8: (Left) The oat panicle, bearing multiple oat florets. (Right) Cross section of the oat grain.

regions are more modern procedures used in harvesting.

Manpower requirements for crops vary enormously, but over 400 man-hours per acre are required in smallholdings in Asia, where labour is cheap.

In Asia the paddy is cultivated in three main types of soil, including clays with a firm bottom within a few inches of the surface; silts and soft clays with soft bottoms becoming hard on drying; and peats and "mucks" containing peat, provided the depth of the peat is not excessive. Fields must be drained and dried before harvesting. When combine harvesters or binder threshers are employed, the grain must be dried to about 14 percent moisture so that no deterioration takes place in storage. When reaper binders are used, the crop is "shocked" in certain ways so that the grain is protected from rain.

Milling. Milling methods used in most of Asia are primitive, but large mills operate in Japan and some other areas. Hulling of the paddy is usually accomplished by pestle and mortar worked by hand, foot, or water power. Improvements are slowly taking place. The yield of milled rice is dependent on the size and shape of the grain, the degree of ripeness, and the extent of exposure to the sun. Some large mills, handling 500 to 1,000 tons of paddy daily, have specialized hulling plants with consequent smaller losses from broken grain. They generally employ modern milling techniques and rely on controlled drying plants instead of on sun drying.

Yield of the rice grain

The weight of the husk is about 20 percent of the weight of the paddy, and there are losses of about 5 percent from dirt, dead grains, and other impurities. Approximately 74 percent of the paddy is available as rice and rice byproducts. The yield from milling and subsequent emery polishings includes about 50 percent whole rice, 17 percent broken rice, 10 percent bran, and 3 percent meal. Rice grains have a series of thin coats that can be removed or partially removed in the process of pearling and whitening (see Figure 9).

About 60 percent of the Indian rice is parboiled. In the parboiling process the paddy is steeped in hot water, subjected to low-pressure steam heating, then dried and milled as usual. Parboiling makes more rice available from the paddy, and more nutrients (largely vitamin B_1) are transferred from the outer coverings to the endosperm, improving the nutritive value of the finished product. Parboiled rice may contain two to four times as much thiamine (vitamin B_1) and niacin as milled raw rice, and losses in cooking may also be reduced.

Alcoholic drinks, such as sake in Japan and *wang-tsin* in China, are made from rice with the aid of fungi. The hull or husk of paddy, of little value as animal feed because of a high silicon content that is harmful to digestive and respiratory organs, is used mainly as fuel.

Nutritive value. The lysine content of rice is low. As rice is not a complete food, and the majority of Asians live largely on rice, it is important that loss of nutrients in processing and cooking should be minimal. Lightly milled rice has about 0.7 milligram of vitamin B_1 per 1,000 nonfatty calories, and the more costly highly milled product has only 0.18 milligram of B_1 on the same basis. For adequate nutrition, vitamin B_1 in the daily diet on this basis should be 0.5–0.6 milligram. The amount of fat-soluble vitamins in rice is negligible.

In some countries rice is enriched by addition of synthetic vitamins. According to U.S. standards for enriched rice, each pound must contain 2–4 milligrams of thiamine, 1.2–2.4 milligrams of riboflavin, 16–32 milligrams of niacin, and 13–26 milligrams of iron. In enriched rice the loss of water-soluble vitamins in cooking is much reduced because enrichment is applied to about 1 grain in 200, and these enriched grains are protected by a collodion covering. In ordinary rice, especially when open cookers are employed or excessive water is used, nutrient losses can be high.

Millet. This term is applied to a variety of small seeds originally cultivated by the ancient Egyptians, Greeks, and Romans and still part of the human diet in China, Japan, and India, though in Western countries it is used mainly for birdseed. The genus is termed *Panicum.* The small seed is normally about two millimetres long and nearly two millimetres broad. The term *proso* is one of several alternative names. Japanese barnyard millet is a well-known variety.

Encyclopædia Britannica, Inc

OTHER STARCH-YIELDING PLANTS

Cassava. Cassava, often called manioc, is not a cereal but a tuber; however, it replaces cereals in certain countries, supplying the carbohydrate content of the diet. The botanical name is *Manihot esculenta,* and the plant is native to South America, especially Brazil. It is now grown in Indonesia, Malaysia, the Philippines, Thailand, and parts of Africa. A valuable source of starch, cassava is familiar in many developed countries in a granular form known as tapioca.

Tapioca

Easily cultivated and curiously immune to most food-crop pests, cassava is a staple crop in several areas of Latin America. The actual tubers may weigh up to 14 kilograms (30 pounds). Some tubers may be bitter and contain dangerously large amounts of prussic acid.

Dry milling of cassava is rarely practiced because it yields a product inferior to wet-processed starch in which the tubers are crushed or rasped with water and the starch is permitted to settle. Wet starch is dried to a point where it can be crumbled by pressing it through metal plates (or sieves). This crumbled material is subjected to a rotary motion, sometimes carried out on canvas cloth fastened to cradle-shaped frames. Another method is to tumble the material in revolving steam-jacketed cylinders so that the particles assume a round pellet form and are partially gelatinized as they dry. Sun drying is employed in both homes and small mills.

Many tapioca factories and mills are equipped with modern raspers, special shaking or rotating sieves, and settling tanks of various types; but some fermentation takes place, and small rural mills can often be identified by the smell of butyric acid. In larger mills, centrifuges are replacing the settling tanks.

For its various industrial uses, the tuber usually goes under its alternative name, manioc. It is used in the textile industries, explosives manufacture, leather tanning, and production of glues and dextrins and alcohol.

Fresh cassava leaves are rich in protein, calcium, and vitamins A and C. Their prussic acid level must be reduced to safe limits by boiling; the duration of boiling depends on the variety of the leaves. Cassava leaves are a popular vegetable in Africa, and the tuber also is used in meal for animal feed.

Soybean. Soybean (*Glycine max*) is not a cereal but a legume; because of its widespread use in the baking industry, it may appropriately be dealt with here. Soybean provides protein of high biological value. Although Asia is its original source, the United States became the major world producer in the late 20th century.

The valuable oil of the soybean, widely used in industry, is extracted either by solvents or by expellers. The amino acid distribution of soy protein is more like that found in animal protein than the protein from most vegetable sources; for example, lysine comprises about 5.4 percent. The oil content includes useful amounts of phosphorus; the phosphatide content of soy flour is about 2 percent and is a mixture of lecithin and cephalin. The low carbohydrate content exists mainly as sugars. Table 3 shows the amino acid composition of soy protein.

Table 3: Amino Acid Composition of Soy Protein
(calculated to 16 percent nitrogen)

	percent
Arginine	5.8
Histidine	2.3
Lysine	5.4
Tyrosine	4.1
Tryptophan	1.2
Phenylalanine	5.7
Cystine	0.9
Methionine	2.0
Threonine	4.0
Leucine	6.6
Isoleucine	4.7
Valine	4.2
Glutamic acid	21.0
Aspartic acid	8.8

Although soybeans are a good source of thiamine, much of this may be lost in processing. Average vitamin contents of soybean (as micrograms per gram) are as follows: thiamine 12, riboflavin 3.5, nicotinic acid 23, pyridoxine 8, pantothenic acid 15, and biotin 0.7.

The bulk of the soybean produced in the United States is used for animal feed; the Asian crop goes principally for human diet.

Soybean milk

Soybean milk is produced and used in the fresh state in China and as a condensed milk in Japan. In both of these preparations, certain antinutritive factors (antitrypsin and soyin) are largely removed. In the Western world most soy products are treated chemically or by heat to remove these antinutritive factors along with the unpopular beany taste. Such processing affects the enzymatic activity in the milk.

Soybean is milled to produce soy flour. The flour is often used in a proportion of less than 1 percent in bakery operations. It stiffens doughs and helps to maintain crumb softness. Unprocessed soy flour, because of its lipoxidase enzyme system, is employed with high-speed mixing to bleach the flour in a dough.

In addition to their use in bread, soy products are used in confectionery, biscuits, macaroni, infant and invalid foods, ice cream, chocolate, sausages, sauces, lemon curd, mayonnaise, meat and fish pastes, certain diabetic foods, and in such nonfood products as paint, paper, textiles, and plastics.

A recent development is the isolation of the soybean proteins for use as emulsifiers and binders in meat products and substitutes. Enzyme-modified proteins provide useful egg-albumen supplement for whipped products.

Buckwheat. Botanically, buckwheat is not a cereal but the fruit of *Fagopyrum esculentum*. Its name is probably derived from its resemblance to beechnut. Believed to have originated in China, the plant grows to a height of about one metre and thrives best in cool, moist climates, although it does not easily tolerate frost. It can be grown on a wide range of soils, and a crop can be obtained within 10–12 weeks of sowing. The seed is dark brown in colour and often triangular in shape. It contains about 60 percent carbohydrate, 10 percent protein, and 15 percent fibre. A white flour can be obtained from the seeds (buckwheat cakes and pancakes are popular in certain areas), and buckwheat meal is also used in animal feed. The whole seed may be fed to poultry and game birds. There is some medical interest in buckwheat as a source of rutin, possibly effective in treatment of increased capillary fragility associated with hypertension in humans.

STARCH PRODUCTS

Commercial starches. Starch has been used for many centuries. An Egyptian papyrus paper dating from 3500 BC was apparently treated with a starch adhesive. The major starch sources are tubers, such as potatoes and cassava, and cereals. Current starch production is considerable. Among the major producing areas, the European countries use both domestic wheat and potatoes and imported corn as the raw material; the United States uses corn and such similar cereals as sorghum; and in South America the cassava plant is the major raw material.

Separated from tubers and cereals, starch is used for conversion into various sugars, and half of the world's separated starch is processed into glucose. Starch is also processed for use in adhesives manufacture. In the food industry starch is used as a thickener in the preparation of cornstarch puddings, custards, sauces, cream soups, and gravies. Starch from tubers and cereals provides the carbohydrate of the human diet.

Large quantities of starch and its derivatives are used in the paper and textile industries.

Potato farina

Starch from tubers. In Germany, The Netherlands, Poland, and a number of other countries, the extraction of the starch from potatoes (sometimes called farina) is a major industry. Some factories produce over 300 tons daily. Processing involves continuous and automatic cleaning of the potatoes, thorough disintegration in raspers or hammer mills, and separation of the fibres from the pulp by centrifugal (rotary) sieves. The resulting starch "milk" contains starch in suspension and soluble potato solids in solution. The starch is separated and washed free from the solubles, the water is removed by centrifugal action, and the damp starch is dried. The flash type of dryer, using hot air, is widely employed for starches derived from both tubers and cereals. Sulfurous acid is generally introduced into the process to prevent the development of various microorganisms.

Potato flour is also produced in Germany and other countries, slices of cleaned potatoes being dried, ground, and sieved. In Germany a "potato sago" is produced. The starch cake obtained from the potatoes is crumbled to produce reasonably uniform-size particles that are rounded by tumbling or similar operations, heated to gelatinize the outside layers of the starch, and then dried.

Potatoes were employed in baking to make the barm, or leaven, before compressed distiller's yeast was available, and they have also been used to supplement limited supplies of wheat flour. The potatoes are cleaned, boiled until soft but not mushy, and mixed, in a proportion of 2 to 3 percent, in the dough.

Modern, ready-to-use, dried and powdered mashed potatoes are popular consumer products.

Cassava and tapioca starches are sometimes partially gelatinized by vacuum drying. Protein impurities are low in commercial starches of potato, sago, and tapioca but as high as 0.2 percent in wheat starch and higher in corn flour.

Corn flour

Cornstarch. Corn is wet-milled to produce corn flour, or cornstarch, desirable for cooking because it forms a paste that sets with a "short" texture and separates from molds more cleanly than do the gels produced by such starches as potato, tapioca, and arrowroot, which are "long," or elastic. In wet milling, the grains are first dry-cleaned so that other cereals and some of the impurities are removed, then steeped in warm water containing sulfur dioxide. This process softens the grains, and the outer skin and the germ are rendered removable. The corn is coarsely ground in "degerminating mills," and the slurry is further wet-ground and sieved to remove all the germ and complete the separation of the starch.

The germ, rich in oil, is eventually dried, and the oil is expelled by pressure, providing an excellent edible oil for culinary use, often replacing olive oil. Corn oil is used for salad oil, margarine, and shortening and for such nonfood items as soap.

The pure starch, held in suspension, was formerly collected by gravity as it flowed down tables, but in modern practice the starch suspension is thickened by the elimination of water by means of machines, and the starch is finally separated by the use of centrifuges. The starch is readily dried without gelatinization taking place.

There is a regular demand for a good grade of corn flour, or cornstarch. Roller-milled corn is still produced for human consumption in Africa and elsewhere. In the United States some corn grits are used by brewers, but the bulk of the corn grown is used for animal feed as meal, grits, or in partially gelatinized flake form.

Rice starch. Rice starch, largely used in laundry work, is normally prepared from broken white rice. The broken grains are steeped for several hours in a caustic soda solution, and the alkali is finally washed away with water. The softened grains are ground with more caustic soda solution, and the resulting mass is settled or submitted to centrifugation in a drum. The starch layer is agitated with water (often with 0.25 percent formaldehyde solution added), and the resulting starch liquor is dewatered, washed on a continuous rotary vacuum filter, resuspended in water, and finally dewatered in a perforated basket centrifuge to about 35 percent moisture. In modern processing it is usual to roll out a thick layer of moist starch, which is then slowly dried and falls to pieces as crystals.

Starch composition. Starch consists of two components: amylose and amylopectin. The relative proportion of these two components varies, and they react differently to enzymatic attack. The enzyme β-amylase (maltogenic) attacks the straight chain amylose but is unable to attack most of the branch chain amylopectin. If only β-amylase is present, maltose is produced, together with a residue of the amylopectin portion, or dextrin of high molecular weight. When α-amylase (dextrinogenic) attacks starch, gummy dextrins of low molecular weight are formed and can produce a sticky crumb in bread.

In bread making there is only limited time for such enzymatic attacks on the starch, and only the "attackable" or "damaged" granules can produce the fermentable sugar for the dough. The β-amylase has little effect on viscosity. The viscosity of gelatinized starch is markedly reduced by α-amylase, however, and is therefore valuable in syrup and dextrose manufacture.

The gelatinization of starch that occurs in hot water is an important characteristic, and the viscous pastes formed are influenced by the treatment the starch has received in its preliminary separation from the cereal or tuber. Chemicals affect degree and speed of gelatinization and the nature and viscosity of the pastes formed.

In certain cereals, particularly in special corns, the starch consists almost entirely of amylopectin, and the term "waxy" is applied to such cereals. They are useful for their unusual physical properties and viscosities. They possess outstanding paste clarity, high water-binding capacity, and resistance to gel formation and retrogradation; they are helpful in production of salad dressings, sauces, and pie fillings and in some canned goods; they are useful because of resistance to irreversible gel formation and syneresis on freezing and especially for many products stored in the frozen state.

Processing. The carbohydrate starch is rarely consumed in the raw state and in cooking is always gelatinized to some degree. For industrial purposes starches are submitted to many processes. Starch is often partially or almost wholly gelatinized or may be converted by heat or chemical treatment into dextrins for use in adhesive pastes, with the starch assuming a completely new form. Other treatments increase solubility, and hydrolysis with acids produces completely new products, including a variety of sugars.

Starch may be converted into sugars by the use of acids, and the sugars may be marketed as starch syrup, glucose syrup, or corn syrup; as glucose; and as commercial dextrose. Such sugars are useful in confectionery production.

Other uses of starch include production of ethyl alcohol by fermentation procedures and production of acetone and other products. Indeed, it is impossible to record all the hundreds of uses of starch in the science-based industries.

Alimentary pastes. *Pasta products.* Alimentary pastes include such products as macaroni, spaghetti, vermicelli, and noodles. Such products are often called pastas. Italy is regarded as the place of origin of macaroni products, and annual consumption in that country is as high as 30–35 kilograms (65–75 pounds) per person. Annual consumption is about 6.3 kilograms in France, 3.7 in the United States, and only 0.4 kilogram in the United Kingdom. Pasta is manufactured in a wide variety of sizes and shapes (see Figure 10), the commonest being long, narrow strands. The most slender type of strand, vermicelli, sometimes called *capelli d'angeli* ("angel's hair") in Italy, has a diameter ranging from 0.5 to 0.8 millimetre and is normally cut into lengths of about 250 millimetres and twisted into curls. Short-cut vermicelli (15–40 millimetres) is easy to manufacture and to dry. Spaghetti has a diameter of about 1.5–2.5 millimetres and is usually straight. Noodles are solid ribbons, about 0.8 millimetre thick, and in a variety of widths. Macaroni is the commonest type of alimentary paste; it is hollow and has a greater thickness than the others. It can be shaped in a variety of forms, such as long, short, large, small tubes, etc.

ries in Italy, North and South America, and other regions. Drying of the extruded paste is an important process, previously accomplished in Italy by sun drying.

Semolina. Semolina, not flour, is the form of cereal used, and various plain macaroni products are made by combining the correct form of semolina, from durum wheat, with water. Richer alimentary pastes are made with the addition of eggs in fresh, dried, or frozen form, and egg noodles are popular. In low-income families, alimentary pastes often provide the bulk of the calories in the diet. Macaroni products supply about 3,500 calories per kilogram and, although not themselves good sources of vitamins, are commonly cooked and consumed with butter, oil, cheese, and other items containing the needed vitamins.

The use of hard durum semolina contributes to good quality in macaroni and other alimentary paste products. The special mills involved use many breaks, and only a few reduction rolls, to produce as much clean semolina as possible. An efficient mill employing appropriate purifiers can produce as much as 65 percent semolina (together with a little flour). Before continuous processes for pasta production were introduced, a coarse semolina was valued. In modern production, semolina is dusted and freed from flour, and regularity in size is considered important for water absorption. Very fine semolina is not popular, and the preferred semolina usually has a moisture content of about 13 percent with less than 0.8 percent ash. Freedom from bran is desired to avoid the appearance of specks. The gluten in the semolina should be reasonably strong but not as elastic as that required for bread making. .

Pasta processing. In the early factories, batch mixing of semolina and water was followed by extrusion of the resulting paste through presses containing dies. In modern practice, the bulk of alimentary pastes is made by continuous processes.

Extrusion

The basic procedure for most macaroni products consists of adding water to a semolina made from suitable wheat to produce, in a short time, a plastic homogeneous mass of about 30 percent moisture. This mixture is extruded through special dies, under pressure, producing the desired size and shape, and is then dried (see Figure 11). There are many types of continuous paste processes adapted to the specific types of paste wanted and to the manufacturer's requirements. In the earlier days of the cottage industry, long-cut products such as spaghetti were spread evenly by hand on wooden dowels about an inch thick and over 50 inches long, and the filled sticks were then placed on racks for sun drying. Short-cut products were often scattered on wire mesh trays.

In modern automatic processing the objective is to dry the extruded product, containing 31 percent moisture, to a hard product of about 12 percent moisture, decreasing the possibility of the goods being affected by the growth of molds and yeast. If moisture is removed too rapidly, the dried product may tend to "check" or split. If moisture is removed too slowly, souring or mold growth may occur. Proper drying is therefore ensured by adjusting air circulation, temperature, and humidity. Drying procedures differ for long and short macaroni. In the continuous process, after a first hour in which a crust is formed to protect against mold infection, slow drying is practiced.

Testing. Cooking tests are used to ensure that the final product is satisfactory. Considerable research has been carried out to control factors tending to destroy the desirable yellow colour. Destruction of the colouring matter, a xanthophyll, can occur in mixing owing to excessive lipoxidase. Certain typès of durum wheat may possess a high degree of lipoxidase activity, and it is difficult to control or check this action. The addition of ascorbic acid has been suggested as a means to decrease the destruction of the semolina pigments in processing.

In the United States, alimentary paste goods, described as noodles, egg spaghetti, or egg macaroni, must contain 5.5 percent of the solids of egg in the final product. The eggs can be used in the form of frozen yolks, dried yolks, frozen whole eggs, dried whole eggs, or fresh whole eggs or yolks. Spray-dried egg yolks of good quality are now available.

Kellogg and Post

Breakfast cereals. *Origins.* The modern packaged breakfast-food industry owes its beginnings to an American religious sect, the Seventh-day Adventists, who wished to avoid consumption of animal foods. In the 1860s they organized the Western Health Reform Institute in Battle Creek, Mich., later renamed the Battle Creek Sanitarium. James Jackson of Dansville, N.Y., produced a cereal food by baking whole-meal dough in thin sheets, breaking and regrinding into small chunks, rebaking and regrinding. J.H. Kellogg of Battle Creek made biscuits about one-half inch thick from a dough mixture of wheatmeal, oatmeal, and cornmeal. The dough was baked until it was fairly dry and turning brown, and the product was ground and packed. A patient at the sanitarium, C.W. Post, saw the possibilities in such a product entirely apart from the

Encyclopædia Britannica, Inc.

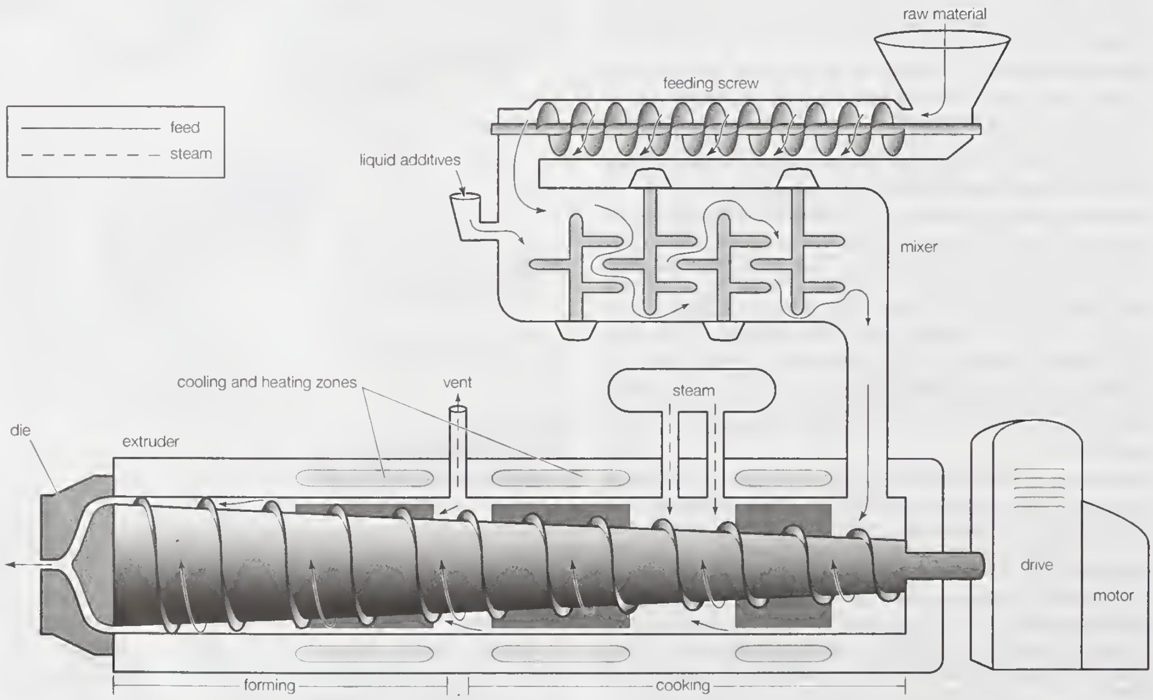

Figure 11: A high-temperature short-time extruder.

original conception of healthfulness and started a business. Kellogg's brother, W.K. Kellogg, did likewise, and the breakfast-food industry was launched, soon achieving mass sales of cereal products in flaked, granular, shredded, and puffed forms, with flavour obtained by roasting and the addition of sugar.

Types of breakfast cereal. Some breakfast cereals require cooking; others are packaged ready-to-eat. Roasted and rolled oatmeal, eaten as porridge, requires brief boiling. Cooking time of these processed cereals has been greatly reduced, and various "instant" forms are available.

Although cooked oatmeal porridge was formerly a standard breakfast food, the ready-to-eat cereals of various types are now the favourite breakfast-cereal foods.

The middlings produced in flour milling, essentially small pieces of endosperm free from bran and germ, are sold as farina and often consumed as a breakfast food in the United States. Farina is usually enriched with vitamins and minerals and may be flavoured. To reduce cooking time, 0.25 percent disodium phosphate may be added; some products require only one minute of boiling before serving.

Ready-to-eat cereals are available in a variety of forms and are normally consumed with milk and sometimes sugar. Flaked and toasted varieties are the most popular. During processing the starch is gelatinized, halting enzymatic reactions and thus ensuring product stability and good shelf life. The sugar content is dextrinized and caramelized by a roasting process. Roasting also ensures attractive crispness resulting from moisture reduction.

Flaked cereals. Wheat and rice flakes are manufactured, but most flaked breakfast foods are made from corn (maize), usually of the yellow type, broken down into grits and cooked under pressure with flavouring syrup consisting of sugar, nondiastatic malt, and other ingredients. Cooking is often accomplished in slowly rotating retorts under steam pressure.

After leaving the cooker, the lumps (containing about 33 percent water) are broken down by revolving reels and sent to driers. These are usually large tubes extending vertically, through several stories, with the wet product entering the top and encountering a current of hot air (65° C, or 150° F). Other types of driers consist of horizontal rotating cylinders with steam-heated pipes running horizontally. The drying process reduces moisture to about 20 percent, and the product is transferred to tempering bins for up to 24 hours, to even moisture distribution.

The product is next flaked by passing it between large steel cylinders (180–200 revolutions per minute), with the rolls cooled by internal water circulation. The cooked and rather soft flakes then proceed to rotating toasting ovens (normally gas-fired), where the flakes tumble through perforated drums. This treatment requires two to three minutes at 225° C (550° F). The product is dehydrated, toasted, and slightly blistered. After toasting it is cooled by circulating air, and at this stage enrichment by sprays may be carried out.

The manufacture of wheat flakes is similar to that of corn flakes. Special machinery separates the individual grains so that they can be flaked and finally toasted.

Shredded cereals. Shredded wheat, differing from other breakfast foods, is made from whole grains with the germ and bran retained and no flavour added. In its final form it is in tablets composed of shreds of cooked and toasted wheat. The wheat is cleaned and then boiled in water, often at atmospheric pressure. The grains reach a moisture content of 55 to 60 percent and require preliminary drying to about 50 percent. They are then placed in bins to condition them. The shredding process consists of passing the cooked and partially dried wheat to the shredding rolls, which are 150 to 200 millimetres (6 to 8 inches) in diameter and as wide as the finished tablet. On one pair of the rolls is a series of about 20 shallow corrugations running around the periphery; the surface of the other roll is smooth. The soft wheat is forced into the rolls under pressure and is cut into long shreds falling to a conveyor in such a way as to obtain superimposed shreds. These layers are cut into tablets by knives, and the tablets are transferred to baking pans. The pans pass to a revolving oven, with a baking temperature of approximately 260° C (500° F). After 10–15 minutes the outside of the product is dry and toasted, while the interior is still damp. The tablet is transferred either to another hot air oven or to a different section of the same oven, where it is dried at 120° C (250° F) for an additional 30 minutes and then cooled and packed.

Granular cereals. Granular types are made by very different processes from the others. The first step is production of a stiff dough from wheat, malted barley flour, salt, dry yeast, and water. After mixing, fermentation proceeds for about five hours. The dough is then formed into large loaves and transferred directly to the oven. Baking requires about two hours at 205° C (400° F). The baked loaves are fragmented and the product is then thoroughly dried. Grinding by corrugated rolls follows, and the product is sieved to standard size. Very finely ground pieces are added to subsequent dough batches.

Puffed cereals. Early in the 20th century an American patent was taken out for the preparation of puffed wheat and rice. Puffed oats and corn are now also produced. The principle of the puffing process is heating the cereal, and sometimes other vegetable products, in a pressure chamber to a pressure of 7 to 14 kilograms per square centimetre (100 to 200 pounds per square inch), then instantaneously releasing this pressure by suddenly opening the chamber, or puffing gun. Expansion of the water vapour occurs when the pressure is suddenly released, blowing up the grains or cereal pellets to several times their original size (8-fold to 16-fold for wheat, 6-fold to 8-fold for rice). The final product is toasted to a moisture content of about 3 percent to achieve desired crispness. In processing wheat, a preliminary step may be applied to free the grain from much of its bran coatings.

The puffing gun

Rice is usually parboiled, pearled, and cooked with sugar syrup, dried to about 25 to 30 percent moisture in rotating louvre dryers, binned, and toasted and puffed. In puffing of mixed cereal products it is necessary to start with a stiff dough containing sugar, salt, and sometimes oil, and this mixture is then cooked. The dough is pelleted by extrusion through dies and dried to attain a suitable condition for the final puffing process.

Enrichment. Enrichment of breakfast cereals with minerals, and especially with vitamins, is now common practice. In many of the manufacturing processes employed in breakfast-food production, considerable vitamin destruction occurs. The various heat treatments involved may destroy 90 percent of the original B_1 content of the cereal, especially in flaked and puffed products. On the other hand, a proportion of the somewhat harmful phytic acid in cereals, interfering with absorption by the body of calcium, is also destroyed; and enrichment of the products with vitamin B_1, and sometimes other components of the vitamin B complex, is not difficult to perform after the various cooking operations have been completed.

Sweeteners. Various types of sweeteners are made directly from starch. Glucose products made by starch conversion differ in composition and in sweetness according to whether conversion is effected by acid or by enzymes. Enzyme-produced glucose is higher in dextrose and maltose content than acid-produced glucose, which normally is higher in dextrin. Sucrose is a more powerful sweetening agent than dextrose, but glucose syrup made by enzymatic treatment usually has twice the sweetening power of that produced by acid action.

Corn syrup

In the production of starch separated by the wet milling of corn, one stream is normally used to produce starch, and the other stream is converted into corn syrup by heating the starch slurry in pressure tanks with acid or enzymes and following with refining processes. If the process of hydrolyzing starch is completed, the resulting product is glucose. Often the treatment is not carried to completion, and a series of dextrins and reversion products is produced. If full conversion is required, the treatment usually employs acids to liquefy, followed by saccharifying enzymes to complete the change to dextrose. Modern syrups and crystalline dextrose are made by continuous processes. The degree of conversion of the starch into the sugar dextrose is expressed as D.E. (dextrose equivalents), and confectionery syrups have a D.E. of about 36 to 55, while the fuller conversion of products with D.E. of 96 to 99 can be made for the production of almost pure glucose or dextrose, used in many food products.

Sweeteners in the form of syrups are largely used in cake and confectionery products and also, especially in the United States, in bread manufacture. American bread is distinctly sweeter than normal European bread because of the fats and sweeteners used, and the loaves are larger per unit of weight than in the United Kingdom and most European countries.

In the United States the baking industry uses more than one-half of the dextrose and 10 percent of the corn syrup produced. Makers of cookies (biscuits) and breakfast foods also use large amounts of sweeteners. Confectioners in Europe use syrups of many types but not as widely as in the United States. (D.W.K.-J./Ed.)

Edible fats and oils

The oil and fat products used for edible purposes can be divided into two distinct classes: liquid oils, such as olive oil, peanut oil, soybean oil, or sunflower oil; and plastic fats, such as lard, shortening, butter, and margarine. The physical nature of the fatty material is unimportant for some uses, but the consistency is a matter of consequence for other products. As a dressing on green salads, for example, a liquid oil is used to provide a coating on the ingredients; a plastic fat such as lard or butter would be unsuitable. Spreads for bread, foods that require a highly developed dough structure, or icings and fillings with a plastic structure require plastic fats rather than liquid oils.

GENERAL METHODS OF EXTRACTION

The raw materials for the fat and oil industry are animal by-products from the slaughter of cattle, hogs, and sheep; fatty fish and marine mammals; a few fleshy fruits (palm and olive); and various oilseeds. Most oilseeds are grown specifically for processing to oils and protein meals, but several important vegetable oils are obtained from by-product raw materials. Cottonseed is a by-product of cotton grown for fibre, and corn oil is obtained from the corn germ that accumulates from the corn-milling industry, whose primary products are corn grits, starch, and syrup.

Fats may be recovered from oil-bearing tissues by three general methods, with varying degrees of mechanical simplicity: (1) rendering, (2) pressing with mechanical presses, and (3) extracting with volatile solvents.

Rendering. *Fruits and seeds.* The crudest method of rendering oil from oleaginous fruits, still practiced in some countries, consists of heaping them in piles, exposing them to the sun, and collecting the oil that exudes. In a somewhat improved form, this process is used in the preparation of palm oil; the fresh palm fruits are boiled in water, and the oil is skimmed from the surface. Such processes can be used only with seeds or fruits (such as olive and palm) that contain large quantities of easily released fatty matter.

Animal fats. The rendering process is applied on a large scale to the production of animal fats such as tallow, lard, bone fat, and whale oil. It consists of cutting or chopping the fatty tissue into small pieces that are boiled in open vats or cooked in steam digesters. The fat, gradually liberated from the cells, floats to the surface of the water, where it is collected by skimming. The membranous matter (greaves) is separated from the aqueous (gluey) phase by pressing in hydraulic or screw presses; additional fat is thereby obtained. The residue is used for animal feed or fertilizer. Several centrifugal separation processes were developed in the 1960s. Cells of the fatty tissues are ruptured in special disintegrators under close temperature control. The protein tissue is separated from the liquid phase in a desludging type of centrifuge, following which a second centrifuge separates the fat from the aqueous protein layer. Compared with conventional rendering, the centrifugal methods provide a higher yield of better-quality fat, and the separated protein has potential as an edible meat product.

Pressing. *Pressing processes.* With many oil-bearing seeds and nuts, rendering will not liberate the oil from the cellular structures in which it is held (see Figure 12). In these cases the cell walls are broken by grinding, flaking, rolling, or pressing under high pressures to liberate the oil. The general sequence of modern operations in pressing oilseeds and nuts is as follows: (1) the seeds are passed over magnetic separators to remove any stray bits of metal; (2) if necessary, the shells or hulls are removed; (3) the kernels or meats are converted to coarse meal by grinding them between grooved rollers or with special types of hammer mills; and (4) they are pressed in hydraulic or screw presses with or without preliminary heating, depending on the type of oil-bearing material and the quality of oil desired. Oil expressed without heating contains the least amount of impurities and is often of edible quality without refining or further processing. Such oils are known as cold-drawn, cold-pressed, or virgin oils. Pressing the coarse meal while it is heated removes more oil and also greater quantities of nonglyceride impurities such as phospholipids, colour bodies, and unsaponifiable matter. Such oil is more highly coloured than cold-pressed oils. Residual meals are concentrated sources of high-quality protein and are generally used in animal feeds.

Quality variations in pressed oils

Encyclopædia Britannica, Inc.

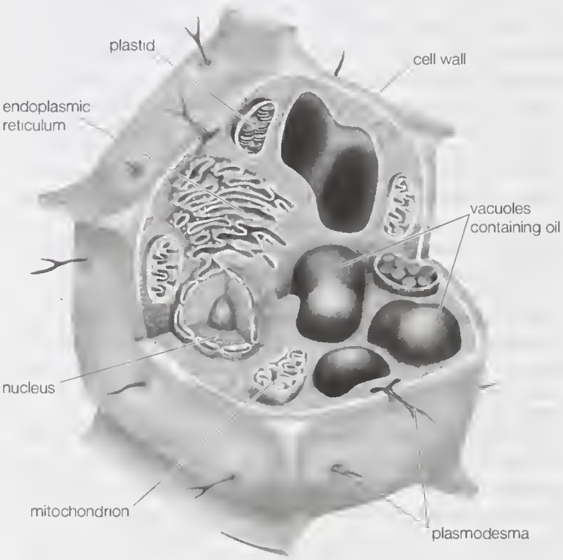

Figure 12: Some of the structures of an oilseed cell, including oil-containing vacuoles.

Pressing machines. Many different mechanical devices have been used for pressing. The Romans developed a screw press, described by Pliny, for the production of olive oil. Centuries ago, the Chinese employed the same series of operations followed in modern pressing mills—namely, bruising or grinding the seeds in stone mills, heating the meal in open pans, and then pressing out the oil in a wedge press. The Dutch, or stamper, press invented in the 17th century was used almost exclusively in Europe for pressing oilseeds until the early part of the 19th century, when the hydraulic press was developed. The yield of oil from the hydraulic press was considerably higher than that from earlier processing methods because of the much higher applied pressures. In open presses, the ground seed material was confined in cloths of human hair or, less commonly, camel hair. Pressures on the cake varied from approximately 70 to 140 kilograms per square centimetre (1,000 to 2,000 pounds per square inch), and in the closed-type press, in which the oil-containing material was confined in a strong perforated steel cage during the pressing operation, pressures of approximately 400 kilograms per square centimetre or more were attained. Under ideal conditions the oil content of the hydraulic-press cake can be reduced to about 3 percent, but in practical operation a 5 percent level is average. The modern screw press replaced many of the hydraulic presses because it is a continuous process, has greater capacity, requires less labour, and will generally remove more oil. As ground seed is fed continuously into the mechanical press, a worm screw increases the pressure progressively as the material moves through a slotted barrel. Pressures from 700 to 2,100 kilograms per square centimetre are attained, and the oil is squeezed out through the slots, leaving a cake containing 3 to 3.5 percent oil under optimum processing and 4 to 5 percent oil under average conditions.

Hydrocarbon solvents

Solvent extraction. *Processes.* Cakes obtained by pressing operations still retain 3 to 15 percent of residual oil. When the value of the oil is considerably greater as oil than as a part of the meal, it is desirable to obtain more complete extraction with solvents. Modern commercial methods of solvent extraction use volatile purified hydrocarbons, especially the various grades of petroleum benzin (commonly known as petroleum ether, commercial hexane, or heptane). In large-scale operations, solvent extraction is a more economical means of recovering oil than is mechanical pressing. In the United States and increasingly in Europe, there are many instances of simple petroleum benzin extraction of seeds, mainly soybeans. For seeds or nuts containing a higher oil content than soybeans it became customary to press the material in screw presses to remove a large proportion of the oil before extraction. Since this prepressing also ruptures the cellular structures of oil-bearing materials, most of the residual oil is easily removed with solvents.

A typical extraction system consists of (1) cleaning to remove tramp iron, dirt, foreign weed seeds, and stones, (2) removing hulls or cortex in cracking, aspirating, or screening operations, (3) cracking or rough grinding the kernels, meats, or prepressed cake, (4) steaming (tempering or cooking) of the meats, (5) flaking the small pieces between smooth flaking rolls, (6) extracting the oil with solvent, (7) separating the meal, or marc, from the oil-solvent solution, called miscella, and (8) removing the solvent from both the miscella and the marc. The marc may be toasted or pelletized, or both, for use in animal feeds. Most extracted meals contain less than 1 percent of residual oil. The amount varies depending on the amount of prepressing, the type of material being extracted, and the efficiency of the extracting system.

Extractors. Solvent extraction was first practiced in Europe, using batch extractors for the recovery of additional oil from the residues obtained from mechanical pressing. The greater efficiency of solvent extraction encouraged direct application to oilseeds, and the batch extractor gradually gave way to continuous units in which fresh flakes are added continuously and subjected to a counterflow of solvent. One of the earliest continuous extractors, and a type still considered to be one of the best, was the Bollman or Hansa-Mühle unit from Germany, in which solvent percolates through oilseed flakes contained in perforated baskets moving on an endless chain. After the extraction cycle is complete, the baskets of extracted flakes are dumped automatically and then refilled with fresh flakes to initiate another cycle. Many extractor designs have been proposed, but only a few have found wide acceptance. In the DeSmet extractor, popular in Europe and in a number of developing countries, a bed of flakes on an endless horizontal traveling belt is extracted by solvent percolation. The Blaw-Knox Rotocell has become the most popular extractor in the huge American soybean industry. The flakes are conveyed into wedge-shaped segments of a large cylindrical vessel. Solvent percolating through the cells falls into the bottom of the extractor housing, where it is picked up by a series of pumps and recirculated countercurrent to the flakes.

PROCESSING OF EXTRACTED OIL

The extent of processing applied to fats depends on their source, quality, and ultimate use. Many fats are used for edible purposes after only a single processing step—*i.e.,* clarification by settling or filtering. Most cold-pressed oils (for example, cold-pressed olive, peanut, and some coconut and sunflower oils) can be used in food products without further processing. Tremendous quantities of butter and lard are used without special treatment after churning or rendering. The growing demand for bland-tasting and stable salad oils and shortening, however, has led to extensive processing techniques.

Refining. The nonglyceride components contribute practically all the colour and flavour to fats. In addition, such materials as the free fatty acids, waxes, colour bodies, mucilaginous materials, phospholipids, carotenoids, and gossypol (a yellow pigment found only in cottonseed oil) contribute other undesirable properties in fats used for edible and, to some extent, industrial purposes.

Batch and continuous refining

Alkali refining. Many of these can be removed by treating fats at 40° to 85° C (104° to 185° F) with an aqueous solution of caustic soda (sodium hydroxide) or soda ash (sodium carbonate). The refining may be done in a tank (in which case it is called batch or tank refining) or in a continuous system. In batch refining, the aqueous emulsion of soaps formed from free fatty acids, along with other impurities (soapstock), settles to the bottom and is drawn off. In the continuous system the emulsion is separated with centrifuges. After the fat has been refined, it is usually washed with water to remove traces of alkali and soapstock. Oils that have been refined with soda ash or ammonia generally require a light re-refining with caustic soda to improve colour. After water washing, the oil may be dried by heating in a vacuum or by filtering through a dry filter-aid material. The refined oil may be used for industrial purposes or may be processed further to edible oils. Usually, the refined oils are neutral (*i.e.,* neither acidic nor alkaline), free of material that separates on heating (break material), lighter in colour, less viscous, and more susceptible to rancidity.

Water refining. Water refining, usually called degumming, consists of treating the natural oil with a small amount of water, followed by centrifugal separation. The process is applied to many oils that contain phospholipids in significant amounts. Since the separated phospholipids are rather waxy or gummy solids, the term degumming was quite naturally applied to the separation. The separated phospholipid emulsion layer from oils such as corn (maize) and soybean oils may be dried (commercially, these products are called lecithin) and used as emulsifiers in such products as margarine, chocolate products, and emulsion paints. The degumming of crude soybean oil, which has an average phospholipid content of 1.8 percent, provides the primary source of commercial lecithin. To obtain products of lighter colour, hydrogen peroxide may be added as a bleaching agent during the drying of lecithin. The degummed oil may be used directly in industrial applications, such as in paints or alkyd resins, or refined with alkalies for ultimate edible consumption.

Bleaching. If further colour removal is desired, the fat may be treated with various bleaching agents. Heated oils are treated with fuller's earth (a natural earthy material that will decolorize oils), activated carbon, or activated clays. Many impurities, including chlorophyll and carotenoid pigments, are adsorbed onto such agents and removed by filtration. Bleaching often reduces the resistance of oils to rancidity, because some natural antioxidants are removed together with impurities. When many oils are heated to more than 175° C (347° F), a phenomenon known as heat bleaching takes place. Apparently the heat decomposes some pigments, such as the carotenoids, and converts them to colourless materials.

Removing traces of wax

Destearinating or winterizing. It is often desirable to remove the traces of waxes (*e.g.,* cuticle wax from seed coats) and the higher-melting glycerides from fats. Waxes can generally be removed by rapid chilling and filtering. Separation of high-melting glycerides, or stearine, usually requires very slow cooling in order to form crystals that are large enough to be removed by filtration or centrifuging. Thus linseed oil may be winterized to remove traces of waxes that otherwise interfere with its use in paints and varnishes. Stearine may be removed from fish oils in order to separate the solid glycerides that would detract from its use in paints and alkyd resins. At the same time, fish stearine is more suitable than whole oil for edible purposes. Cottonseed and peanut oils may be destearinated to produce salad oils that remain liquid at low temperatures. Tallows and other animal fats may be destearinated for simultaneous production of hard fats (high in stearic acid content for special uses such as in making candles) and of liquid oil called oleo oil.

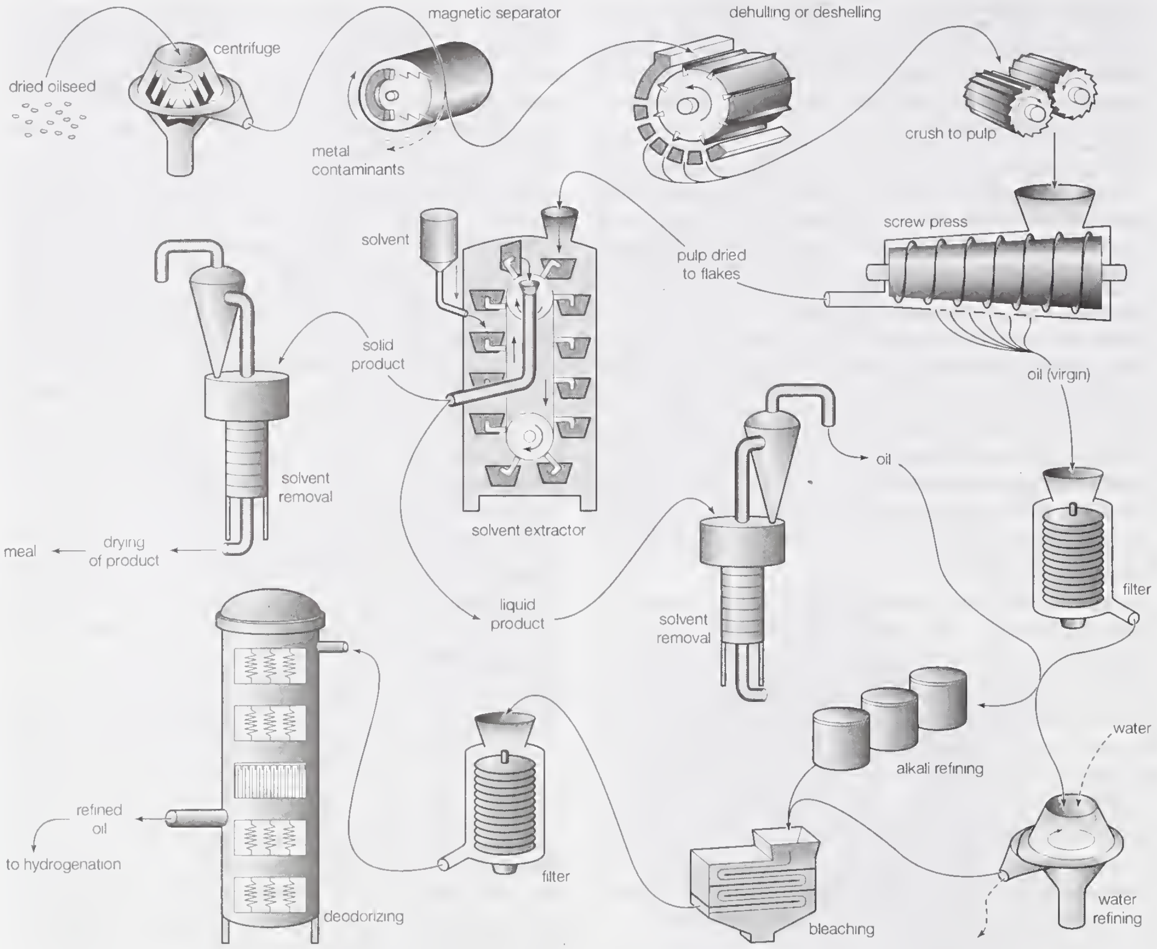

Figure 13: Essential steps in the extracting and refining of edible oil from oilseeds.
Encyclopædia Britannica, Inc.

Hydrogenation. For many edible purposes and for some commercial applications it is desirable to produce solid fats. Many shortenings and margarines contain hydrogenated (hardened) oils as their major ingredients. The development of margarine and shortening products resulted from the invention of a successful method for converting low-melting unsaturated fatty acids and glycerides to higher-melting saturated products. The process consists of the addition of hydrogen in the presence of a catalyst to the double (unsaturated) bonds. Thus oleic or linoleic acid (or their acid radicals in glycerides), which are normally liquid at room temperature, can be converted to stearic acid or the acid radical by the addition of hydrogen.

Limited use was made of this hydrogenation technology in Europe; the greatest potential use for the process lay in the United States, where a vast production of cottonseed oil, a by-product of the Southern cotton industry, awaited developments that would permit its conversion to a plastic fat. The hardening of cottonseed oil in the early 1900s gave birth to the shortening industry. Practical hydrogenation then spread to all countries where margarines and shortenings are produced from liquid oils.

Hydrogenation reactions. In commercial practice, hydrogenation is usually carried out with vigorous agitation or hydrogen dispersion with a narrow range of catalyst concentration (about 0.05 to 0.10 percent of finely divided nickel suspended on kieselguhr, or diatomaceous earth) in a steel pressure-reaction vessel. The ordinary ranges of temperature and pressure are from 100° to 200° C (212° to 392° F) and from atmospheric pressure to 42 kilograms per square centimetre, respectively. These conditions can be controlled to make the hydrogenation reaction somewhat selective—*i.e.,* to add hydrogen to the linolenic (three double bonds) and linoleic (two double bonds) acid radicals before adding to the oleic (one double bond) acid radicals. The most unsaturated fatty acid groups are most easily hydrogenated and thus react first with the hydrogen if conditions are right. Copper-containing catalysts are especially selective in the hydrogenation of vegetable oils. If very hard fats with low amounts of unsaturation are desired and selectivity is unimportant, higher temperatures and pressures are employed to shorten the reaction time and to use partially spent catalyst that would otherwise be wasted. After hydrogenation, the hot oil is filtered to remove the metallic catalyst for either reuse or recovery.

Isomerization reactions. During the catalytic treatment another reaction also takes place—isomerization (rearrangement of the molecular structure) of unsaturated fatty acid radicals to form isooleic, isolinoleic, and similar groups. Because these isomers have higher melting points than do the natural acids, they contribute to the hardening effect. The unsaturation of natural oils has the *cis* configuration, in which hydrogen atoms lie on one side of a plane cutting through the double bond and alkyl groups lie on the other side. During hydrogenation some of the unsaturation is converted to the *trans* configuration, with like groups on opposite sides of the plane. The *trans* isomers are much higher melting than the natural *cis* form. Simultaneously with the change of some of the unsaturation to the *trans* configuration there is a migration of double bonds along the chain. Thus isomers of oleic acid may be formed with the double bond in any position from carbon atom 2 to carbon atom 17. Many of these isomerized acids are higher melting than the natural oleic acid. Infrared analysis is useful for quantitative measurement of changes occurring during hydrogenation.

Rearrangement of molecular structure

Deodorization. Odourless and tasteless fats first came into high demand as ingredients for the manufacture of margarine, a product designed to duplicate the flavour and texture of butter. Most fats, even after refining, have characteristic flavours and odours, and vegetable fats especially have a relatively strong taste that is foreign to that of butter. The deodorization process consists of blowing steam through heated fat held under a high vacuum. Small quantities of volatile components, responsible for tastes and odours, distill, leaving a neutral, virtually odourless fat that is suitable for the manufacture of bland shortening or delicately flavoured margarine. Originally, deodorization was a batch process, but increasingly, continuous systems are being used in which hot fat flows through an evacuated column countercurrent to the upward passage of steam. In Europe, a deodorization temperature of 175°–205° C (347°–401° F) is common, but in the United States, higher temperatures of 235°–250° C (455°–483° F) are usually employed. About 0.01 percent of citric acid is commonly added to deodorized oils to inactivate trace-metal contaminants such as soluble iron or copper compounds that otherwise would promote oxidation and the development of rancidity.

Characteristics of cooking oils

Olive oil is invariably marketed in undeodorized form. The natural flavour is an important asset, and olive oil, as is true of butter, commands a premium in the market because of its distinctive and prized flavour. The common cooking oils of Asia—soybean, rapeseed, peanut, sesame, and coconut—are consumed in their crude form as expressed from oilseeds. In contrast, deodorized oils are in particular demand in the United States and Europe. For many years the only important vegetable oil consumed in the United States was cottonseed oil, which in its crude form has such a strong and unpleasant flavour that further processing was an absolute necessity in order to render it suitable for consumption. Because of widespread sale of neutral-flavoured cottonseed oil products over many years, a general preference was developed for odourless and tasteless fats.

Another reason for the practice of deodorizing edible oils in Europe and America relates to differences in oil quality by Western and Eastern extraction techniques. In China and Southeast Asia, edible oils have been produced principally by small, relatively crude equipment. The yield of oil is relatively low, and a minimum amount of nonglyceride substances is expressed from the seed, with the result that the flavour of the oil is fairly mild. In Europe and the United States, oil extraction is carried out in large factories that operate on an extremely competitive basis. Very-high-pressure expression or solvent extraction is used, and in order to improve yields the seeds are heat-treated prior to extraction. Oils obtained in high yield under such conditions are stronger in flavour than oils prepared by low-pressure expression, and the refining and deodorizing steps are required to improve palatability. The improvement in yields more than compensates for the added costs of refining and deodorizing.

When fats are hydrogenated for manufacture of margarine and shortening, they develop a characteristic sweet, but rather unpleasant, "hydrogenation odour" that must be removed from edible fats by deodorization.

(A.R.B./M.W.F./Ed.)

Bakery products

Baking, a dry-heat cooking process, is probably the oldest cooking method. Bakery products are usually prepared from flour or meal derived from some form of grain. Bread, already a common staple in prehistoric times, provides many nutrients in the human diet.

HISTORY

The earliest processing of cereal grains probably involved parching or dry roasting of collected grain seeds. Flavour, texture, and digestibility were later improved by cooking whole or broken grains with water, forming gruel or porridge. It was a short step to the baking of a layer of viscous gruel on a hot stone, producing primitive flat bread. More sophisticated versions of flat bread include the Mexican tortilla, made of processed corn, and the chapati of India, usually made of wheat.

Yeast leavening

Baking techniques improved with the development of an enclosed baking utensil and then of ovens, making possible thicker baked cakes or loaves. The phenomenon of fermentation, with the resultant lightening of the loaf structure and development of appealing flavours, was probably first observed when doughs or gruels, held for several hours before baking, exhibited spoilage caused by yeasts. Some of the effects of the microbiologically induced changes were regarded as desirable, and a gradual acquisition of control over the process led to traditional methods for making leavened bread loaves. Early baked products were made of mixed seeds with a predominance of barley, but wheat flour, because of its superior response to fermentation, eventually became the preferred cereal among the various cultural groups sufficiently advanced in culinary techniques to make leavened bread.

Brewing and baking were closely connected in early civilizations. Fermentation of a thick gruel resulted in a dough suitable for baking; a thinner mash produced a kind of beer. Both techniques required knowledge of the "mysteries" of fermentation and a supply of grain. Increasing knowledge and experience taught the artisans in the baking and brewing trades that barley was best suited to brewing, while wheat was best for baking.

By 2600 BC the Egyptians, credited with the first intentional use of leavening, were making bread by methods similar in principle to those of today. They maintained stocks of sour dough, a crude culture of desirable fermentation organisms, and used portions of this material to inoculate fresh doughs. With doughs made by mixing flour, water, salt, and leaven, the Egyptian baking industry eventually developed more than 50 varieties of bread, varying the shape and using such flavouring materials as poppyseed, sesame, and camphor. Samples found in tombs are flatter and coarser than modern bread.

The Egyptians developed the first ovens. The earliest known examples are cylindrical vessels made of baked Nile clay, tapered at the top to give a cone shape and divided inside by a horizontal shelflike partition. The lower section is the firebox, the upper section is the baking chamber. The pieces of dough were placed in the baking chamber through a hole provided in the top.

In the first two or three centuries after the founding of Rome, baking remained a domestic skill with few changes in equipment or processing methods. According to Pliny the Elder, there were no bakers in Rome until the middle of the 2nd century BC. As well-to-do families increased, women wishing to avoid frequent and tedious bread making began to patronize professional bakers, usually freed slaves. Loaves molded by hand into a spheroidal shape, generally weighing about a pound, were baked in a beehive-shaped oven fired by wood. *Panis artopticius* was a variety cooked on a spit, *panis testuatis* in an earthen vessel.

Although Roman professional bakers introduced technological improvements, many were of minor importance, and some were essentially reintroductions of earlier developments. The first mechanical dough mixer, attributed to Marcus Virgilius Euryasaces, a freed slave of Greek origin, consisted of a large stone basin in which wooden paddles, powered by a horse or donkey walking in circles, kneaded the dough mixture of flour, leaven, and water.

Bakers' guilds

Guilds formed by the miller-bakers of Rome became institutionalized. During the 2nd century AD, under the Flavians, they were organized into a "college" with work rules and regulations prescribed by government officials. The trade eventually became obligatory and hereditary, and the baker became a kind of civil servant with limited freedom of action.

During the early Middle Ages, baking technology advances of preceding centuries disappeared, and bakers reverted to mechanical devices used by the ancient Egyptians and to more backward practices. But in the later Middle Ages the institution of guilds was revived and expanded. Several years of apprenticeship were necessary before an applicant was admitted to the guild; often an intermediate status as journeyman intervened between apprenticeship and full membership (master). The rise of the bakers' guilds reflected significant advances in technique. A 13th-century French writer named 20 varieties of bread varying in shape, flavourings, preparation method, and quality of the meal used. Guild regulations strictly governed size and quality. But outside the cities bread was usually baked in the home. In medieval England rye was the main ingredient of bread consumed by the poor; it was frequently diluted with meal made from other cereals or leguminous seeds. Not until about 1865 did the cost of white bread in England drop below brown bread.

At that time improvements in baking technology began to accelerate rapidly, owing to the higher level of technology generally. Ingredients of greater purity and improved functional qualities were developed, along with equipment reducing the need for individual skill and eliminating hand manipulation of bread doughs. Automation of mixing, transferring, shaping, fermentation, and baking processes began to replace batch processing with continuous operations. The enrichment of bread and other bakery foods with vitamins and minerals was a major accomplishment of the mid-20th-century baking industry.

INGREDIENTS

Flour, water, and leavening agents are the ingredients primarily responsible for the characteristic appearance, texture, and flavour of most bakery products. Eggs, milk, salt, shortening, and sugar are effective in modifying these qualities, and various minor ingredients may also be used.

Flour. Wheat flour is unique among cereal flours in that, when mixed with water in the correct proportions, its protein component forms an elastic network capable of holding gas and developing a firm spongy structure when baked. The proteinaceous substances contributing these properties are known collectively as gluten. The suitability of a flour for a given purpose is determined by the type and amount of its gluten content. These characteristics are controlled by the genetic constitution and growing conditions of the wheat from which the flour was milled, as well as the milling treatment applied.

Gluten

Low-protein, soft-wheat flour is appropriate for cakes, pie crusts, cookies (sweet biscuits), and other products not requiring great expansion and elastic structure. High-protein, hard-wheat flour is adapted to bread, hard rolls, soda crackers, and Danish pastry, all requiring elastic dough and often expanded to low densities by the leavening action.

Leavening agents. Pie doughs and similar products are usually unleavened, but most bakery products are leavened, or aerated, by gas bubbles developed naturally or folded in. Leavening may result from yeast or bacterial fermentation, from chemical reactions, or from the distribution in the batter of atmospheric or injected gases.

Yeast. All commercial breads, except salt-rising types and some rye bread, are leavened with bakers' yeast, composed of living cells of the yeast strain *Saccharomyces cerevisiae.* A typical yeast addition level might be 2 percent of the dough weight. Bakeries receive yeast in the form of compressed cakes containing about 70 percent water or as dry granules containing about 8 percent water. Dry yeast, more resistant to storage deterioration than compressed yeast, requires rehydration before it is added to the other ingredients. "Cream" yeast, a commercial variety of bakers' yeast made into a fluid by the addition of extra water, is more convenient to dispense and mix than compressed yeast, but it also has a shorter storage life and requires additional equipment for handling.

Bakers' yeast performs its leavening function by fermenting such sugars as glucose, fructose, maltose, and sucrose. It cannot use lactose, the predominant sugar of milk, or certain other carbohydrates. The principal products of fermentation are carbon dioxide, the leavening agent, and ethanol, an important component of the aroma of freshly baked bread. Other yeast activity products also flavour the baked product and change the dough's physical properties.

Conversion of sugars to carbon dioxide and ethanol

The rate at which gas is evolved by yeast during the various stages of dough preparation is important to the success of bread manufacture. Gas production is partially governed by the rate at which fermentable carbohydrates become available to the yeast. The sugars naturally present in the flour and the initial stock of added sugar are rapidly exhausted. A relatively quiescent period follows, during which the yeast cells become adapted to the use of maltose, a sugar constantly being produced in the dough by the action of diastatic enzymes on starch. The rate of yeast activity is also governed by temperature and osmotic pressure, the latter primarily a function of the water content and salt concentration.

Baking soda. Layer cakes, cookies (sweet biscuits), biscuits, and many other bakery products are leavened by carbon dioxide from added sodium bicarbonate (baking soda). Added without offsetting amounts of an acidic substance, sodium bicarbonate tends to make dough alkaline, causing flavour deterioration and discoloration and slowing carbon dioxide release. Addition of an acid-reacting substance promotes vigorous gas evolution and maintains dough acidity within a favourable range.

Carbon dioxide produced from sodium bicarbonate is initially in dissolved or combined form. The rate of gas release affects the size of the bubbles produced in the dough, consequently influencing the grain, volume, and texture of the finished product. Much research has been devoted to the development of leavening acids capable of maintaining the rate of gas release within the desired range. Acids such as acetic, from vinegar, or lactic, from sour milk, usually act too quickly; satisfactory compounds include cream of tartar (potassium acid tartrate), sodium aluminum sulfate (alum), sodium acid pyrophosphate, and various forms of calcium phosphate.

Baking powder. Instead of adding soda and leavening acids separately, most commercial bakeries and domestic bakers use baking powder, a mixture of soda and acids in appropriate amounts and with such added diluents as starch, simplifying measuring and improving stability. The end products of baking-powder reaction are carbon dioxide and some blandly flavoured harmless salts. All baking powders meeting basic standards have virtually identical amounts of available carbon dioxide, differing only in reaction time. Most commercial baking powders are of the double-acting type, giving off a small amount of available carbon dioxide during the mixing and makeup stages, then remaining relatively inert until baking raises the batter temperature. This type of action eliminates excessive loss of leavening gas, which may occur in batter left in an unbaked condition for long periods.

Double-acting baking powder

Entrapped air and vapour. Angel food cakes, sponge cakes, and similar products are customarily prepared without either yeast or chemical leaveners. Instead, they are leavened by air entrapped in the product through vigorous beating. This method requires a readily foaming ingredient capable of retaining the air bubbles, such as egg whites. To produce a cake of fine and uniform internal structure, the pockets of air folded in during beating are rapidly subdivided into small bubbles with such mixing utensils as wire whips, or whisks.

The vaporization of volatile fluids (*e.g.,* ethanol) under the influence of oven heat can have a leavening effect. Water-vapour pressure, too low to be significant at normal temperatures, exerts substantial pressure on the interior walls of bubbles already formed by other means as the interior of the loaf or cake approaches the boiling point. The expansion of such puff pastry as used for napoleons (rich desserts of puff pastry layers and whipped cream or custard) and *vol-au-vents* (puff pastry shells filled with meat, fowl, fish, or other mixtures) is entirely due to water-vapour pressure.

Shortening. Fats and oils are essential ingredients in nearly all bakery products. Shortenings have a tenderizing effect in the finished product and often aid in the manipulation of doughs. In addition to modifying the mouth feel or texture, they often add flavour of their own and tend to round off harsh notes in some of the spice flavours.

The common fats used in bakery products are lard, beef fats, and hydrogenated vegetable oils. Butter is used in some premium and specialty products as a texturizer and to add flavour, but its high cost precludes extensive use. Cottonseed oil and soybean oil are the most common processed vegetable oils used. Corn, peanut, and coconut oils are used to a limited extent; fats occurring in other ingredients, such as egg yolks, chocolate, and nut butters, can have a shortening effect if the ingredients are present in sufficient quantity.

Breads and rolls often contain only 1 or 2 percent shortening; cakes will have 10 to 20 percent; Danish pastries prepared according to the authentic formula may have about 30 percent; pie crusts may contain even more. High usage levels require those shortenings that melt above room temperature; butter and liquid shortenings, with their lower melting point, tend to leak from the product.

Commercial shortenings may include antioxidants, to retard rancidity, and emulsifiers, to improve the shortening effect. Colours and flavours simulating butter may also be added. Margarines, emulsions of fat, water, milk solids, and salt, are popular bakery ingredients.

Fats of any kind have a destructive effect on meringues and other protein-based foams; small traces of oil left on the mixing utensils can deflate an angel food cake to unacceptably high density.

The use of water in dough

Liquids. Water is the liquid most commonly added to doughs. Milk is usually added to commercial preparations in dried form, and any moisture added in the form of eggs and butter is usually minimal. Water is not merely a diluent or inert constituent; it affects every aspect of the finished product, and careful adjustment of the amount of liquid is essential to make the dough or batter adaptable to the processing method. If dough is too wet it will stick to equipment and have poor response to shaping and transfer operations; if too dry, it will not shape or leaven properly.

Water hydrates gluten, permitting it to aggregate in the form of a spongy cellular network, the structural basis of most bakery products. It provides a medium in which yeast can metabolize sugars to form carbon dioxide and flavouring components and allows diffusion of nutrients and metabolites throughout the mass. Water is an indispensable component of the baking-powder reaction, and it allows starch to gelatinize during baking and prevents interior browning of bakery products.

Water impurities affect dough properties. Water preferred for baking is usually of medium hardness (50 to 100 parts per million) with a neutral pH (degree of acidity), or slightly acid (low pH). Water that is too soft can result in sticky doughs, while very hard water may retard dough expansion by toughening the gluten (calcium ions, particularly, promote cross-linking of gluten protein molecules). Water sufficiently alkaline to raise the dough pH may have a deleterious effect on fermentation and on flour enzymes. Although strongly flavoured contaminants may affect the acceptability of the finished product, chlorides and fluorides at concentrations usually found in water supplies have little influence on bread doughs.

Eggs. The differences between yolks and whites must be recognized in considering the effect of eggs on bakery products. Yolks contain about 50 percent solids, of which 60 percent or more is strongly emulsified fat, and are used in bakery foods for their effect on colour, flavour, and texture. Egg whites, containing only about 12 percent solids, primarily protein, and no fat, are important primarily for their texturizing function and give foams of low density and good stability when beaten. When present in substantial amounts, they tend to promote small, uniform cell size and relatively large volume. Meringues and angel food cakes are dependent on egg white foams for their basic structure. Although fats and oils greatly diminish its foaming power, the white still contributes to the structure of layer cakes and similar confections containing substantial amounts of both shortening and egg products.

Egg products are available to bakers in frozen or dried form. Few commercial bakers break fresh eggs for ingredients because of labour costs, unstable market conditions, and sanitary considerations. Many bakers use dried egg products because of their greater convenience and superior storage stability over frozen eggs. Processed and stored correctly, dried egg products are the functional equivalent of the fresh material, although flavour of the baked goods may be affected adversely at very high usage levels.

Sweeteners. Normal wheat flour contains about 1 percent sugars. Most are fermentable compounds, such as sucrose, maltose, glucose, and fructose. Additional maltose is formed during fermentation by the action of amyloytic enzymes (from malt and flour) on the starch. Glucose and sucrose are the sugars most frequently added to doughs and batters. The action of yeast rapidly converts the sucrose to fructose and glucose (*i.e.,* invert sugar). Invert sugar can also be added.

Effects of sugar on doughs

Sweetening power is an important property of added sugars, but sugars also provide fermentables for yeast activity. Crust colour development is related to the amount of reducing sugars present, and a dough in which the sugars have been thoroughly depleted by yeast will produce a pale crust.

Doughs with high concentrations of dissolved substances retard fermentation because of the effect on yeast of the high osmotic pressure (low water activity) of the aqueous phase. Sugars constitute the bulk of dissolved materials in most doughs. For this reason, sweet yeast-leavened goods develop gas and expand more slowly than bread doughs.

YEAST-LEAVENED PRODUCTS

Breads and rolls. Most of the bakery foods consumed throughout the world are breads and rolls made from yeast-leavened doughs. The yeast-fermentation process leads to the development of desirable flavour and texture, and such products are nutritionally superior to products of the equivalent chemically leavened doughs, since yeast cells themselves add a wide assortment of vitamins and good quality protein.

White bread. Satisfactory white bread can be made from flour, water, salt, and yeast. (A "sourdough" addition may be substituted for commercial yeast.) Yeast-raised breads based on this simple mixture include Italian-style bread and French or Vienna breads. Such breads have a hard crust, are relatively light in colour, with a coarse and tough crumb, and flavour that is excellent in the fresh bread but deteriorates in a few hours. In the United States, commercially produced breads of this type are often modified by the addition of dough improvers, yeast foods, mold inhibitors, vitamins, minerals, and small quantities of enriching materials such as milk solids or shortening. Formulas may vary greatly from one bakery to another and between different sections of the country. The standard low-density, soft-crust bread and rolls constituting the major proportion of breads and rolls sold in the United States contain greater quantities of enriching ingredients than the lean breads described above.

Whole wheat bread. Whole wheat bread, using a meal made substantially from the entire wheat kernel instead of flour, is a dense, rather tough, dark product. Breads sold as wheat or part-whole-wheat products contain a mixture of whole grain meal with sufficient white flour to produce satisfactory dough expansion.

Rye bread. Bread made from crushed or ground whole rye kernels, without any wheat flour, such as pumpernickel, is dark, tough, and coarse-textured. Rye flour with the bran removed, when mixed with wheat flour, allows production of a bread with better texture and colour. In darker bread it is customary to add caramel colour to the dough. Most rye bread is flavoured with caraway seeds.

Potato bread. Potato bread, another variety that can be leavened with a primary ferment, was formerly made with a sourdough utilizing the action of wild yeasts on a potato mash and producing the typical potato-bread flavour. It is now commonly prepared from a white bread formula to which potato flour is added.

Sweet breads. *Ingredients.* Sweet goods made from mixtures similar to bread doughs include "raised" doughnuts, Danish pastries, and coffee cakes. Richer in shortening, milk, and sugar than bread doughs, sweet doughs often contain whole eggs, egg yolks, egg whites, or corresponding dried products. The enriching ingredients alter the taste, produce flakier texture, and improve nutritional quality. Spices such as nutmeg, mace, cinnamon, coriander, and ginger are frequently used for sweet-dough products; other common adjuncts include vanilla, nuts and nut pastes, peels or oils of lemon or orange, raisins, candied fruit pieces, jams, and jellies.

Danish dough. Although various portion-size sweet goods are often called "Danish pastry," the name originally referred only to products made by a special roll-in procedure, in which yeast-leavened dough sheets are interleaved with layers of butter and the layers are reduced in thickness, then folded and resheeted to obtain many thin layers of alternating shortening and dough. Danish doughs ordinarily receive little fermentation. Before the

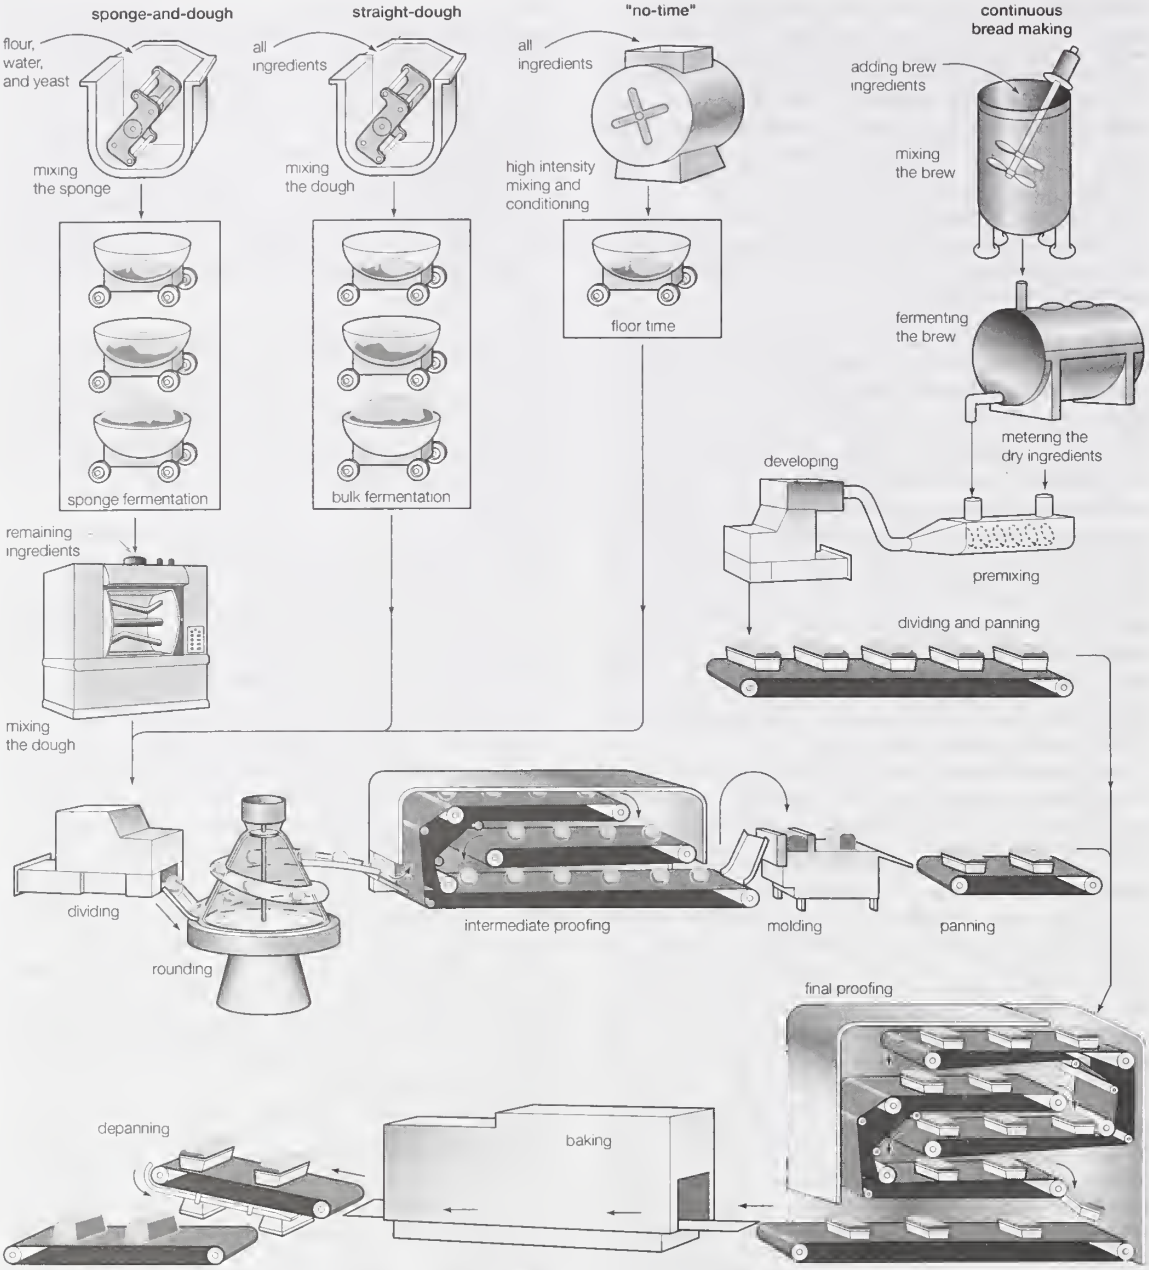

Figure 14: Essential steps in four commercial bread-making processes.
Encyclopædia Britannica, Inc.

fat is rolled in, there is a period of 20 to 30 minutes in the refrigerator, allowing gas and flavour to develop. Proof time, fermentation of the piece in its final shape, is usually only 20 to 30 minutes, at lower temperatures. When properly made, these doughs yield flaky baked products, rich in shortening, with glossy crusts.

Dough preparation. The process most commonly employed in preparing dough for white bread and many specialty breads is known as the sponge-and-dough method, in which the ingredients are mixed in two distinct stages. Another conventional dough-preparation procedure, used commonly in preparing sweet doughs but rarely regular bread doughs, is the straight-dough method, in which all the ingredients are mixed in one step before fermentation. In a less conventional method, known as the "no-time" method, the fermentation step is eliminated entirely. These processes are described below and illustrated in Figure 14.

The sponge-and-dough method. The sponge-and-dough mixing method consists of two distinct stages. In the first stage, the mixture, called the sponge, usually contains one-half to three-fourths of the flour, all of the yeast, yeast foods, and malt, and enough water to make a stiff dough. Shortening may be added at this stage, although it is usually added later, and one-half to three-fourths of the salt may be added to control fermentation. The sponge is customarily mixed in a large, horizontal dough mixer (see Figure 16), processing about one ton per batch, and usually constructed with heat-exchange jackets, allowing temperature control. The objectives of mixing are a nearly homogeneous blend of the ingredients and "developing" of the dough by formation of the gluten into elongated and interlaced fibres that will form the basic structure of the loaf. Because intense shearing actions must be avoided, the usual dough mixer has several horizontal bars, oriented parallel to the body of the mixer, rotating slowly at 35 to 75 revolutions per minute, stretching and kneading the dough by their action. A typical mixing cycle would be about 12 minutes.

Dough mixers

The mixed sponge is dumped into a trough (Figure 15), a shallow rectangular metal tank on wheels, and placed in an area of controlled temperature and humidity (*e.g.*, 27° C [80° F] and 75 percent relative humidity), where it is fermented until it begins to decline in volume. The time required for this process, called the drop or break, depends on such variables as temperature, type of flour, amount of yeast, absorption, and amount of malt, which

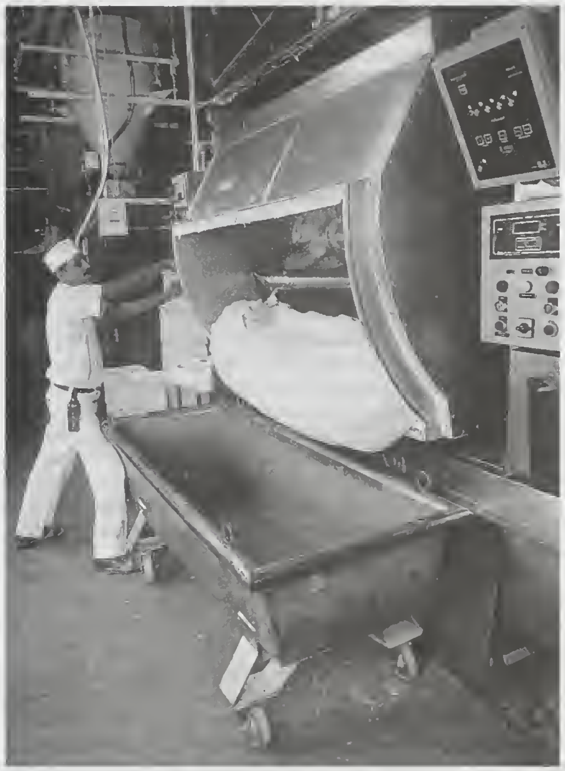

Figure 15: Transferral of bread "sponge" from dough mixer to trough prior to fermentation.
© Mathew Neal McVay/Tony Stone Images

are frequently adjusted to produce a drop in about three to five hours.

At the second, or dough, stage, the sponge is returned to the mixer, and the remaining ingredients are added. The dough is developed to an optimum consistency, then either returned to the fermentation room or allowed "floor time" for further maturation.

Advantages of the sponge-and-dough method include: (1) a saving in the amount of yeast (about 20 percent less is required than for a straight dough), (2) greater volume and more desirable texture and grain, and (3) greater flexibility allowed in operations because, in contrast to straight doughs (which must be taken up when ready), sponges can be held for later processing without marked deterioration of the final product.

The sponge method, however, involves extra handling of the dough, additional weighing and measuring, and a second mixing and thus has the disadvantage of increasing labour, equipment, and power costs.

The straight-dough method. Two of the many possible variations in the straight-dough process include the remixed straight-dough process, with a small portion of the water added at the second mix, and the no-punch method, involving extremely vigorous mixing. The straight-dough method is rarely used for white breads because it is not sufficiently adaptable to allow compensation for fluctuations in ingredient properties.

"No-time" methods. One set of procedures intended to eliminate the traditional bulk fermentation step are the "no-time" methods. Popular in the United Kingdom and Australia, these processes generally require an extremely energy-intensive mixing step, sometimes performed in a partially vacuumized chamber. Rather high additions of chemical oxidants, reducing agents, and other dough modifiers are almost always required in order to produce the desired physical properties. "No-time" is actually a misnomer, since there are always small amounts of floor time (periods when the dough is awaiting further processing) during which maturing actions lead to improvements in the dough's physical properties. Even then, the flavour of the bread cannot be expected to match that of a traditionally processed loaf.

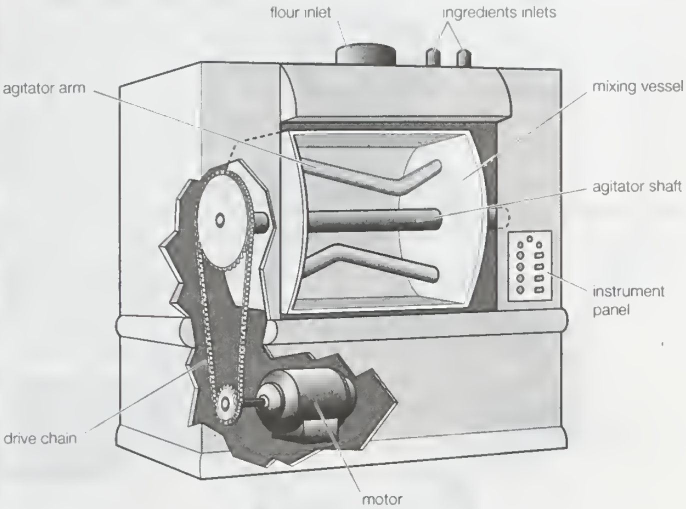

Figure 16: The drive and mixing elements of a horizontal mixer.
Encyclopædia Britannica, Inc.

Makeup. After the mass of dough has completed fermentation (and has been remixed if the sponge-and-dough process is employed), it is processed by a series of devices loosely classified as makeup equipment. In the manufacture of pan bread, makeup equipment includes the divider, the rounder, the intermediate proofer, the molder, and the panner.

Dividing. The filled trough containing remixed dough is moved to the divider area or to the floor above the divider. The dough is dropped into the divider hopper, which cuts it into loaf-size pieces (see Figure 17). Two methods are employed. In the volumetric method, the dough is forced into pockets of a known volume. The pocket contents are cut off from the main dough mass and then ejected onto a conveyor leading to the rounder. When density is kept constant, weight and volume of the dough pieces are roughly the same. In the weight-based method, a cylindrical rope of dough is continuously extruded through an orifice at a fixed rate and is cut off by a knife-edged rotor at fixed intervals. Since the dough is of consistent density, the cut pieces are of uniform weight. Like the pocket-cut pieces, the cylindrical pieces are conveyed to the rounder.

Rounding. Dough pieces leaving the divider are irregular in shape, with sticky cut surfaces from which the gas can readily diffuse. Their gluten structure is somewhat disoriented and unsuitable for molding. The rounder closes these cut surfaces, giving each dough piece a smooth and

Function of the rounder

dry exterior; forms a relatively thick and continuous skin around the dough piece, reorienting the gluten structure; and shapes the dough into a ball for easier handling in subsequent steps. It performs these functions by rolling the well-floured dough piece around the surface of a drum or cone, moving it upward or downward along this surface by means of a spiral track (see Figure 18). As a result of this action, the surface is dried both by the even distribution of dusting flour and by dehydration resulting from exposure to air; the gas cells near the surface of the ball are collapsed, forming a thick layer inhibiting the diffusion of gases from the dough; and the dough piece assumes an approximately spherical shape.

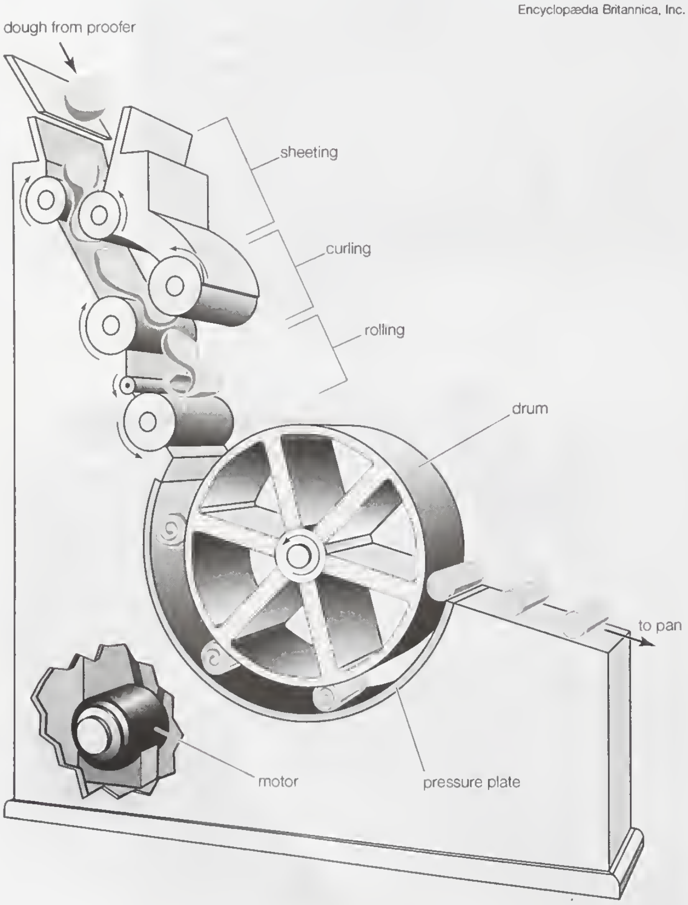

Figure 19: The formation of dough cylinders in a drum molder.
Encyclopædia Britannica, Inc.

Intermediate proofing. Dough leaving the rounder is almost completely degassed. It lacks extensibility, tears easily, has rubbery consistency, and has poor molding properties. To restore a flexible, pliable structure, the dough piece must be allowed to rest while fermentation proceeds. This is accomplished by letting the dough ball travel through an enclosed cabinet, the intermediate proofer, for several minutes. Physical changes, other than gas accumulation, occurring during this period are not yet understood, but there are apparently alterations in the molecular structure of the dough rendering it more responsive to subsequent operations. Upon leaving the intermediate proofer, the dough is more pliable and elastic, its volume is increased by gas accumulation, and its skin is firmer and drier.

Restoring dough structure

Most intermediate proofers are the overhead type, in which the principal part of the cabinet is raised above the floor, allowing space for other makeup machinery beneath it. Interior humidity and temperature depend on humidity accumulating from the loaves and on ambient temperatures.

Molding. The molder receives pieces of dough from the intermediate proofer and shapes them into cylinders ready to be placed in the pans. There are several types of molders, but all have four functions in common: sheeting, curling, rolling, and sealing (see Figure 19). The dough as it comes from the intermediate proofer is a flattened spheroid; the first function of the molder is to flatten it into a thick sheet, usually by means of two or more consecutive pairs of rollers, each succeeding pair set more closely together than the preceding pair. The sheeted dough is curled into a loose cylinder by a special set of rolls or by a pair of canvas belts. The spiral of dough in the cylinder is not adherent upon leaving the curling section, and the next operation of the molder is to seal the dough piece, allowing it to expand without separating into layers. The conventional molder rolls the dough cylinder between a large drum and a smooth-surfaced semicircular compression board. Clearance between the drum and board is gradually reduced, and the dough, constantly in contact with both surfaces, becomes transversely compressed.

Panning. An automatic panning device is an integral part of most modern molders. As empty pans, carried on a conveyor, pass the end of the machine, the loaves are transferred from the molder and positioned in the pans by a compressed air-operated device. Before the filled pans are taken to the oven, the dough undergoes another fermentation, or pan-proofing, for about 20 minutes at temperatures of 40° to 50° C, or 100° to 120° F.

Continuous bread making. Many steps in conventional dough preparation and makeup have been fully automated, but none of the processes is truly continuous. In continuous systems, the dough is handled without interruption from the time the ingredients are mixed until it is deposited in the pan. The initial fermentation process is still essentially a batch procedure, but in the continuous bread-making line the traditional sponge is replaced by a liquid pre-ferment, called the broth or brew. The brew consists of a mixture of water, yeast, sugar, and portions of the flour and other ingredients, fermented for a few hours before being mixed into the dough.

Fermenting a liquid brew

As shown in Figure 14, after the brew has finished fermenting, it is fed along with the dry ingredients into a mixing device, which mixes all ingredients into a homogeneous mass. The batterlike material passes through a dough pump regulating the flow and delivering the mixture to a developing apparatus, where kneading work is applied. The developer is the key equipment in the continuous line. Processing about 50 kilograms (100 pounds) each 90 seconds, it changes the batter from a fluid mass having no organized structure, little extensibility, and inadequate gas retention to a smooth, elastic, film-forming dough. The dough then moves out of the developer into a metering device that constantly extrudes the dough and intermittently severs a loaf-size piece, which falls into a pan passing beneath.

Although ingredients are generally the same as those used in batch processes, closer control and more rigid specifications are necessary in continuous processing in order to assure the satisfactory operation of each unit. Changes in conditions cannot readily be made to compensate for changes occurring in ingredient properties. Oxidizers, such as bromate and iodate, are added routinely to compensate for the smaller amount of oxygen brought into the dough during mixing.

The use of fermented brews has been widely accepted in plants practicing traditional dough preparation and makeup. The handling of a fermentation mixture through pumps, pipes, valves, and tanks greatly increases efficiency and control in both batch-type and continuous systems.

Baking and depanning. *Ovens.* The output of all bread-making systems, batch or continuous, is usually keyed to the oven, probably the most critical equipment in the bakery. Most modern commercial bakeries use either the tunnel oven, consisting of a metal belt passing through a connected series of baking chambers open only at the ends, or the tray oven, with a rigid baking platform carried on chain belts. Other types include the peel oven, having a fixed hearth of stone or brick on which the loaves are placed with a wooden paddle or peel; the reel oven, with shelves rotating on a central axle in Ferris wheel fashion; the rotating hearth oven; and the draw plate oven.

Advances in high-capacity baking equipment include a chamber oven with a conveyor that carries pan assemblies (called straps) along a roughly spiral path through an insulated baking chamber. The straps are automatically added to the conveyor before it enters the oven and then automatically removed and the bread dumped at the conveyor's exit point. Although the conveyor is of a complex design, the oven as a whole is considerably simpler than most other high-capacity baking equipment and can be operated with very little labour. As a further increase in efficiency, the conveyor can also be designed to carry filled pans in a continuous path through a pan-proofing enclosure and then through the oven.

The rack oven for small bakeries

In small to medium-size retail bakeries, baking may be done in a rack oven. This consists of a chamber, perhaps two to three metres high, that is heated by electric elements or gas burners. The rack consists of a steel framework having casters at the bottom and supporting a vertical array of shelves. Bread pans containing unbaked dough pieces are placed on the shelves before the rack is pushed mechanically or manually into the oven. While baking is taking place, the rack may remain stationary or be slowly rotated.

Most ovens are heated by gas burned within the chamber, although oil or electricity may be used. Burners are sometimes isolated from the main chamber, heat transfer then occurring through induced currents of air. Baking reactions in the oven are both physical and chemical in nature. Physical reactions include film formation, gas expansion, reduction of gas solubility, and alcohol evaporation. Chemical reactions include yeast fermentation, carbon dioxide formation, starch gelatinization, gluten coagulation, sugar caramelization, and browning.

Depanners. Automatic depanners, removing the loaves from the pans, either invert the pans, jarring them to dislodge the bread, or pick the loaves out of the pans by means of suction cups attached to belts.

CHEMICALLY LEAVENED PRODUCTS

Many bakery products depend on the evolution of gas from added chemical reactants as their leavening source. Items produced by this system include layer cakes, cookies, muffins, biscuits, corn bread, and some doughnuts.

The gluten proteins of the flour serve as the basic structural element in chemically leavened foods, just as they do in bread. The relatively smaller amounts of flour, the weaker (less extensible) protein in the soft-wheat flours customarily employed, and the lower protein content of the flour, however, result in a softer, crumblier texture. In most chemically leavened foods, the protein content of the flour, inadequate in quantity and quality to support the amount of expansion required in bread, produces a product of higher density.

Prepared mixes and doughs. Prepared dry mixes, available for home use and for small and medium-size commercial bakeries, vary in complexity from self-rising flour, consisting only of salt, leavening ingredients, and flour, to elaborate cake mixes. Mixes offer the consumer ingredients measured with greater accuracy than possible with kitchen utensils and special ingredients designed for functional compatibility.

Prepared doughs for such products as biscuits and other quick breads, packaged in cans of fibre and foil laminates, are available in refrigerated form. These products carry the mix concept two steps further; the dough or batter is premixed and shaped. Unlike ordinary canned products, refrigerated doughs are not sterile but contain microbes from normal ingredient contamination. Spoilage is retarded by low storage temperature, low oxygen tension, and the high osmotic pressure of the aqueous phase.

Frozen batters

Many boutique cookie bakeries and muffin shops that operate in shopping malls and similar locations generally use frozen batters shipped from a central plant. These batters are thawed a day or so before use, and a measured amount is scooped from the container and placed on a baking pan immediately before insertion into the oven. In this way, freshly baked cookies or muffins can be prepared in many varieties with a small amount of unskilled labour and a minimum of specialized equipment. In some cases, a central commissary supplies fully baked but frozen products, which are simply thawed (and sometimes iced and decorated) before sale.

Dough and batter formulas. *Hot breads.* Hot breads, such as biscuits, muffins, pancakes, and scones, constitute a large and important class of chemically leavened bakery foods. They consist of flour, baking powder, salt, and liquid, with varying amounts of eggs, milk, sugar, and shortening. Other variations include the addition of fruits such as raisins, condiments such as peppers, and adjuncts such as cheese. In corn breads a considerable proportion of the flour is replaced by cornmeal. Mixing and forming methods, and the baking conditions applied, also affect product appearance, texture, and flavour. For example, a batter suitable for making corn bread might also be used to make muffins or pancakes, and each kind of finished product would vary not only in appearance but also in flavour and texture. Recipes for hot breads usually contain not more than about 15 percent shortening and 5 percent sugar. Eggs, when used, are customarily whole eggs. Milk is often used both for flavour and for its texturizing and crust coloration properties.

Cakes. There are traditional rules for assuring "formula balance," or the correct proportioning of ingredients, in layer cakes. For every 10 parts of flour, yellow layer cakes should contain 10 to 16 parts sugar by weight, and white layer cakes should contain 11 to 16 parts sugar. Shortening should range from 3 to 7 parts for each 10 parts of flour. The weight of liquid whole eggs should equal or exceed that of the shortening in the mixture. Total water, including the moisture in eggs and milk, should exceed the amount of sugar by $2^{1}/_{2}$ to $3^{1}/_{2}$ parts. Baking-powder weight should equal from 3 to 6 percent of flour weight; salt should equal 3 to 4 percent of flour weight. If the amount of sugar in a formula is increased, the egg content should be increased an equal amount, and more shortening should be added when the percentage of eggs is increased. Additional water is rarely added when the formula contains dry milk, but if the formula water is not sufficient to equal the reconstitution water for the milk, about 1 percent of water for each additional percent of milk solids is added.

Common cake varieties include white cake, similar in formula to yellow cake, except that the white cake uses egg whites instead of whole eggs; devil's food cake, differing from chocolate cake chiefly in that the devil's food batter is adjusted to an alkaline level with sodium bicarbonate; chiffon cakes, deriving their unique texture from the effect of liquid shortening on the foam structure; and gingerbread, similar to yellow cake but containing large amounts of molasses and spices.

Cookies. Recipes for cookies (called biscuits or sweet biscuits in some countries) are probably more variable than those for any other type of bakery product. Some layer-cake batters can be used for soft drop cookies, but most cookie formulas contain considerably less water than cake recipes, and cookies are baked to a lower moisture content than any normal cake. With the exception of soft types, the moisture content of cookies will be below 5 percent after baking, resulting in crisp texture and good storage stability.

Low moisture content

Cookies are generally high in shortening and sugar. Milk and eggs are not common ingredients in commercial cookies but may be used in home recipes. Sugar granule size has a pronounced effect on cookie texture, influencing spread and expansion during baking, an effect partly caused by competition for the limited water content between the slowly dissolving sugar and the gluten of the flour.

Equipment. *Mixing.* The horizontal dough mixers used for yeast-leavened products may be used for mixing chemically leavened doughs and batters. Mixers may be the batch type, similar in configuration to the household mixer, with large steel bowls, open at the top, containing the batter while it is mixed or whipped by beater paddles of various conformations. In continuous mixers the batter is pumped through an enclosed chamber while a toothed disk rapidly rotates and mixes the ingredients. The chambers may be pressurized to force gas into the batter and surrounded with a flowing heat-transfer medium to adjust the temperature.

Sheeting and cutting. Chemically leavened doughs can be formed by methods similar to those used for yeast-leavened doughs of similar consistency. In the usual sequence, the dough passes between sets of rollers, forming sheets of uniform thickness; the desired outline is cut in the sheet by stamping pressure or embossed rollers; and the scrap dough is removed for reprocessing. Many cookies and crackers are made in this way, and designs may be impressed in the dough pieces by docking pins (used primarily to puncture the sheet, preventing formation of excessively large gas bubbles) or by cutting edges partially penetrating the dough pieces.

Die forming and extruding. In addition to the sheeting and cutting methods, cookies may be shaped by die forming and extrusion. In die forming a dough casing may be applied around a centre portion of jam or other material, forming products such as fig bars; or portions of dough may be deposited, forming such drop-type cookies as vanilla wafers, chocolate chip, and oatmeal cookies. Extrusion is accomplished by means of a die plate having orifices that may be circular, rectangular, or complex in outline. The mass of dough, contained in a hopper, is pushed through these openings, forming long strands of dough. Individual cookies are formed by separating pieces from the dough strand with a wire passing across the outer surface of the die or by pulling apart the hopper and oven belt (to which the dough adheres).

Extrusion of cookies

Rotary molding. Cookies produced on rotary molders include sandwich-base cakes and pieces made with embossed designs. A steel cylinder, the surface covered with shallow engraved cavities, rotates past the opening in a hopper filled with cookie dough. The pockets are filled with the dough, which is sheared off from the main mass by a blade, and, as the cylinder continues its revolution, the dough pieces are ejected onto a conveyor belt leading to the band oven.

Baking. Most commercial ovens for chemically leavened products are the band types, although reel ovens are still used, especially in smaller shops or bakeries where short runs are frequent.

AIR- AND STEAM-LEAVENED PRODUCTS

Air leavening. Air-leavened bakery products, avoiding the flavours arising from chemical- and yeast-leavening systems, are particularly suitable for delicately flavoured cakes. Since the batters can be kept on the acidic side of neutrality, the negative influence of chemical leaveners on fruit flavours and vanilla is avoided.

Foaming action of protein

Foams and sponges. The albumen of egg white, a protein solution, foams readily when whipped. The highly extended structure has little strength and must be supported during baking by some other protein substance, usually the gluten of flour. Because the small amount of lipids in flour tend to collapse the albumen foam, flour is gently folded into egg white foams, minimizing contact of fatty substances with the protein. Gluten sponges are denser than the lightest egg-white foams but are less subject to fat collapse.

The foam of egg yolks and whole eggs, as in pound cakes, is an air-in-oil emulsion. Proteins and starch, scattered throughout the emulsion in a dispersed condition, gradually coalesce as the batter stands or is heated. Fats and oils, in addition to yolk lipids, can be added to such systems without causing complete collapse but never achieve the low density possible with protein foams and usually have a tender, crumbly texture, unlike the more elastic structure of albumen-based products.

Wafers and biscuits. Rye wafers made of whipped batters are modern versions of an ancient Scandinavian food. High-moisture dough or batter, containing a substantial amount of rye flour and some wheat flour, is whipped, extruded onto an oven belt, scored and docked, then baked slowly until almost dry. Alternatively, the strips of dough may be cut after they are baked.

Beaten biscuits, an old specialty of the American South, are also made from whipped batter. Air is beaten into a stiff folded dough with many strokes of a rolling pin or similar utensil. Round pieces cut from the dough are pricked with a fork to prevent development of large bubbles, then baked slowly. The baked biscuit is similar to a soft cracker.

Steam leavening. All leavened products rely to some extent on water-vapour pressure to expand the vesicles or gas bubbles during the latter stages of baking, but some items also utilize the leavening action produced by the rapid buildup of steam as the interior of the product reaches the boiling point. These foods include puff pastries, used for patty shells and napoleons, and chou pastes, often used for cream-puff and éclair cases.

Puff pastry. Puff pastry, often used in French pastries, is formed from layered fat and dough. The proportion of fat is usually high, rarely less than 30 percent of the finished raw piece. The dough should be extensible but not particularly elastic; for this reason mixtures of hard and soft wheat flour are often used. The fat should have an almost waxy texture and must remain solid through the sheeting steps. Butter, although frequently used, is not particularly suitable for puff pastry because its low melting point causes it to blend into the dough during the sheeting process. Bakers specializing in puff pastry often use special margarines containing high-melting-point fats.

Puff pastry production methods

There are several methods of making puff pastry. In the basic procedure dough is rolled into a rectangular layer of uniform thickness, and the fat is spread over two-thirds of the surface. The dough is next folded, producing three dough strata enclosing two fat layers. This preparation is next chilled by refrigeration, then rolled, reducing thickness until it reaches approximately the area of the original unfolded dough. The folding, refrigeration, and rolling procedure is repeated several times, and after the final rolling the dough is reduced to the thickness desired in the shaped raw piece.

Correctly prepared puff pastry will expand as much as 10 times during baking because of the evolution of large volumes of steam at the interface between shortening and dough. The focuses for gassing are the microscopic air bubbles rolled into the dough during the layering process. If layering has been properly conducted, the finished pieces will be symmetrical and well-shaped, with crisp, flaky outer layers.

Chou paste. Chou paste, used for cream puffs, is made by an entirely different method. Flour, salt, butter, and boiling water are mixed together, forming a fairly stiff dough, and whole eggs are incorporated by beating. Small pieces of the dough are baked on sheets, initially at high temperature. The air bubbles formed during mixing expand rapidly at baking temperatures, filling the interior with large, irregular cells, while the outside browns and congeals, forming a rather firm case. The interior, largely hollow, can be injected with such sweet or savoury fillings as whipped cream or shrimp in sauce.

MARKET PREPARATION

Slicing. Bread often is marketed in sliced form. Slicing is performed by parallel arrays of saw blades through which the loaves are carried by gravity or by conveyors. The blades may be endless bands carried on rotating drums, or relatively short strips held in a reciprocating frame. Most bread is sliced while still fairly warm, and the difficulty of cutting the sticky, soft crumb has led to development of coated blades and blade-cleaning devices. Horizontal slicing of hamburger rolls and similar products is accomplished by circular (disk) blades, usually two blades in a slicer, between which a connected array of four or six rolls is carried by a belt. The cutter blades are separated to avoid cutting completely through the roll, in order to leave a "hinge."

Quality control in freezing

Freezing. Freezing is an indispensable bakery industry process. Ordinary bread and rolls are rarely distributed and sold in frozen form because of the excessive cost in relation to product value, but a substantial percentage of all specialty products is sold in frozen form. Most bakery products respond well to freezing, although some cream fillings must be specially formulated to avoid syneresis, or gel breakdown. Rapid chilling in blast freezers is preferred, although milder methods may be used. Storage at −18° C (0° F) or lower is essential for quality maintenance. Thawing and refreezing is harmful to quality. Frozen bakery products can dehydrate under freezer conditions and must be packaged in containers resistant to moisture-vapour transfer.

Wrapping. Most American consumers prefer wrapped bread, and the trend toward wrapping is growing in other countries. Sanitary and aesthetic considerations dictate protection of the product from environmental contamination during distribution and display. Waxed paper was originally the only film used to package bread; then cellophane became popular; and finally polyethylene, polypropylene, and combination laminates became common. Other bakery products are packaged in a variety of containers ranging from open bags of greaseproof material to plastic trays with sealed foil overwraps.

QUALITY MAINTENANCE

Spoilage by microbes. Bakery products are subject to the microbiological spoilage problems affecting other foods. If moisture content is kept below 12 to 14 percent (depending on the composition), growth of yeast, bacteria, and molds is completely inhibited. Nearly all crackers and cookies fall below this level, although jams, marshmallow, and other adjuncts may be far higher in moisture content. Breads, cakes, sweet rolls, and some other bakery foods may contain as much as 38 to 40 percent water when freshly baked and are subject to attack by many fungi and a few bacteria.

Fungi. To obtain maximum shelf life free of mold spoilage, high levels of sanitation must be maintained in baking and packing areas. Oven heat destroys all fungal life-forms, and any spoilage by these organisms is due to reinoculation after baking. A number of compounds have been proposed for use as fungistats in bread. Some have proved to be innocuous to molds, toxic to humans, or both. Soluble salts of propionic acid, principally sodium propionate, have been accepted and extend shelf life appreciably in the absence of a massive inoculum. Sorbic acid (or potassium sorbate) and acetic acid also have a protective effect.

The only widespread food poisoning in which bread has been a vector has resulted from ergot, a fungus infection of the rye plant. Ergot contamination of bread made from rye, or from blends of rye and wheat, has caused epidemics leading to numerous deaths.

Bacteria. Bacteria associated with bread spoilage include *Bacillus mesentericus*, responsible for "ropy" bread, and the less common but more spectacular *Micrococcus prodigiosus*, causative agent of "bleeding bread." Neither ropy bread nor bleeding bread is particularly toxic. Enzymes secreted by *B. mesentericus* change the starch inside the loaf into a gummy substance stretching into strands when a piece of the bread is pulled apart. In addition to ropiness, the spoiled bread will have an off-aroma sometimes characterized as fruity or pineapple-like. Formerly, when ropiness occurred, bakers acidified doughs with vinegar as a protective measure, but this type of spoilage is rare in bread from modern bakeries.

M. prodigiosus causes red spots to appear in bread. At an advanced stage these spots of high bacterial population may liquefy, emphasizing the similarity to blood, which has sometimes led the superstitious to attribute religious significance to this phenomenon. The organism will not survive ordinary baking temperatures, unlike *B. mesentericus*, which forms spores capable of survival in the centre of the loaf, where the temperature rises only to about 100° C (212° F).

Baked goods containing such high-moisture adjuncts as pastry creams and pie fillings are susceptible to contamination by food-spoilage organisms, including *Salmonella* and *Streptococcus*. Cream and custard pies are recognized health hazards when stored at room temperature for any length of time, and some communities ban their sale during summer. Storage in frozen form eliminates the hazard.

Structural changes in staling

Staling. Undesirable changes in bakery products can occur independently of microbial action. Staling involves changes in texture, flavour, and appearance. Firming of the interior, or "crumb," is a highly noticeable alteration in bread and other low-density, lean products. Elasticity is lost, and the structure becomes crumbly. Although loss of moisture produces much the same effect, texture staling can occur without any appreciable drying. Such firming is due to changes in the molecular status of the starch, specifically to a kind of aggregation of sections of the long-chain molecules into micelles, making the molecules more rigid and less soluble than in the newly gelatinized granule. Bread that has undergone texture staling can be softened by heating to about 60°–65° C (140°–150° F). However, its texture does not return to that of fresh bread, being gummier and more elastic. In addition, care must be exercised to prevent drying during heating.

Starch retrogradation, the cause of ordinary texture staling of the crumb, can be slowed by the addition of certain compounds to the dough. Most of the effective chemicals are starch-complexing agents. Monoglycerides of fatty acids have been widely used as dough additives to retard staling in the finished loaf. (S.A.M.)

Fruits

Fruit is sometimes defined as the product of growth from an angiosperm, or flowering plant. From a purely botanical point of view, the fruit may be only the fleshy growth that arises from the ovary of a flower and may not necessarily include any other structures. From the consumer's or food processor's point of view, however, fruit is generally characterized as the edible product of a plant or tree that includes the seed and its envelope and can typically be described as juicy, sweet, and pulpy. Typical fruit structures are illustrated in Figure 20.

Fruits are a high-moisture, generally acidic food that is relatively easy to process and that offers a variety of flavour, aroma, colour, and texture to the diet. They are usually low in calories but are an excellent source of dietary fibre and essential vitamins. Owing to the presence of cellulose, pectin, and various organic acids, fruits can also act as natural laxatives. Fruits are therefore a valuable part of the diet.

FRUIT CHARACTERISTICS

Nutrient composition. *Moisture content, acidity, and vitamin content.* As shown in Table 4, fresh fruit is typically between 75 and 95 percent water, a fact that helps to explain the refreshing character of the food. In general, fruits are acidic, with pH ranging from 2.5 to 4.5. The most common acids in fruits are citric acid, malic acid, and tartaric acid.

Vitamin C

Of all the vitamins present in fruits, the most noted is vitamin C, or ascorbic acid. Actual quantities of vitamin C in fruits are not especially large, but the vitamin is particularly important in the diet because of its role in the prevention of disease and in the general promotion of good health. Citrus fruits, such as oranges, lemons, and

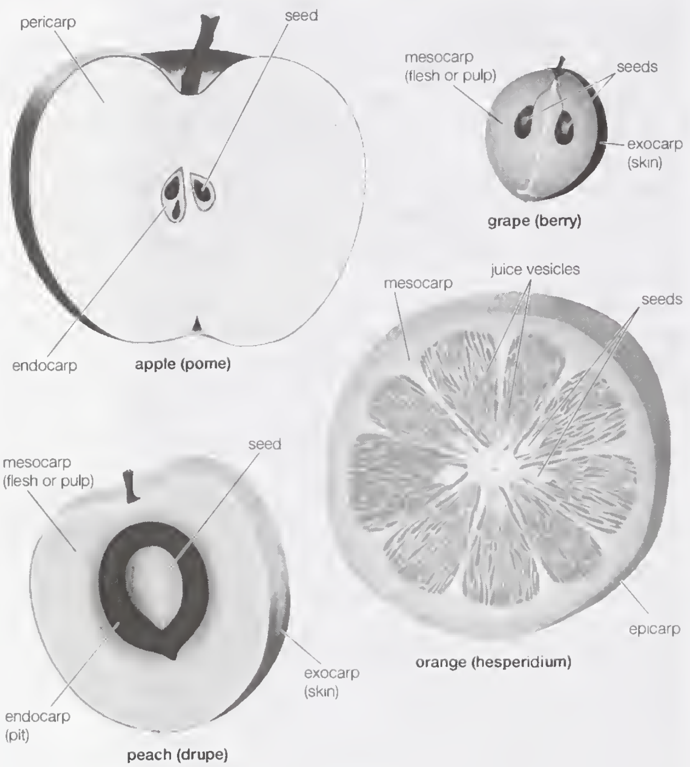

Figure 20: Four representative types of fruit.
Encyclopædia Britannica, Inc

grapefruits, are well known for their vitamin C content. Other sources include most berries and melons. Carotene, a chemical common to fruit, is easily converted in the body to vitamin A; cantaloupes, peaches, and apricots are significant sources of this nutrient.

Carbohydrates. Typically, fruits are high in carbohydrates, although a large range is possible—between 2 and 40 percent, depending on the type of fruit and its maturity. Free sugars usually include fructose, glucose, and sucrose; other sugars may be present in smaller quantities.

A large portion of the carbohydrates present in fruits is fibre, which is not digested and passes through the digestive system. Fibre is usually made up of cellulose, hemicellulose, and pectic substances. A small amount of starch may also be present in fruit, but starches are typically converted to sugars during the ripening process.

Protein and fat content. A negligible quantity of protein is found in fruits, and they usually contain less than 1 percent fat. Fats are most typically associated with the waxy cuticle surface of the fruit skin. Exceptions to this rule are avocados and olives, the flesh of which may contain as much as 20 percent oil.

Maturation and spoilage. *Ripening and senescence.* Fruits are living biological entities that perform a number of metabolic functions. Two functions of particular importance in fruit processing are respiration (the breaking down of carbohydrates, giving off carbon dioxide and heat) and transpiration (the giving off of moisture). Once the fruit is harvested, respiration and transpiration continue, but only for as long as the fruit can draw on its own food reserves and moisture. It is this limited ability to continue vital metabolic functions that defines fruit as perishable.

Fruit development can generally be divided into three major stages: growth, maturation, and senescence. The period of growth generally involves cell division and enlargement, which accounts for the increasing size of the fruit. Maturation is usually reached just prior to the end of growth and may include flavour development and increase in sugar content (detectable as increasing sweetness). Senescence is the period when chemical synthesizing pathways give way to degradative processes, leading to aging and death of tissue. Fruit ripening is thus the result of many complex changes, some interactive but many independent of one another.

Storage concerns. As harvested fruit ages, it is particularly important to manage the temperatures under which it is stored. For example, respiration largely involves enzymatic processes, which are significantly controlled by ambient temperature. The rate of chemical change in fruit generally doubles for every increase of 10° C (at room temperature, roughly 20° F).

Changes that take place during storage as fruit begins to overripen may include extreme colour formation, development of strong off-flavours with intense aroma, softening of the flesh, onset of physiological disorders, and manifestations of disease. In addition, fruit can be injured by overcooling. Chilling injury may be manifested by pitting and browning of the surface and by pitting and darkening of the flesh.

Microorganisms can also cause problems during senescence and storage. Many bacteria and fungi, for instance, are involved in decay after harvest. Typical fungi include *Alternaria, Botrytis, Monilinia, Penicillium,* and *Rhizopus.* These fungi are generally weak pathogens, in that they usually invest only weak or damaged fruit. Efforts to control infection begin in the orchard, usually with the application of fungicides. Cooling of the fruit or, conversely, hot-water dipping may also enhance storage quality. In addition, the careful application of ionizing radiation has been shown to inhibit microbial growth.

FRESH FRUIT

Storage. Once harvested, fruits are moved to storage. In the case of highly heat-sensitive products such as raspberries or cherries, the fruit should be precooled prior to storage. Precooling can be accomplished by hydrocooling (immersion of the fruit in cold water) or vacuum cooling (moistening and then placing under vacuum in order to induce evaporative cooling).

Controlled-atmosphere storage

A typical storage system for fruit is cold storage, using refrigerated air. Other techniques include controlled-atmosphere (CA) storage and hypobaric storage. In CA storage the oxygen and carbon dioxide content of the storage environment are controlled in such a way as to retard senescence and further deterioration of the fruit. In gen-

Table 4: Nutrient Composition of Selected Fruits and Fruit Products (per 100 grams)*

fruit or fruit product	energy (kcal)	water (g)	carbohydrate (g)	vitamin C (mg)	thiamine (mg)	riboflavin (mg)	niacin (mg)	vitamin A (IU)	fat (g)	protein (g)

eral, oxygen levels are reduced and carbon dioxide levels increased. CA conditions can be generated in a number of ways. Conventional CA depends on the respiration of the fruit to generate carbon dioxide, and the concentration of this gas is controlled by wet scrubbers, hydrated lime, or other commercial carbon dioxide removal systems. Liquid nitrogen and compressed nitrogen gas have also been used to flush out the ambient air of the storage facility. In other systems oxygen is converted to carbon dioxide by reaction with liquid propane or by catalytic burning.

Hypobaric storage involves the cold storage of fruit under partial vacuum. Typical conditions include pressures as low as 80 and 40 millimetres of mercury and temperatures of 5° C (40° F). Hypobaric conditions reduce ethylene production and respiration rates; the result is an extraordinarily high-quality fruit even after months of storage.

Packaging. Packaging systems for fresh fruit usually involve a simple plastic breathable bag or overwrap. However, as the market value of high-quality fruit has increased, so too have efforts to develop improved packaging. These efforts have been primarily in the area of modified-atmosphere packaging (MAP). In this type of packaging the barrier properties of the material are carefully selected according to the respiration characteristics of the fruit. The goal is to allow an exchange of gases and moisture that produces the optimal storage environment. Continued work in this field is producing "smart" films, which not only produce the optimal atmosphere for storage but also change their barrier properties depending on the ambient temperature and on the respiration rate of the fruit.

FRUIT JUICE

After fresh fruit, one of the most common fruit products is fruit juice. Fruit juice can take on many forms, including a natural-style cloudy product, a "nectar"-type product containing suspended solids, a fully clarified juice, juice concentrate, and fruit drinks.

The processing of fruit juice involves washing, extraction, clarification, and preservation.

Washing. Fruit is usually washed prior to any processing. Washing is typically conducted with a high-pressure soak or spray system. Under some conditions a surfactant or detergent may be added in order to release stubborn soil attached to the fruit. In apple processing a high-quality wash is necessary to ensure the safe removal of microorganisms responsible for mycotoxin formation and possible gastrointestinal poisoning.

Juice extraction. *Preparation.* Fruit is prepared for juice extraction by removing unwanted parts. This may include pitting operations for stone fruit such as apricots, cherries, or plums or peeling for such fruits as pineapples. In one large class of fruit, citrus fruit, juice extraction and separation from the peel are combined. Two major juice extraction systems for citrus exist. One is a reaming technique, in which the fruit is cut in half and the individual halves reamed to extract both the juice and the inner fruit solids. In the second major system, a hole is punched in the fruit and the juice squeezed out at the same time.

If the entire fruit is to be used in the juice, then typically it is disintegrated in a drum grater or a hammer mill. Care must be taken to control disintegration so that the particle size of the mash is compatible with the press system.

Rack-and-frame press

Pressing. Many different types of press are used for juice extraction. The most traditional is a rack-and-frame press, in which ground fruit (mash) is pumped into cloth partitions, called cheeses, which are separated by wooden or metallic racks. After a stack of cheeses has been produced, the press is activated and the juice expressed from the assembly.

Many variations of the rack-and-frame press exist. These include the continuous belt press, the bladder press, and the basket press.

Liquefaction. As an alternative to press systems, some processors have gone to total enzymatic liquefaction of the fruit mash. Cellulase and pectinase enzymes are added, and the mash is heated in order to accelerate the enzyme's performance.

Clarification. *Pectinization.* If the juice is to be clarified further or concentrated after extraction, treatment with pectinase may be required. The juice is monitored for pectin content using a qualitative pectin check, consisting of combining one part juice with two parts ethanol. If a gel forms, pectin is still present and depectinization must continue. When depectinization is complete, a floc is typically formed by the aggregation of partially degraded pectin-protein aggregates.

Filtration. Filtration systems are varied in design, operation, and application. The most traditional system is diatomaceous earth (DE) filtration, in which DE is used to aggregate and collect suspended solids. The DE is collected on filter paper inside the pressure filter as the juice passes through the unit. The resulting juice is sparkling clear. Owing to concern over the cost of DE and its disposal, other filtration processes have been designed. The most successful is membrane filtration, in which hollow fibre, open tubular, or ceramic membranes are employed in juice filtration systems.

Preservation. Once the juice has been clarified, it is ready to be preserved. In some cases large reserves of single-strength juice are kept in juice silos after having been pasteurized, but usually the juice is immediately processed into retail or institutional packages. For a single-strength juice packaging line, a typical process is to heat the juice to 88° C (190° F) and then bottle it. This produces a shelf-stable product.

For producing concentrate, the juice is passed through an evaporator, where the level of soluble solids is typically brought to 70 percent by weight. Retail packages of concentrate are typically filled at 45 percent dissolved solids; at this concentration a three-to-one dilution by the consumer will create a finished product with a soluble solid level of approximately 12 percent.

FRUIT PRESERVES, JAMS, AND JELLIES

The making of jellies and other preserves is an old and popular process, providing a means of keeping fruits far beyond their normal storage life and sometimes making use of blemished or off-grade fruits that may not be ideal for fresh consumption. In jelly making, the goal is to produce a clear, brilliant gel from the juice of a chosen fruit. Jams are made from the entire fruit, including the pulp, while preserves are essentially jellies that contain whole or large pieces. Marmalade, usually made from citrus fruit, is a jellylike concentrate of prepared juice and sliced peel.

Sugar, acid, and pectin

The essential ingredients for a successful preserve are sugar, acid, and pectin. These three ingredients lower the pH of the preserve and bind available water, thus creating an environment in which the growth of microorganisms is retarded. In some cases the fruit can provide all the pectin and acid that are needed. If the acid content of the fruit is low, external sources such as lemon juice can be added. Similarly, if the planned mix of fruit is low in pectin, a commercial source may be used. Sugar is always added, and in general all of the three essential ingredients have to be added in order to create a successful product.

The making of preserves begins with an initial mix containing not less than 45 parts by weight fruit for every 55 parts by weight sugar solids. The sugar solids are added after the fruit is crushed, and the mix is then cooked. Cooking may be done in a highly controlled vacuum kettle, in which flavour volatiles are captured and returned to the product. The cooking process continues until the heated mix is concentrated to a predetermined level of soluble solids. A generally accepted level is 65 percent soluble solids; at this concentration the boiling temperature is 7° to 12° above the boiling point of water. The product is then transferred to containers and sealed as a shelf-stable product.

The exact amount of sugar needed depends on the acidity level, the natural sugar content, and the type of product desired. If sugar content is too low, the resulting jelly will be tough; excessive sugar, on the other hand, will create a "soft set" that can be broken easily. Appropriate amounts of acid and pectin are added during the cooking process. The pH must be adjusted to an acidic level of approximately 3.1. Increased acidity reduces the amount of sugar needed in the blend, although excessive acidity can cause syneresis, or a separation of liquid from the gel.

If the pectin level is inadequate, then the preserve will not "set"; that is, not enough water will be bound to create a complete gel.

FRUIT PRESERVATION

Since fruits are generally acidic, they are naturally amenable to preservation. The premier role of acidity in preservation is to stop bacterial growth. Second, increased acidity can activate chemical reactions such as pectin set, which lowers water activity and reduces the possibility of microbial growth.

Dehydration. Dehydration is among the oldest and most common forms of fruit preservation. In dehydration, moisture in the fruit is driven off, leaving a stable food that has a moisture content below that at which microorganisms can grow. There are three basic systems for dehydration: sun drying, such as that used for raisins; hot-air dehydration; and freeze-drying.

Advantages

Dehydration has a number of advantages. Dehydrated fruit has a virtually unlimited shelf life when held under proper storage conditions. Drying does not significantly reduce the calories or minerals, and vitamin losses are similar to other preservation methods. In addition, by reducing the weight and the need for refrigeration, handling and transportation costs can be reduced dramatically. Dehydrated fruits are typically reduced in weight by 75 to 90 percent.

Encyclopædia Britannica, Inc.

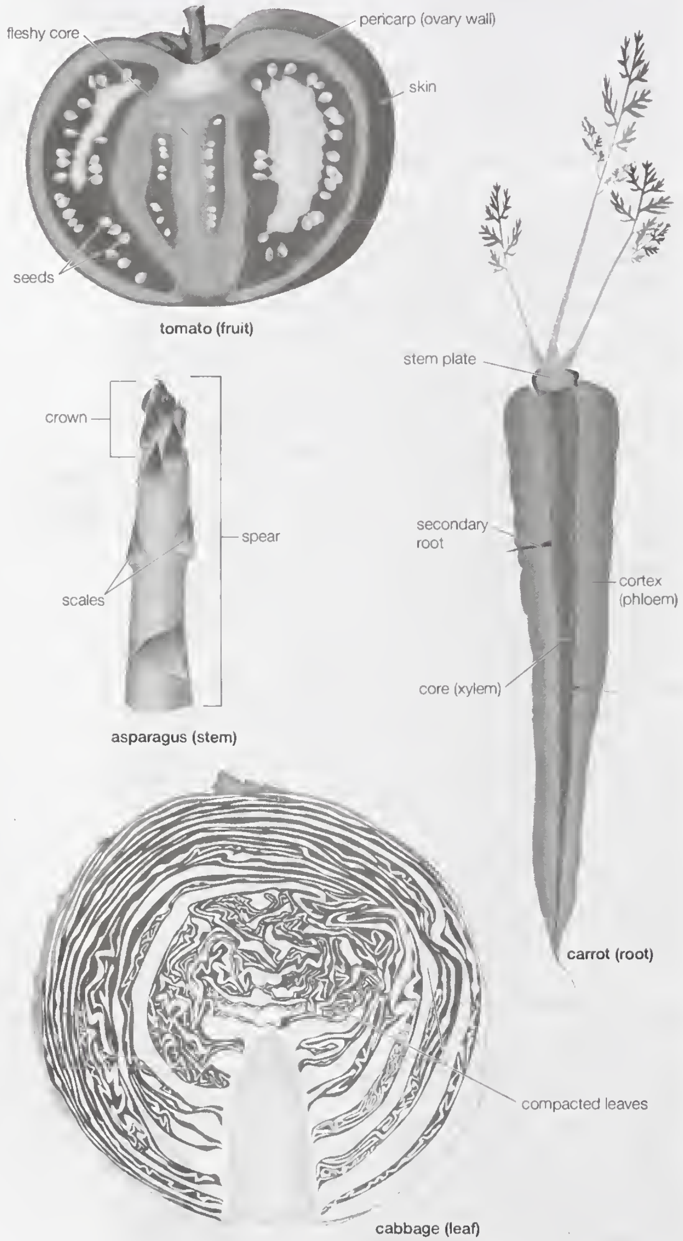

Figure 21: Structures of four representative vegetables.

Although dehydration offers a convenient product form, it usually requires a careful inactivation of enzymes. This is usually accomplished by blanching of the fruit or by chemical inactivation. Typically, sulfur dioxide is added for its antioxidant and preservative effects. In order to control browning, the fruit is often treated prior to dehydration with sodium sulfite and sodium bisulfite.

Thermal processes. In thermal processing, heat is used to destroy spoilage organisms and to inactivate troublesome enzymes. Enzymes are typically responsible for browning, softening, and the development of off-flavours. For high-acid fruit products the most typical thermal process is canning, in which fruit or fruit products are hot-filled or heated in a hermetically sealed container. The process temperature is generally in the range of 88° C (190° F).

Chemical preservation. Chemicals also can be used as a preservative, either through artificial addition or through the action of microorganisms. An example of the latter method is yeast fermentation, which can cause an increase in ethyl alcohol sufficient to preserve the fruit product. Pickling is another example of chemical preservation. In the case of pickling, the product may be preserved by the addition of salt, sugar, acetic acid (vinegar), and alcohol. High sugar content also acts as a fruit preservative by tying up all available moisture so that microorganisms cannot grow.

Irradiation. Although irradiation is an expensive method, it has been shown to be an effective means of extending the shelf life of fresh fruits. Irradiated fruit products have not been well received by the public, even in light of evidence supporting the healthfulness and safety of such foods.

Freezing. Freezing of fruits and fruit products is a common consumer practice. Cold temperatures act to retard the spoilage of fruit by inhibiting microbial action and slowing metabolic processes. In order to achieve extended storage life, the product must be held well below the freezing point of water—typically at a minimum of −23° C (−10° F). Generally, rapid freezing leads to an improved texture upon thawing.

A prerequisite for effective freezing is inactivation of fruit enzymes. Traditionally, this is done through blanching or by the addition of a chemical. Blanching consists of heating the fruit for a short time in water or steam prior to cooling and subsequent freezing. The blanch step is intended to inactivate enzyme systems responsible for off-flavours, browning, and softening. (M.R.McL.)

Vegetables

Vegetables consist of a large group of plants consumed as food. Perishable when fresh but able to be preserved by a number of processing methods, they are excellent sources of certain minerals and vitamins and are often the main source of dietary fibre. The consumption of vegetables has increased significantly as consumers have become more health-conscious. Owing to the perishable nature of the fresh produce, international trade in vegetables is mostly confined to the processed forms.

STRUCTURE AND COMPOSITION

Vegetables can be classified by edible parts into root (*e.g.,* potatoes and carrots), stem (asparagus and celery), leaf (lettuce and spinach), immature flower bud (broccoli and brussels sprouts), and fruit (tomatoes and cucumbers). The four basic types are illustrated in Figure 21.

Aging and spoilage. Depending on the class of vegetable, there are differences in the structure, size, shape, and rigidity of the individual cells. The fresh market shelf life and processing requirements are also very different. Vegetable cells, as plant cells, have rigid cell walls and are glued together by various polysaccharides such as cellulose, hemicellulose, and pectin. Once vegetables are harvested from the fields, the cells, now deprived of nutrient supplies normally obtained from soils and the air, go into senes-

Enzymatic reactions

cence, or aging. The most noticeable structural change in senescent vegetables is softening, or loss of texture. Softening is caused by natural enzymatic reactions that degrade the plant cell walls. A large group of enzymes is involved in the senescence stage, including cellulase, pectinase, hemicellulase, proteinase, and others. After these enzymes break open the cells, chemical oxidation reactions take place and the vegetables develop off-flavours and loss of nutritional value. Broken cells are also much more easily subject to microbial attacks, which quickly lead to spoilage. In addition, even though the vegetables may be packaged or bagged, the plant cells continue to respire, or break down carbohydrates for energy needs. Respiration leads to loss of quality, so that eventually the products are unsuitable for human consumption.

Nutritional value. The four quality factors of vegetables are colour, texture, flavour, and nutritive values. Fresh vegetables are purchased on the basis of colour and texture, but repeated purchases are made on the basis of flavour and nutritional content. The major nutrients contributed by vegetables to the human diet are dietary fibre (both soluble and insoluble), minerals (calcium, phosphorus, iron, sodium, potassium), and vitamins (vitamin C, vitamin A, thiamine, niacin, folic acid). The nutrient composition of selected vegetables is shown in Table 5.

Certain vegetables contribute lipids to the diet, mostly in the form of unsaturated oils. Roots and legumes can be important contributors of dietary proteins—especially in developing countries, where animal proteins are scarce. One potential nutritional problem of obtaining proteins from a single vegetable source is the low concentration of essential amino acids in vegetables. Twenty common amino acids are considered to be building blocks of proteins for the body. Of these 20, the body cannot synthesize eight; these eight must be obtained from foods. Most vegetable proteins are low in one of the eight essential amino acids; for example, corn is low in lysine, and soybeans are low in methionine. However, if proteins are obtained from a proper mixture of vegetables, there will not be a nutritional problem.

It is a common misconception that fresh vegetables are always superior in nutritional value to processed vegetables. Several investigations have shown frozen or canned vegetables can actually have higher nutritional value than fresh products. Fresh vegetables are subject to quality and vitamin losses during transportation and storage, whereas processing before these losses occur can yield a nutritionally superior product. Research has shown that a major cause of nutrient loss in vegetables is in the draining of cooking or processing liquids.

FRESH AND MINIMALLY PROCESSED VEGETABLES

Harvesting and storing. Most leafy vegetables that do not require harvesting by mechanical device are cooled immediately after harvest to remove field heat, sorted to remove debris, washed to remove dirt, and bundled or packed for shipping and retail. In most cases vegetables are bundled as whole plants, since cutting will injure the cells and liberate ethylene, which promotes senescence and shortens shelf life. Low-temperature storage is essential in the handling of quality leafy vegetables. On the other hand, storing below refrigerated temperature may lead to chilling injury of certain vegetables and to rapid loss of quality. In developing countries where refrigeration is not available, postharvest losses of fresh vegetables can be as much as half the total harvest.

For roots and legumes, the harvesting of which is normally done by machines, some sorting and grading are performed either in the field or at collection stations. Bulk handling of these vegetables is common, and few additional steps of preparation are performed before distribution. For vegetables that need to be stored for long periods of time, treatments to avoid microbial spoilage, insects, and small-animal invasion may be necessary. For some vegetables such as cucumbers, a washing and waxing step may be taken to improve the shelf life and the attractiveness of the produce.

Packaging. Provided in response to demands for convenient foods, minimally processed fresh produce has gained popularity in the marketplace. These vegetables go through additional preparation steps of washing, sorting, grading, cutting, and packaging into retail-size containers. In order to extend the shelf life of these products, vacuum packing and modified-atmosphere (MA) packaging are practiced. In most cases air is replaced by an atmosphere high in carbon dioxide and low in oxygen. This modified atmosphere can slow the respiration rate and therefore the senescence of cut vegetables. The most common products in American and European markets are various types of cut lettuces with shredded carrots, cabbages, and other vegetables. Modern packaging techniques employing "clean room" concepts make it possible for such vegetable products as salad mix and stir-fry mix to have shelf lives approaching those of the whole plants. The products can be shipped by refrigerated containers to overseas locations and still have a shelf life long enough to reach consumers.

Modified-atmosphere packaging

Minimally processed vegetables normally do not contain any preservatives and have not gone through any heat or chemical treatment. The disadvantage of these products is that refrigeration storage is essential, limiting its practice to developed countries.

PROCESSING OF VEGETABLES

Because of the varied growing and harvesting seasons of different vegetables at different locations, the availability of fresh vegetables differs greatly in different parts of the world. Processing can transform vegetables from perishable produce into stable foods with long shelf lives and thereby aid in the global transportation and distribution of many varieties of vegetables. The goal of processing is to deter microbial spoilage and natural physiological deterioration of the plant cells. Generally, the techniques include blanching, dehydrating, canning, freezing, fermenting and pickling, and irradiating.

Table 5: Nutrient Composition of Selected Vegetables and Vegetable Products (per 100 grams)*

vegetable or vegetable product	energy (kcal)	water (g)	carbohydrate (g)	vitamin C (mg)	thiamine (mg)	riboflavin (mg)	niacin (mg)	vitamin A (IU)	fat (g)	protein (g)
Asparagus, raw	23	92.40	4.54	13.2	0.140	0.128	1.170	583	0.20	2.28

Blanching. After vegetables have been washed clean, they must undergo blanching (heating) in hot water at 88° C (190° F) for two to five minutes or with steam in a conveyor at 100° C (212° F) for one-half to one minute. Blanching inactivates natural enzymes that would cause discoloration and off-flavours and aromas. It also serves to reduce the number of microorganisms and to render vegetables limp for easy packing into containers. For some vegetables, such as spinach, snap beans, and collards, the blanching step also serves to remove harsh flavours.

After blanching the vegetables must go through rapid cooling in either cold water or cold air for better quality retention. The vegetables are then ready for the various food-processing methods described below.

Dehydration. Drying is probably the oldest method of preserving foods. The removal of water from vegetables is accomplished primarily by applying heat, whether it be through the radiant energy of the sun or through air heated by electrical energy. A major advantage of removing water is a reduction in volume and weight, which aids in storage and transportation of the dried products. Modern drying techniques are very sophisticated. Many machines are available to perform tunnel drying, vacuum drying, drum drying, spray drying, and freeze-drying. Although freeze-drying produces a food of outstanding quality, the cost is high, and it has not been used widely in vegetable products.

Dehydrated potatoes

One of the most familiar dehydrated products is instant potatoes. Almost all the mashed potato dishes served in restaurants and institutions are rehydrated instant potatoes. In restaurants and institutions dehydrated potato granules are used, while dehydrated flakes are preferred for home cooking. Potato granules have high bulk density and are easy to handle in large quantity. However, they produce mashed potatoes with a pasty texture—an effect caused by the rupture of cells during processing, so that starch is released from the cells. Mashed potatoes made from flakes, on the other hand, have a mealy texture comparable to that of freshly prepared mashed potatoes. The major difference in the processing of these two dehydrated products is in the drying steps. For granules, air-lift drying is used to bring the product to 10–13 percent moisture. After screening to proper granule size, the product is dried to 6 percent moisture in a fluidized-bed drier. In the making of flakes, a steam-heated drum drier is used to bring a flattened sheet of potato solids to final moisture content before it is broken into a suitable size for packaging. Although a considerable quantity of the potato cells are ruptured during the breaking of the dried sheet, the reconstituted product has an acceptably mealy texture because the potatoes are subjected to a precooking and cooling treatment as well as the addition of a monoglyceride emulsifier.

A small amount of sulfite may be used in producing certain dried vegetables. The sulfite serves as an antimicrobial agent, aids in heat transfer, and (in the case of potatoes) acts as a blanching agent. A small percentage of the consumer population is allergic to sulfite. Although the rehydrated product contains little or no sulfite, consumer concerns are forcing the industry to search for economically feasible sulfite replacements.

Storage of canned vegetables

Canning. Putting foods into metal cans or glass jars is the major food-processing method of the world. It is particularly useful in developing countries where refrigeration is limited or nonexistent. In the canning process, vegetables are often cut into pieces, packed in cans, and put through severe heat treatment to ensure the destruction of bacteria spores. The containers are sealed while hot so as to create a vacuum inside when they are cooled to room temperature. Properly processed canned vegetables can be stored at room temperature for ycars. Minor defects of the process, however, will result in bulged cans after long periods of storage. For safcty reasons, the contents of these cans should not be consumed. Although in most cases bulged cans are causcd by the formation of gas from chemical reactions between the mctal cans and their acidic contents, there is a remote possibility that inadequate heat processing did not destroy all bacteria spores. And, even though most heat-resistant spores are nonpathogenic, spores of *Clostridium botulinum* can survive undcrprocessing and produce deadly toxins that cause botulism.

Unfortunately, because of the severe heat treatment, some canned vegetables can have inferior quality and less nutritive value than fresh and frozen products. The nutrient most susceptible to destruction in canning is vitamin C.

For high-quality products, aseptic canning is practiced. Also known as high-temperature–short-time (HTST) processing, aseptic canning is a process whereby presterilized containers are filled with a sterilized and cooled product and sealed in a sterile atmosphere with a sterile cover. The process avoids the slow heat penetration inherent in the traditional in-container heating process, thus creating products of superior quality.

The canning process can be illustrated by the example of green beans (*Phaseolus vulgaris L.*). After arrival at the processing plant, the beans are conveyed to size graders. Graders consist of revolving cylinders with slots of various diameters through which the beans fall onto conveyers. The conveyers carry them to snipping machines, where their tips and stems are cut off. The snipped beans then pass over inspection belts, where defective beans are removed. Smaller beans are canned as whole beans, while larger beans are cut crosswise by machine into various lengths. Some smaller beans are cut lengthwise and marketed as French-cut beans. Both the small whole and cut beans are blanched for 1½ to 2 minutes in 82° C (150° F) water and mechanically packed in cans. The cans are then filled with hot water and dry salt or with brine, steam-exhausted for approximately five minutes, and sealed while hot or with steam flow. Depending on the size of the can, they are heat-processed for various periods of time—from 12 minutes at 120° C (250° F) to 36 minutes at 115° C (240° F). The cans are cooled to room temperature, labeled, and packaged for storage or immediate distribution.

Individually quick-frozen method

Freezing. Frozen foods have outstanding quality and nutritive value. Indeed, some frozen vegetables, such as green peas and sweet corn, may be superior in flavour to fresh produce. The high quality of frozen foods is mainly due to the development of a technology known as the individually quick-frozen (IQF) method. IQF is a method that does not allow large ice crystals to form in vegetable cells. Also, since each piece is individually frozen, particles do not cohere, and the final product is not frozen into a solid block. Various freezing techniques are commonly used in the preservation of vegetables. These include blast freezing, plate freezing, belt-tunnel freezing, fluidized-bed freezing, cryogenic freezing, and dehydrofreezing. The choice of method depends on the quality of end product desired, the kind of vegetable to be frozen, capital limitations, and whether or not the products are to be stored as bulk or as individual retail packages.

Most vegetables frozen commercially are intended for direct consumer use or for further processing into soups, prepared meals, or specialty items. Advances in packaging materials and techniques have led to bulk frozen products being stored in large retortable pouches. Many restaurants and institutions prefer bulk frozen soups packaged in these pouches because of their quality and convenience.

One of the most important vegetable crops preserved by freezing is sweet corn (*Zea mays L.*). Both corn on the cob and cut corn are frozen. Sweet corn must be harvested while still young and tender and while the kernels are full of "milk." After the ears are mechanically harvested, they are promptly hauled to the processing plant, where they are automatically dehusked and desilked. Probably more than any other vegetable, sweet corn loses its quality rapidly after harvest. Frozen corn maintains high quality by being processed within a few hours of picking. Corn on the cob is a particularly difficult vegetable to freeze. The dehusked and desilked ears are thoroughly washed and blanched in steam for 6 to 11 minutes and then promptly cooled. However, even an 11-minute blanch in steam does not completely inactivate all the enzymes in the cob portion. It is believed that the off-flavour frequently found in home-frozen corn on the cob comes from off-flavours produced in the cob that migrate out to the kernels. Blanched and cooled corn is quickly frozen by the fluidized-bed freezing process before packing. Blanched whole-kernel corn is produced either by blanching the corn on the cob before cutting; by partially blanching on the cob to set the milk, then cutting and blanching again; or by cutting before blanching. The "split" method of blanching twice produces the highest-quality product. After the corn is cut, impurities such as husk, silk, and imperfect kernels must be removed by either brine flotation or froth washing. In both methods the sound corn stays at the bottom while the impurities float off the tank. Whole-kernel corn can be frozen quickly using the individually quick-frozen method. Frozen corn can be packaged into polyethylene bags or cardboard cartons and labeled for retail, or it can be bulk-stored for further processing into components of value-added products such as frozen dinners.

Fermentation and pickling. In both fermented and pickled vegetables, acid is used to preserve the products. Pickled vegetables include cucumbers, green tomatoes, onions, radishes, and cabbages. The variety of vegetables used for fermentation or pickling may not be the same as fresh market vegetables. Owing to the acid environment, fermented or pickled vegetables need less heat treatment before being placed in containers.

Irradiation. Ionizing radiation, mostly gamma-ray, has been used in several countries to preserve vegetables. The practice is quite common in preventing potatoes from sprouting during long-term storage. Despite studies showing that products treated with low-dose ionizing radiation are safe, consumers are still concerned about this processing technology and have not accepted it. (Jo.J.J.)

Fish

Finfish, mollusks, and crustaceans

The word fish is commonly used to describe all forms of edible finfish, mollusks (*e.g.,* clams and oysters), and crustaceans (*e.g.,* crabs and lobsters) that inhabit an aquatic environment. Fish from the marine and freshwater bodies of the world have been a major source of food for humankind since before recorded history. Harvesting wild fish from fresh and marine waters and raising cultured fish in ponds were practices of ancient Egyptians, Greeks, and other Mediterranean peoples. Rudimentary processing techniques such as sun-drying, salting, and smoking were used by these ancient groups to stabilize the fish supply. Modern methods of processing and preservation have encouraged the consumption of many species of fish that are popular throughout the world.

CHARACTERISTICS OF FISH

Structure of skeletal muscles. The majority of edible fish products are derived from the skeletal muscles (flesh), which represent more than 50 percent of the total body mass of these animals. The skeletal muscles of fish differ from those of mammals and birds in that they are largely composed of stacks of short bundles of muscle fibres called myomeres. The myomeres are separated by thin horizontal (myosepta) and vertical (myocommata) layers of connective tissue. The unique structure and thin connective tissue sheaths of fish muscle give the meat its characteristic soft, flaky texture.

The skeletal muscles of fish are composed mostly of white, fast-twitch fibres. The high percentage of white fibres allows fish to swim with sudden, rapid movements and gives the meat its white colour. These fibres primarily metabolize glucose, a simple sugar released from muscle glycogen stores, for energy production through anaerobic (*i.e.,* in the absence of oxygen) glycolysis. Therefore, white fibres contain relatively little myoglobin, the oxygen-binding protein that provides the red colour of muscles in other animals.

Nutrient composition. The composition of fish may vary considerably—especially in their fat content—during certain growth periods and annual spawning or migration periods. In addition, the composition of fish bred in captivity (*i.e.,* aquaculture fish) may vary according to their artificial diet. Table 6 shows the nutrient composition of several types of fish.

Proteins. Fish are an excellent source of high-quality protein. Mollusks are generally lower in protein compared with finfish and crustaceans because of their high water content. The proteins found in fish are essentially the same as those found in the meat derived from other animals—that is, the sarcoplasmic proteins (*e.g.,* enzymes and myoglobin), the contractile or myofibrillar proteins (*e.g.,* actin and myosin), and the connective tissue proteins (*i.e.,* collagen).

Fat. The fat in fish is mostly liquid (*i.e.,* fish oil), because it contains a relatively low percentage of saturated fatty acids. Fish belong in a special nutritional class because they contain the omega-3 polyunsaturated fatty acids—eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)—which have been shown to protect against several diseases, including heart disease. Unlike land plants, the marine and freshwater plants on which fish feed are rich in EPA and DHA.

Vitamins and minerals. Fish provide a number of important vitamins and minerals to the diet. They are a good source of the fat-soluble vitamins A, D, E, and K and the B vitamins riboflavin, niacin, and thiamine. The mineral content includes calcium, magnesium, phosphorus, and iron.

Microbial contamination

Microbiology. Because of their soft tissues and aquatic environment, fish are extremely susceptible to microbial contamination. At the time of harvest, fish carry a high microbial load on the surface of their skin, in their intestinal tract, and in their gills.

The type and number of microorganisms that live in fish vary according to the season, the species, and the natural habitat. Additional contamination may occur during the harvesting, handling, or processing of the fish. Common spoilage microorganisms of fish include species of *Pseudomonas, Moraxella,* and *Acinetobacter,* found mainly in marine fish, and *Bacillus* and *Micrococcus,* found in freshwater fish. Fish may also contain pathogenic (disease-causing) microorganisms such as *Salmonella* and *Escherichia coli.* Pathogenic contamination is of special

Table 6: Nutrient Composition of Raw Edible Portion of Fish Species (per 100 grams)

concern with mollusks because they are often eaten raw and as whole animals.

HANDLING OF HARVESTED FISH

The retention of nutritional properties and product quality of fish is dependent on proper handling of the catch after it has been harvested from its aquatic environment.

Chilling. Harvested fish must be immediately stored in a low-temperature environment such as ice or refrigerated seawater. This chilling process slows the growth of microorganisms that live in fish and inhibits the activity of enzymes. Because fish have a lower body temperature, softer texture, and less connective tissue than land animals, they are much more susceptible to microbial contamination and structural degradation. If immediate chilling is not possible, then the fish must generally be sold and eaten on the day of the harvest.

Ice cooling and holding normally requires a one-to-one or one-to-two weight ratio of ice to fish, depending on the specific geographic location and the time it takes to transport the fish to the processing plant. Refrigerated seawater cooling and holding causes less bruising and other structural damage to the fish carcasses than ice cooling. However, fish cooled in refrigerated seawater absorbs salt from the water. For this reason fish that is destined for sale on the fresh or frozen market may be held in refrigerated seawater for only a limited amount of time. The addition of salt during canning or smoking processes is adjusted in order to compensate for any absorbed salt.

Preprocessing. Preprocessing of fish prepares the raw material for final processing. It is often performed on shipboard or in a shore-based plant and includes such operations as inspection, washing, sorting, grading, and butchering of the harvested fish.

Butchering of fresh fish

The butchering of fish involves the removal of nonedible portions such as the viscera, head, tail, and fins (see Figure 22). Depending on the butchering process, as much as 30 to 70 percent of the fish may be discarded as waste or reduced to cheap animal feed. The lower figure applies when the fish is canned or sold as "whole." The higher figure applies when the fish is filleted or made into other pure meat products; in these cases the skeleton is discarded with as much as 50 percent of the edible flesh attached. Efforts to utilize this discarded fraction for the production of alternative food products have begun in the fish industry. (See below *Total utilization of raw materials.*)

FINAL PROCESSING OF FISH

The four basic procedures used in the final processing of fish products are heating, freezing, controlling water activity (by drying or adding chemicals), and irradiating. All these procedures increase the shelf life of the fish by inhibiting the mechanisms that promote spoilage and degradation. Each of these procedures also has an effect on the nutritional properties of the final product.

Heating. Heat treatment can significantly alter the quality and nutritional value of fish. Fish is exposed to heat during both the cooking process and the canning process.

Cooking. Fish is cooked in order to produce changes in the texture and flavour of the product and to kill pathogenic microorganisms. Heating fish to an internal temperature above 66° C or 150° F (*i.e.,* pasteurization conditions) is sufficient to kill the most resistant microorganisms. The cooking time must be closely regulated in order to prevent excessive loss of nutrients by heat degradation, oxidation, or leaching (the loss of water-soluble nutrients into the cooking liquid).

Canning. The canning process is a sterilization technique that kills microorganisms already present on the fish, prevents further microbial contamination, and inactivates degradative enzymes. In this process fish are hermetically sealed in containers and then heated to high temperatures for a given amount of time. Canned fish can be stored for several years. However, sterilization does not kill all microorganisms, and bacterial growth and gas production may occur if the products are stored at very high temperatures.

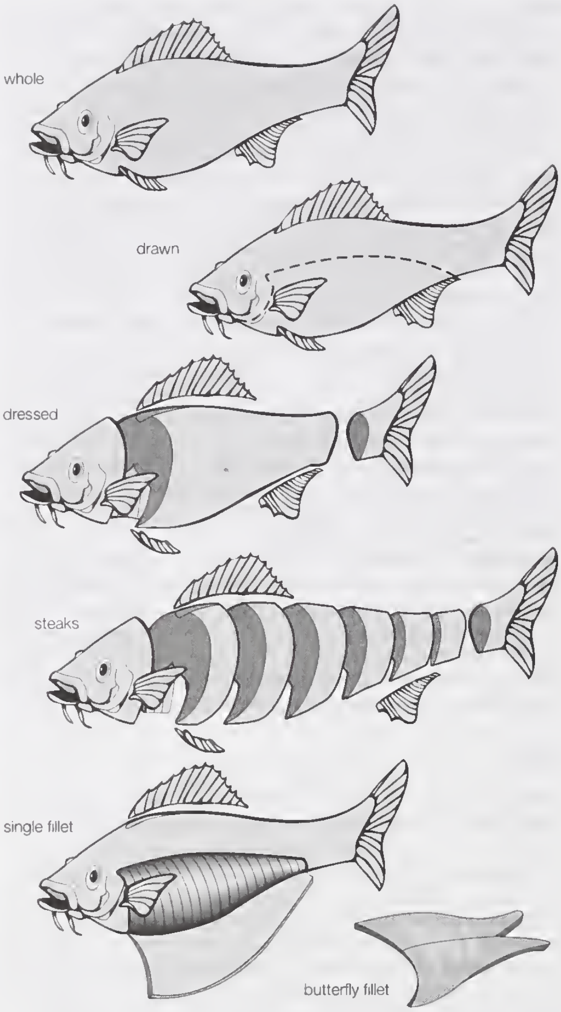

Figure 22: Schematic representation of various cuts of fish.
Encyclopædia Britannica, Inc

Because the severe thermal conditions of canning cause the disintegration and discoloration of the flesh of many species of fish, only a few types of fish are available as canned products. The most common types are tuna, salmon, herring, sardines, and shrimp. The thermal processing does not have a detrimental effect on the high-quality protein of the fish. In addition, these species are often canned with their bones left intact. The bones become soft and edible, significantly increasing the level of calcium present in the fish product. Tuna is an exception; because of special handling considerations, the bones of tuna are removed prior to canning. Tuna is normally caught far offshore and must be frozen and held for some period of time prior to canning. During this freezing and holding period unsaturated fatty acids are oxidized, causing the tuna to become rancid. The rancidity is removed by precooking, and the bones are removed at this time in order to facilitate the cutting and preparation of the meat for canning.

Canning of tuna

Freezing. Of the many processing methods used to preserve fish, only freezing can maintain the flavour and quality of fresh fish. Freezing greatly reduces or halts the biochemical reactions in fish flesh. For instance, in the absence of free water, enzymes cannot react to soften and degrade the flesh. The three steps for freezing fish include immediate cooling and holding, rapid freezing, and cold storage. If fish is frozen improperly, structural integrity may be compromised because of enzymatic degradation, texture changes, and dehydration.

Immediate cooling. The rapid cooling and holding of fish at temperatures between 2° and −2° C (36° and 28° F) takes place immediately after the fish have been harvested (see above *Handling of harvested fish: Chilling*).

Rapid freezing. The key to freezing is rapid reduction of the temperature to between −2° and −7° C (28° and 20° F). This temperature range represents the zone of maximum ice crystal formation in the cells of the flesh. If water in the cells freezes quickly, then the ice crystals will remain small and cause minimal damage to the cells. However, slow freezing results in the formation of large ice crystals and the rupturing of the cell membranes. When slow-frozen flesh is thawed, the ruptured cells release water (called drip) and many compounds that provide certain flavour characteristics of fish, resulting in a dry, tasteless product. Fish that passes through the zone of maximum ice crystal formation in less than one hour will generally have minimum drip loss upon thawing.

Cold storage. Once fish is frozen, it must be stored at a constant temperature of −23° C (−10° F) or below in order to maintain a long shelf life and ensure quality. A large portion of fresh fish is water (*e.g.,* oysters are more than 80 percent water). Because the water in fish contains many dissolved substances, it does not uniformly freeze at the freezing point of pure water. Instead, the free water in fish freezes over a wide range, beginning at approximately −2° C (28° F). The amount of remaining free water decreases until the product reaches a temperature of approximately −40° C (−40° F). Fish held below that temperature and packaged so as not to allow water loss through sublimation can be stored for an indefinite period. Unfortunately, there are relatively few commercial freezers capable of storing fish at −40° because of the tremendous variation in energy costs. Fish are therefore normally stored at −18° to −29° C (0° to −20° F), resulting in a variable shelf life ranging from a few weeks to almost one year.

Controlling water activity. Reducing the water activity of fish inhibits the growth of microorganisms and slows the chemical reactions that may be detrimental to the quality of the fish product. The control of water activity in fish is accomplished by drying, adding chemicals, or a combination of both methods.

Drying. The principal methods of drying, or dehydrating, fish are by forced-air drying, vacuum drying, or vacuum freeze-drying. Each of these methods involves adding heat to aid in the removal of water from the fish product. During the initial stages of drying, known as the constant-rate period, water is evaporated from the surface of the product and the temperature of the product remains constant. In the final stages of drying, known as the falling-rate period, the temperature of the product increases, causing water to move from the interior to the surface for evaporation.

Salt-curing

Curing. Curing reduces water activity through the addition of chemicals, such as salt, sugars, or acids. There are two main types of salt-curing used in the fish industry: dry salting and pickle-curing. In dry salting the butchered fish is split along the backbone and buried in salt (called a wet stack). Brine is drained off until the water content of the flesh is reduced to approximately 50 percent (the typical water content of fresh fish is 75 to 80 percent) and the salt content approaches 25 percent. In heavy or hard-cure salting, an additional step is taken in which warm air is forced over the surface of the fish until the water content is reduced to about 20 percent and the salt content is increased to approximately 30 percent. Most dry-salted fish products are consumed in warm, humid countries or in areas that have few means of holding products in refrigeration or cold storage.

In pickle-curing, fish are preserved in airtight barrels in a strong pickle solution formed by the dissolving of salt in the body fluids. This curing method is used for fatty fish such as herring.

Smoking. Traditionally, smoking was a combination of drying and adding chemicals from the smoke to the fish, thus preserving and adding flavour to the final product. However, much of the fish smoked today is exposed to smoke just long enough to provide the desired flavour with little, if any, drying. These products, called kippered fish, have short shelf lives, even under refrigeration, since the water activity remains high enough for spoilage organisms to grow.

The smoking process consists of soaking butchered fish in a 70 to 80 percent brine solution for a few hours to overnight, resulting in a 2 to 3 percent salt content in the fish. The fish are then partially dried on racks. As the brine on the surface dries, dissolved proteins produce a glossy appearance, which is one of the commercial criteria for quality. Smoking is carried out in kilns or forced-air smokehouses that expose the fish to smoke from smoldering wood or sawdust. In cold-smoking the temperature does not exceed 29° C (85° F), and the fish is not cooked during the process. Hot-smoking is more common and is designed to cook the fish as well as to smoke it.

Irradiating. Irradiation offers a means of pasteurizing or sterilizing a variety of food products. However, the use of this process has not been universally accepted throughout the food industry.

Food irradiators utilize radioisotopes, such as cobalt-60 (^{60}Co) or cesium-137 (^{137}Cs), or electron beam generators to provide a source of ionizing radiation. The irradiation of seafood has been extensively studied since the 1950s. The pasteurization of fresh fish using low-level dosages of ionizing radiation may extend the shelf life of the product up to several weeks. The sensory and nutritional characteristics of the fish are unaffected at these low levels of radiation.

TOTAL UTILIZATION OF RAW MATERIALS

In response to an increased demand for "ready-to-eat" fish products, along with a growing awareness of the limited supply of natural fish stocks, the fish industry has developed procedures for more efficient utilization of available raw materials. Because as much as 70 percent of harvested fish has traditionally been discarded or converted into cheap animal feeds, initial efforts to conserve fishery resources have focused on the development of edible products from underutilized species.

Gelling action of washed fish flesh

Surimi. *Surimi* was developed in Japan several centuries ago when it was discovered that washing minced fish flesh, followed by heating, resulted in a natural gelling of the flesh. When the *surimi* was combined with other ingredients, mixed or kneaded, and steamed, various fish gel products called *kamaboko* (fish cakes) were produced and sold as *neriseihin* (kneaded seafoods).

Modern *surimi* production consists of continuous operating lines with automated machinery for heading, gutting, and deboning of the fish; mincing, washing, and pressing (to remove water); and heating of the flesh. The *surimi* is then mixed with cryoprotectants and frozen for cold storage. Frozen *surimi* blocks are shipped to processing plants that produce various *kamaboko* products such as original *kamaboko* (*itatsuki*), broiled *kamaboko* (*chikuwa*), fried *kamaboko* (*satsumage*), and analog products, including imitation crab, scallops, and shrimp.

The chemistry of the *surimi* process involves the differential extraction of muscle proteins. The water-soluble sarcoplasmic proteins are removed during the washing of the minced flesh. These proteins inhibit the gelling properties of the minced flesh. The flesh is then comminuted with salt, which solubilizes the myofibrillar proteins actin and myosin. Upon heating, the myofibrillar proteins form a network structure that takes on a gellike consistency. Cryoprotectants are necessary to stabilize the myofibrillar protein network during frozen storage.

Minced fish flesh. The success of *surimi*-based products has stimulated the development of other products made from minced flesh. Minced fish products do not undergo the repeated washing cycles necessary for the production of *surimi.* Because of the presence of residual oils and sarcoplasmic enzymes (both oil and sarcoplasmic proteins are removed during the washing of *surimi*), cryoprotectants must also be added to the minced flesh prior to freezing in order to protect the product from oil oxidation and enzyme degradation.

Minced fish flesh is used in a wide variety of products. The largest volumes are extruded into formed patties for main dishes and sandwiches. The forming process involves combining the minced flesh with condiments and extruding the mix under pressure to produce the desired product, much like the formation of hamburger patties and sausages. The formed product may be battered and breaded in a final processing step. Other minced flesh products include nuggets and items used as hors d'oeuvres, fish chowders, and smoked fish sticks. (G.M.P.)

Meat

Meat is the common term used to describe the edible portion of animal tissues and any processed or manufactured products prepared from these tissues. Meats are often classified by the type of animal from which they are taken. Red meat refers to the meat taken from mammals; white meat refers to the meat taken from fowl; seafood refers to the meat taken from fish and shellfish; and game refers to meat taken from animals that are not commonly domesticated. In addition, most commonly consumed meats are specifically identified by the live animal from which they come. Beef refers to the meat from cattle, veal from calves, pork from hogs, lamb from young sheep, and mutton from sheep older than two years. It is with these latter types of red meat that this section is concerned.

CONVERSION OF MUSCLE TO MEAT

Muscle is the predominant component of most meat and meat products. Additional components include the connective tissue, fat (adipose tissue), nerves, and blood vessels that surround and are embedded within the muscles. The structural and biochemical properties of muscle are therefore critical factors that influence both the way animals are handled before, during, and after the slaughtering process and the quality of meat produced by the process.

Muscle structure and function. There are three distinct types of muscle in animals: smooth, cardiac, and skeletal. Smooth muscles, found in the organ systems including the digestive and reproductive tracts, are often used as casings for sausages. Cardiac muscles are located in the heart and are also often consumed as meat products. However, most meat and meat products are derived from skeletal muscles, which are usually attached to bones and, in the living animal, facilitate movement and support the weight of the body. Skeletal muscles are the focus of the following discussion.

Connective tissue

Skeletal muscle structure. Skeletal muscles are divided from one another by a covering of connective tissue called the epimysium. As shown in Figure 23, individual muscles are divided into separate sections (called muscle bundles) by another connective tissue sheath known as the perimysium. Clusters of fat cells, small blood vessels (capillaries), and nerve branches are found in the region between muscle bundles. Muscle bundles are further divided into smaller cylindrical muscle fibres (cells) of varying lengths that are individually wrapped with a thin connective tissue sheath called the endomysium. Each of the connective tissue sheaths found throughout skeletal muscle is composed of collagen, a structural protein that provides strength and support to the muscles.

The plasma membrane of a muscle cell, called the sarcolemma, separates the sarcoplasm (muscle cell cytoplasm) from the extracellular surroundings. Within the sarcoplasm of each individual muscle fibre are approximately 1,000 to 2,000 myofibrils. Composed of the contractile proteins actin and myosin, the myofibrils represent the smallest units of contraction in living muscle.

Skeletal muscle contraction. The contraction of skeletal muscles is an energy-requiring process. In order to perform the mechanical work of contraction, actin and myosin utilize the chemical energy of the molecule adenosine triphosphate (ATP). ATP is synthesized in muscle cells from the storage polysaccharide glycogen, a complex carbohydrate composed of hundreds of covalently linked molecules of glucose (a monosaccharide or simple carbohydrate). In a working muscle, glucose is released from the glycogen reserves and enters a metabolic pathway called glycolysis, a process in which glucose is broken down and the energy contained in its chemical bonds is harnessed for the synthesis of ATP. The net production of ATP depends on the level of oxygen reaching the muscle. In the absence of oxygen (anaerobic conditions), the products of glycolysis are converted to lactic acid, and relatively little ATP is produced. In the presence of oxygen (aerobic conditions), the products of glycolysis enter a second pathway, the citric acid cycle, and a large amount of ATP is synthesized by a process called oxidative phosphorylation.

In addition to carbohydrates, fats supply a significant amount of energy for working muscles. Fats are stored in the body as triglycerides (also called triacylglycerols). A triglyceride is composed of three fatty acid molecules (nonpolar hydrocarbon chains with a polar carboxyl group at one end) bound to a single glycerol molecule. If the fat deposits are required for energy production, fatty acids are released from the triglyceride molecules in a process called fatty acid mobilization. The fatty acids are broken down into smaller molecules that can enter the citric acid cycle for the synthesis of ATP by oxidative phosphorylation.

Therefore, the utilization of fats for energy requires the presence of oxygen.

Myoglobin

An important protein of muscle cells is the oxygen-binding protein myoglobin. Myoglobin takes up oxygen from the blood (transported by the related oxygen-binding protein hemoglobin) and stores it in the muscle cells for oxidative metabolism. The structure of myoglobin includes a nonprotein group called the heme ring. The heme ring consists of a porphyrin molecule bound to an iron (Fe) atom. The iron atom is responsible for the binding of oxygen to myoglobin and has two possible oxidation states: the reduced, ferrous form (Fe^{2+}) and the oxidized, ferric form (Fe^{3+}). In the Fe^{2+} state iron is able to bind oxygen (and other molecules). However, oxidation of the iron atom to the Fe^{3+} state prevents oxygen binding.

Postmortem muscle. Once the life of an animal ends, the life-sustaining processes slowly cease, causing significant changes in the postmortem (after death) muscle. These changes represent the conversion of muscle to meat.

pH changes. Normally, after death, muscle becomes more acidic (pH decreases). When an animal is bled after slaughter (a process known as exsanguination), oxygen is no longer available to the muscle cells, and anaerobic glycolysis becomes the only means of energy production available. As a result, glycogen stores are completely converted to lactic acid, which then begins to build up, causing the pH to drop. Typically, the pH declines from a physiological pH of approximately 7.2 in living muscle to a postmortem pH of approximately 5.5 in meat (called the ultimate pH).

Protein changes. When the energy reserves are depleted, the myofibrillar proteins, actin and myosin, lose their extendability, and the muscles become stiff. This condition is commonly referred to as rigor mortis. The time an animal requires to enter rigor mortis is highly dependent on the species (for instance, cattle and sheep take longer than hogs), the chilling rate of the carcass from normal body temperature (the process is slower at lower temperatures), and the amount of stress the animal experiences before slaughter.

Eventually the stiffness in the muscle tissues begins to decrease owing to the enzymatic breakdown of structural proteins (*i.e.*, collagen) that hold muscle fibres together. This phenomenon is known as resolution of rigor and can continue for weeks after slaughter in a process referred to as aging of meat. This aging effect produces meats that are more tender and palatable.

PROPERTIES OF MEAT

Chemistry and nutrient composition. Regardless of the animal, lean muscle usually consists of approximately 21 percent protein, 73 percent water, 5 percent fat, and 1 percent ash (the mineral component of muscle). These figures vary as an animal is fed and fattened. Generally, as fat increases, the percentages of protein and water decrease. Table 7 provides a comparison of the nutrient composition of many meat products.

Protein. Meat is an excellent source of protein. As is explained above, these proteins carry out specific functions in living muscle tissue and in the conversion of muscle to meat. They include actin and myosin (myofibrillar proteins), glycolytic enzymes and myoglobin (sarcoplasmic proteins), and collagen (connective tissue proteins). Because the proteins found in meat provide all nine essential amino acids to the diet, meat is considered a complete source of protein.

Fat. Fats, in the form of triglycerides, accumulate in the fat cells found in and around the muscles of the animal. Fat deposits that surround the muscles are called adipose tissue, while fat that is deposited between the fibres of a muscle is called marbling.

In the diet the fats found in meat act as carriers for the fat-soluble vitamins (A, D, E, and K) and supply essential fatty acids (fatty acids not supplied by the body). In addition to their role as an energy reserve, fatty acids are precursors in the synthesis of phospholipids, the main structural molecules of all biological membranes.

Saturated and unsaturated fatty acids

Fatty acids are classified as being either saturated (lacking double bonds between their carbon atoms), monounsaturated (with one double bond), or polyunsaturated (containing several double bonds). The fatty acid composition of meats is dependent on several factors. In animals with simple stomachs, called nonruminants (*e.g.*, pigs), diet can significantly alter the fatty acid composition of meat. If nonruminants are fed diets high in unsaturated fats, the fat they deposit in their muscles will have elevated levels of unsaturated fatty acids. In animals with multichambered stomachs, called ruminants (*e.g.*, cattle and sheep), fatty acid composition found in the lean muscle is relatively unaffected by diet because microorganisms in the stomach alter the chemical composition of the fatty acids before they leave the digestive tract.

A beneficial characteristic of saturated fatty acids is that they do not undergo oxidation when exposed to air. However, the double bonds found in unsaturated fatty acids are susceptible to oxidation, and this oxidation promotes rancidity in meat. Therefore, products higher in saturated fats can generally be stored for a longer time without developing unpleasant flavours and odours.

Vitamins and minerals. Meat contains a number of essential vitamins and minerals. It is an excellent source of many of the B vitamins, including thiamine, choline, B_6, niacin, and folic acid. Some types of meat, especially liver, also contain vitamins A, D, E, and K.

Meat is an excellent source of the minerals iron, zinc, and phosphorus. It also contains a number of essential trace minerals, including copper, molybdenum, nickel, selenium, chromium, and fluorine. Table 7 provides a comparison of the vitamin and mineral content of different types of meat.

Table 7: Nutrient Composition of Cooked Lean Red Meats (per 100 grams)

meat type and cut	energy (kcal)	water (g)	protein (g)	fat (g)	cholesterol (mg)	vitamin B_{12} (μg)	thiamine (mg)	iron (mg)	zinc (mg)

Source: *Composition of Foods*, Agriculture Handbook no. 8–10, 8–13, and 8–17, U.S. Department of Agriculture.

Cholesterol. Cholesterol is a constituent of cell membranes and is present in all animal tissues. Leaner meats typically are lower in cholesterol. Veal, however, is an exception: it is lower in fat than mature beef but has significantly higher cholesterol levels.

Carbohydrates. Meat contains virtually no carbohydrates. This is because the principal carbohydrate found in muscle, the complex sugar glycogen, is broken down in the conversion of muscle to meat (see above *Postmortem muscle: pH changes*). Liver is an exception, containing up to 8 percent carbohydrates.

Water. Water is the most abundant component of meat. However, because adipose tissue contains little or no moisture, as the percentage of fat increases in a meat cut, the percentage of water declines. Therefore, lean young veal may be as much as 80 percent water, while fully fattened beef may be as little as 50 percent. Because water is lost when meats are cooked, the percentages of protein and fat in cooked meats are usually higher than in their raw counterparts.

Colour. In well-bled animals approximately 80 to 90 percent of the total meat pigment is due to the oxygen-binding protein myoglobin. Colour differences in meat are related to the myoglobin content of muscle fibres and to the chemical state of the iron atom found in the myoglobin molecule.

White fibres and red fibres

Myoglobin content. A number of factors influence the myoglobin content of skeletal muscles. Muscles are a mixture of two different types of muscle fibre, fast-twitch and slow-twitch, which vary in proportions between muscles. Fast-twitch fibres have a low myoglobin content and are therefore also called white fibres. They are dependent on anaerobic glycolysis for energy production. Slow-twitch fibres have a high amount of myoglobin and a greater capacity for oxidative metabolism. These fibres are often called red fibres. Therefore, dark meat colour is a result of a relatively high concentration of slow-twitch fibres in the muscle of the animal.

A second factor contributing to the myoglobin content of a muscle is the age of the animal—muscles from older animals often have higher myoglobin concentrations. This accounts for the darker colour of beef relative to that of veal.

The size of an animal may also affect the myoglobin content of its muscles because of differences in basal metabolic rates (larger animals have a lower metabolism). Some smaller animals (such as rabbits) typically have a lower myoglobin concentration (0.02 percent of wet weight of muscle) and lighter coloured meat than larger animals such as horses (0.7 percent myoglobin) or deep-diving animals such as whales, which have very high concentrations of myoglobin (7 percent myoglobin) and dark, purple-coloured meat. Myoglobin concentration is also greater in intact males (animals that have not been castrated) of similar age, in muscles located closer to the bones, and in more physically active animals such as game.

Oxidation state of iron. The oxidation state of the iron atom of myoglobin also plays a significant role in meat colour. Meat such as beef viewed immediately after cutting is purple in colour because water is bound to the reduced iron atom of the myoglobin molecule (in this state the molecule is called deoxymyoglobin). Within 30 minutes after exposure to the air, beef slowly turns to a bright cherry-red colour in a process called blooming. Blooming is the result of oxygen binding to the iron atom (in this state the myoglobin molecule is called oxymyoglobin). After several days of exposure to air, the iron atom of myoglobin becomes oxidized and loses its ability to bind oxygen (the myoglobin molecule is now called metmyoglobin). In this oxidized condition, meat turns to a brown colour. Although the presence of this colour is not harmful, it is an indication that the meat is no longer fresh.

Tenderness. The tenderness of meat is influenced by a number of factors including the grain of the meat, the amount of connective tissue, and the amount of fat.

Meat grain. Meat grain is determined by the physical size of muscle bundles. Finer-grained meats are more tender and have smaller bundles, while coarser-grained meats are tougher and have larger bundles. Meat grain varies between muscles in the same animal and between the same muscle in different animals. As a muscle is used more frequently by an animal, the number of myofibrils in each muscle fibre increases, resulting in a thicker muscle bundle and a stronger (tougher) protein network. Therefore, the muscles from older animals and muscles of locomotion (muscles used for physical work) tend to produce coarser-grained meat.

Softening of collagen

Connective tissue. The amount of connective tissue in a muscle has a complex effect on the tenderness of the meat. The major component of connective tissue, collagen, has a tough, rigid structure. However, even though muscles from younger animals have more connective tissue, the meat derived from those muscles is generally more tender than that from older animals. This is due to the fact that collagen is broken down and denatured during the aging and cooking processes, forming a gelatin-like substance that makes the meat more tender. In addition, collagen becomes more rigid (resistant to breakdown and denaturation) with age, resulting in greater toughness of meat from older animals.

Fat. A high fat content within the adipose tissue and marbling sites of muscle contributes to the tenderness of the meat. During the cooking process the fat melts into a lubricant-type substance that spreads throughout the meat, increasing the tenderness of the final product.

LIVESTOCK SLAUGHTER PROCEDURES

The slaughter of livestock involves three distinct stages: preslaughter handling, stunning, and slaughtering. In the United States the humane treatment of animals during each of these stages is required by the Humane Slaughter Act. Figure 24 represents the general flow of the slaughter process.

Preslaughter handling. Preslaughter handling is a major concern to the livestock industry, especially the pork industry. Stress applied to livestock before slaughter can lead to undesirable effects on the meat produced from these animals. Preslaughter stress can be reduced by preventing the mixing of different groups of animals, by keeping livestock cool with adequate ventilation, and by avoiding overcrowding. Before slaughter, animals should be allowed access to water but held off feed for 12 to 24 hours to assure complete bleeding and ease of evisceration (the removal of internal organs).

Stunning. As the slaughter process begins, livestock are restrained in a chute that limits physical movement of the animal. Once restrained, the animal is stunned to ensure a humane end with no pain. Stunning also results in decreased stress of the animal and superior meat quality.

The three most common methods of stunning are mechanical, electrical, and carbon dioxide (CO_2) gas. The end result of each method is to render the animal unconscious. Mechanical stunning involves firing a bolt through the skull of the animal using a pneumatic device or pistol. Electrical stunning passes a current of electricity through the brain of the animal. CO_2 stunning exposes the animal to a mixture of CO_2 gas, which acts as an anesthetic.

Slaughtering. After stunning, animals are usually suspended by a hind limb and moved down a conveyor line for the slaughter procedures. They are typically bled (a process called sticking or exsanguination) by the insertion of a knife into the thoracic cavity and severance of the carotid artery and jugular vein. This method allows for maximal blood removal from the body. At this point in the process, the slaughtering procedures begin to differ by species.

Hogs. Hogs are usually stunned by electrical means or CO_2 gas. Mechanical stunning is not generally used in hogs because it may cause serious quality problems in the meat, including blood splashing (small, visible hemorrhages in the muscle tissue) in the lean meat.

Cleaning and dehairing

Hogs are one of the few domesticated livestock animals in which the skin is left on the carcass after the slaughter process. Therefore, after bleeding, the carcasses undergo an extensive cleaning procedure. First they are placed for about five minutes in a scalding tank of water that is between 57° and 63° C (135° and 145° F) in order to loosen hair and remove dirt and other material (called

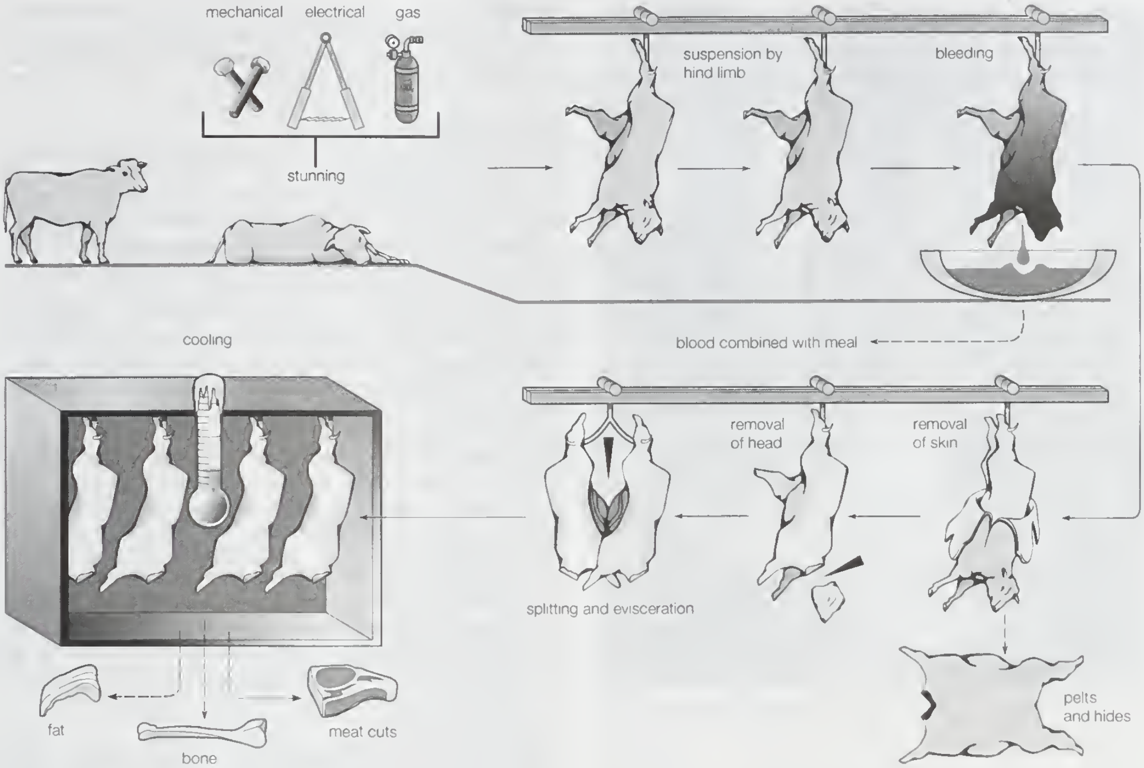

Figure 24: The basic slaughtering process.
Encyclopædia Britannica, Inc

scurf) from the skin. The careasses are then placed in a dehairing machine, whieh uses rubber paddles to remove the loosened hair. After dehairing, the careasses are suspended from a rail with hooks plaeed through the gambrel tendons on the hind limbs, and any residual hair is shaved and singed off the skin.

An exeeption to this proeedure oeeurs in certain specialized hog slaughter faeilities, sueh as "whole hog" sausage slaughter plants. In whole hog sausage production all the skeletal meat is trimmed off the earcass, and therefore the carcass is routinely skinned following exsanguination.

After eleaning and dehairing, heads are removed and earcasses are opened by a straight eut in the eentre of the belly to remove the viscera (the digestive system ineluding liver, stomaeh, bladder, and intestines and thc reproductive organs), pluek (thoraeie contents including heart and lungs), kidneys, and assoeiated fat (ealled leaf fat). The intestines are washed and eleaned to serve as natural casings for sausage produets. The earcasses are then split down the eentre of the baekbone into two "sides," whieh are placed in a cooler (called a "hot box") for approximately 24 hours before fabrieation into meat euts.

Cattle, calves, and sheep. These animals are usually stunned mechanically, but some sheep slaughter faeilities also use eleetrical stunning. The feet are removed from the careasses before they are suspended by the Achilles tendon of a hind leg for exsanguination. The carcasses are then skinned with the aid of mechanieal skinners ealled "hide pullers." Sheep pelts are often removed by hand in a process called "fisting." (In older operations, hides and pelts are removed by knife.) The hides (cattle and ealves) or pelts (sheep) are usually preserved by salting so that they can be tanned for leather produets. Heads are removed at the first eervical vertebra, ealled the atlas joint. Eviseeration and splitting are similar to hog proeedures, except that kidney, pelvie, and heart fat are typieally left in beef carcasses for grading. Careasses are then plaeed in a cooler for 24 hours (often 48 hours for beef) prior to fabrication into meat cuts.

By-products. By-products are the nonmeat materials colleeted during the slaughter proeess, commonly ealled offal. Variety meats include livers, brains, hearts, sweetbreads (thymus and pancreas), fries (testicles), kidneys, oxtails, tripe (stomaeh of eattle), and tongue. Bones and rendered meat are used as bone and meat mcal in animal feeds and fertilizers. Gelatin, obtained from high-eollagen produets sueh as pork snouts, pork skin, and dried rendered bone, is used in eonfeetions, jellies, and pharmaceuticals. Intestines are used as sausage easings. Hormones and other pharmaeeutieal produets sueh as insulin, heparin, and cortisone are obtained from various glands and tissues. Edible fats are used as lard (from hogs), tallow (from cattle), shortcnings, and cooking oils. Incdible fats are used in soap and candle manufaeturing and in various industrial grease formulations. Lanolin from sheep wool is used in cosmetics. Finally, hides and pelts are used in the manufaeture of leather.

MEAT INSPECTION

Meat inspeetion is mandatory and has the mission of assuring wholesomeness, safety, and aeeurate labeling of the meat supply. Although inspeetion procedures vary from eountry to country, they are eentred around the same basic prineiples and may be performed by government offieials, veterinarians, or plant personnel (see Figure 25). For example, in thc United States meat inspcction is administered through the Food Safety and Inspection Service of the United States Department of Agrieulture (USDA-FSIS) and is composed of several distinct programs. In general, these programs are representative of the basic inspeetion procedures used throughout the world and inelude antemortem inspeetion, postmortem inspeetion, reinspeetion during proeessing, sanitation, faeilities and equipment, labels and standards, eomplianee, pathology and epidemiology, residue monitoring and evaluation, federal-state relations, and foreign programs.

Inspeetion programs

Antemortem and postmortem inspeetion. Antemortem inspeetion identifies animals not fit for human eonsumption. Here animals that are down, disabled, diseased, or dead (known as 4D animals) are removed from the food ehain and labeled "eondemned." Other animals showing signs of being siek are labeled "suspeet" and are segregated from healthy animals for more thorough inspeetion during proeessing procedures.

Postmortem inspeetion of the head, viseera, and earcasses helps to identify whole carcasses, individual parts, or organs that are not wholesome or safe for human consumption.

Figure 25: Inspection of beef carcasses for grading by the U.S. Department of Agriculture.

© Jim Pickerell/Tony Stone Images

Reinspection during processing. Although previously inspected meat is used in the preparation of processed meat products, additional ingredients are added to processed meats. Reinspection during processing assures that only wholesome and safe ingredients are used in the manufacture of processed meat products (*e.g.*, sausage and ham).

Sanitation. Sanitation is maintained at all meat-packing and processing facilities by mandatory inspection both before and during the production process. This includes floors, walls, ceilings, personnel, clothing, coolers, drains, equipment, and other items that come in contact with food products. In addition, all water used in the production process must be potable (reasonably free of contamination).

Facilities and equipment. Facilities and equipment are inspected to ensure that they meet safety requirements. Facilities must have sufficient cooling and lighting, and rails from which carcasses are suspended must be high enough to assure that the carcasses never come in contact with the floor. Equipment must be able to be properly cleaned and must not adversely affect the wholesomeness of the products.

Labels and standards. Labels and standards regulations assure that products are accurately labeled, that nutritional information meets requirements, and that special label claims (*e.g.*, lean, light, natural) are accurate. Virtually all meat products must have the following components in their label: accurate product name, list of ingredients (in order of predominance), name and place of business of packer and manufacturer, net weight, inspection stamp and plant number, and handling instructions.

Compliance. Compliance assures that proper criminal, administrative, and civil sanctions are carried out against violators of food inspection laws. These violations include the sale of uninspected meat, the use of inaccurate labels, and the contamination of products.

Pathology and epidemiology. Pathology and epidemiology programs support the efforts of meat inspectors by working with other public health agencies to minimize the risk from widespread food-poisoning outbreaks. These agencies work to identify the causative agents of food poisoning and prevent repeated occurrences by improving prevention techniques (*e.g.*, proper handling and cooking and prevention of cross-contamination of raw and cooked products).

Residue monitoring and evaluation. Residue monitoring and evaluation programs identify animals containing harmful residues and remove them from the food chain. These residues include toxins from natural sources, from pesticides, from feeds, or from antibiotics administered to animals too soon before slaughter.

MEAT GRADING

Meat grading segregates meat into different classes based on expected eating quality (*e.g.*, appearance, tenderness, juiciness, and flavour) and expected yield of salable meat from a carcass. In contrast to meat-inspection procedures, meat-grading systems vary significantly throughout the world. These differences are due in large part to the fact that different countries have different meat quality standards. For example, in the United States cattle are raised primarily for the production of steaks and are fattened with high-quality grain feed in order to achieve a high amount of marbling throughout the muscles of the animal. High marbling levels are associated with meat cuts that are juicier, have more flavour, and are more tender. Therefore, greater marbling levels—and especially marbling that is finely textured and evenly distributed—improve the USDA quality grade (*i.e.*, Prime, Choice, or Select) of the beef. However, in Australia cattle are raised primarily for the production of ground beef products, and the highest quality grades are given to the leanest cuts of meat.

Some of the characteristics of meat used to assess quality and assign grades include: conformation of the carcass; thickness of external fat; colour, texture, and firmness of the lean meat; colour and shape of the bones; level of marbling; flank streaking; and degree of leanness.

RETAIL MEAT CUTTING

In the American style of meat cutting, whole carcasses are usually fabricated into more manageable primal (major) or subprimal (minor) cuts at the packing plant. This preliminary fabrication eases meat merchandising by reducing variability within the cuts. Primal and subprimal cuts are usually packaged and sold to retailers that further fabricate them into the products that are seen in the retail case.

Pork fabrication. Hogs are slaughtered at approximately 108 kilograms (240 pounds) and yield carcasses weighing approximately 76 kilograms (70 percent yield of live weight). Pork carcasses are usually divided into two sides before chilling, and each side is divided into four lean cuts plus other wholesale cuts. The four lean cuts are the ham, loin, Boston butt (Boston shoulder), and picnic shoulder. Figure 26 (top left) shows the major wholesale cuts of pork and the retail cuts derived from each.

Beef fabrication. Steers and heifers average 495 kilograms at slaughter and produce carcasses weighing 315 kilograms (63 percent yield of live weight). Beef carcasses are split into two sides on the slaughter floor. After chilling, each side is divided into quarters, the forequarter and hindquarter, between the 12th and 13th ribs. The major wholesale cuts fabricated from the forequarter are the chuck, brisket, foreshank, rib, and shortplate. The hindquarter produces the short loin, sirloin, rump, round, and flank. Figure 26 (top right) shows the major wholesale cuts of beef and the retail cuts derived from each.

Beef quarters

Lamb fabrication. Live sheep averaging 45 kilograms yield 22-kilogram carcasses (50 percent yield of live weight). Lamb carcasses are divided into two halves, the foresaddle and hindsaddle, on the fabrication floor. The foresaddle produces the major wholesale cuts of the neck, shoulder, rib, breast, and foreshank. The hindsaddle produces the major wholesale cuts of the loin, sirloin, leg, and hindshank. Figure 26 (bottom right) shows the major wholesale cuts of lamb and the retail cuts derived from each.

Veal fabrication. Veal is classified into several categories based on the ages of the animals at the time of slaughter. Baby veal (bob veal) is 2–3 days to 1 month of age and yields carcasses weighing 9 to 27 kilograms. Vealers are 4 to 12 weeks of age with carcasses weighing 36 to 68 kilograms. Calves are up to 20 weeks of age with carcasses ranging from 56 to 135 kilograms.

After slaughter, veal carcasses are split on the fabrication floor into two halves, the foresaddle and hindsaddle. The foresaddle produces the major wholesale cuts of the

MEAT COOKERY

The physical changes associated with cooking meat are caused by the effects of heat on connective tissue and muscle proteins.

Colour changes. In beef, changes in cooking temperatures ranging from 54° C or 130° F (very rare) to 82° C or 180° F (very well done) correspond to changes in colour from deep red or purple to pale gray. These colour changes are a result of the denaturation of the myoglobin in meat. Denaturation is the physical unfolding of proteins in response to such influences as extreme heat. The denaturation of myoglobin makes the protein unable to bind oxygen, causing the colour to change from the bright cherry red of oxymyoglobin to the brown of denatured myoglobin (equivalent to metmyoglobin).

Effects of heat on fibres and connective tissues

Structural changes. The colour changes during cooking correspond to structural changes taking place in the meat. These structural changes are due to the effects of heat on collagen (connective tissue protein) and actin and myosin (myofibrillar proteins). In the temperature range between 50° and 71° C (122° to 160° F) connective tissue in the meat begins to shrink. Further heating to temperatures above 71° C causes the complete denaturation of collagen into a gelatin-like consistency. Therefore, tough meats with relatively high amounts of connective tissues can be slowly cooked under moist conditions to internal temperatures above 71° C and made tender by gelatinization of the collagen within the meat, while at the same time maintaining juiciness.

The myofibrillar proteins also experience major changes during cooking. In the range of 40° to 50° C (104° to 122° F) actin and myosin begin to lose solubility as heat denaturation begins. At temperatures of 66° to 77° C (150° to 170° F) the myofibrillar proteins begin to shorten and toughen. Beyond 77° C (170° F) proteins begin to lose structural integrity (*i.e.,* they are completely denatured) and tenderness begins to improve.

The effects of heat on both connective tissue and myofibrillar proteins must be balanced in order to achieve maximum tenderness during cooking. Meats with low amounts of connective tissue are most tender when served closer to medium rare or rare so that muscle proteins are not hardened. Conversely, meats with heavy amounts of connective tissue require slow cooking closer to well done in order to achieve collagen gelatinization.

MEAT MICROBIOLOGY, SAFETY, AND STORAGE

When the conversion of muscle to meat begins, biological degradation of meat also commences. In the absence of a living immune system, microorganisms are unchecked in their ability to grow and reproduce on meat surfaces.

Food-borne microorganisms. Generally, food-borne microorganisms can be classified as either food-spoilage or food-poisoning, with each presenting unique characteristics and challenges to meat product safety and quality.

Food-spoilage microorganisms. These organisms are responsible for detrimental quality changes in meat. The changes include discoloration, unpleasant odours, and physical alterations. The principal spoilage organisms are molds and bacteria.

Molds usually appear dry and fuzzy and are white or green in colour. They can impart a musty flavour to meat. Common molds in meat include the genera *Cladosporium, Mucor,* and *Alternaria*. Slime molds produce a soft, creamy material on the surface of meat.

Common spoilage bacteria include *Pseudomonas, Acinetobacter,* and *Moraxella.* Under anaerobic conditions, such as in canned meats, spoilage can include souring, putrefaction, and gas production. This is a result of anaerobic decomposition of proteins by the bacteria.

Food-poisoning microorganisms. Food-poisoning microorganisms can cause health problems by either intoxication or infection. Intoxication occurs when food-poisoning microorganisms produce a toxin that triggers sickness when ingested. Several different kinds of toxins are produced by the various microorganisms. These toxins usually affect the cells lining the intestinal wall, causing vomiting and diarrhea. Microorganisms capable of causing food-poisoning intoxication include *Clostridium perfringens* (found in temperature-abused cooked meats—*i.e.,* meats that have not been stored, cooked, or reheated at the appropriate temperatures), *Staphylococcus aureus* (found in cured meats), and *Clostridium botulinum* (found in canned meats).

Toxins

Infection occurs when an organism is ingested by the host, then grows inside the host and causes acute sickness and, in extreme cases, death. Common infectious bacteria capable of causing food poisoning in undercooked or contaminated meats are *Salmonella, Escherichia coli, Campylobacter jejuni,* and *Listeria monocytogenes.*

Preservation and storage. Meat preservation helps to control spoilage by inhibiting the growth of microorganisms, slowing enzymatic activity, and preventing the oxidation of fatty acids that promote rancidity. There are many factors affecting the length of time meat products can be stored while maintaining product safety and quality. The physical state of meat plays a role in the number of microorganisms that can grow on meat. For example, grinding meat increases the surface area, releases moisture and nutrients from the muscle fibres, and distributes surface microorganisms throughout the meat. Chemical properties of meat, such as pH and moisture content, affect the ability of microorganisms to grow on meat. Natural protective tissues (fat or skin) can prevent microbial contamination, dehydration, or other detrimental changes. Covering meats with paper or protective plastic films prevents excessive moisture loss and microbial contamination.

Cold storage. Temperature is the most important factor influencing bacterial growth. Pathogenic bacteria do not grow well in temperatures under 3° C (38° F). Therefore, meat should be stored at temperatures that are as cold as possible. Refrigerated storage is the most common method of meat preservation. The typical refrigerated storage life for fresh meats is 5 to 7 days.

Freezer storage is an excellent method of meat preservation. It is important to wrap frozen meats closely in packaging that limits air contact with the meat in order to prevent moisture loss during storage. The length of time meats are held at frozen storage also determines product quality. Under typical freezer storage of −18° C (0° F) beef can be stored for 6 to 12 months, lamb for 6 to 9 months, pork for 6 months, and sausage products for 2 months.

Freezing. The rate of freezing is very important in maintaining meat quality. Rapid freezing is superior; if meats are frozen slowly, large ice crystals form in the meat and rupture cell membranes. When this meat is thawed, much of the original moisture found in the meat is lost as purge (juices that flow from the meat). For this reason cryogenic freezing (the use of supercold substances such as liquid nitrogen) or other rapid methods of freezing meats are used at the commercial level to maintain maximal product quality. It is important to note, however, that freezing does not kill most microorganisms; they simply become dormant. When the meat is thawed, the spoilage continues where it left off.

Rapid freezing

Thawing meats often can cause more detrimental quality changes than freezing. In contrast to freezing, thawing should be a slow process. Meats are best thawed in the refrigerator with packaging left intact, so that moisture loss is minimized. Placing frozen meats out on a warm countertop or under warm water subjects the meat's outer layers to room temperatures for long periods of time before the meat is ready for cooking (completely thawed). This rapid method provides a conducive environment for the growth of food-borne microorganisms and increases the risk of food poisoning.

Vacuum packaging. Oxygen is required for many bacteria to grow. For this reason most meats are vacuum-packaged, which extends the storage life under refrigerated conditions to approximately 100 days. In addition, vacuum packaging minimizes the oxidation of unsaturated fatty acids and slows the development of rancid meat.

Canning. The second most common method of meat preservation is canning. Canning involves sealing meat in a container and then heating it to destroy all microorganisms capable of food spoilage. Under normal conditions canned products can safely be stored at room temperature indefinitely. However, certain quality concerns can compel processors or vendors to recommend an optimal "sell by" date.

Drying. Drying is another common method of meat preservation. Drying removes moisture from meat products so that microorganisms cannot grow. Dry sausages, freeze-dried meats, and jerky products are all examples of dried meats capable of being stored at room temperature without rapid spoilage.

Fermentation. One ancient form of food preservation used in the meat industry is fermentation. Fermentation involves the addition of certain harmless bacteria to meat. These fermenting bacteria produce acid as they grow, lowering the pH of the meat and inhibiting the growth of many pathogenic microorganisms.

Irradiation. Irradiation, or radurization, is a pasteurization method accomplished by exposing meat to doses of radiation. Radurization is as effective as heat pasteurization in killing food-spoilage microorganisms. Irradiation of meat is accomplished by exposing meat to high-energy ionizing radiation produced either by electron accelerators or by exposure to gamma-radiation-emitting substances such as cobalt-60 or cesium-137. Irradiated products are virtually identical in character to nonirradiated products, but they have significantly lower microbial contamination. Irradiated fresh meat products still require refrigeration and packaging to prevent spoilage, but the refrigerated storage life of these products is greatly extended.

Curing and smoking. Meat curing and smoking are two of the oldest methods of meat preservation. They not only improve the safety and shelf life of meat products but also enhance the colour and flavour. Smoking of meat decreases the available moisture on the surface of meat products, preventing microbial growth and spoilage. Meat curing, as commonly performed in products such as ham or sausage, involves the addition of mixtures containing salt, nitrite, and other preservatives.

Salt decreases the moisture in meats available to spoilage microorganisms. Nitrite prevents microorganisms from growing and retards rancidity in meats. Nitrite also produces the pink colour associated with cured products by binding (as nitric oxide) to myoglobin. However, the use of nitrite in meat products is controversial owing to its potential cancer-causing activity.

Sodium erythorbate or ascorbate is another common curing additive. It not only decreases the risks associated with the use of nitrite but also improves cured meat colour development. Other common additives include alkaline phosphates, which improve the juiciness of meat products by increasing their water-holding ability. (H.R.C.)

Poultry

Poultry is a major source of consumable animal protein. For example, per capita consumption of poultry in the

Source: *Composition of Foods,* Agriculture Handbook no. 8–5, U.S. Department of Agriculture.

United States has more than quadrupled since the end of World War II as the industry has developed a highly efficient production system. Chickens and turkeys are the most common sources of poultry; however, other commercially available poultry meats come from ducks, geese, pigeons, quails, pheasants, ostriches, and emus.

CHARACTERISTICS OF POULTRY

Poultry is derived from the skeletal muscles of various birds and is a good source of protein, fat, and vitamins and minerals in the diet. (For a detailed discussion of muscles as food and their nutritional value, see above *Meat: Conversion of muscle to meat* and *Properties of meat.*) Table 8 shows the nutrient composition of several types of poultry.

Classification of birds. Birds bred for poultry production are generally grown for a particular amount of time or until they reach a specific weight. Rock Cornish hens, narrowly defined, are a hybrid cross specifically bred to produce small roasters; in the marketplace, however, the term is used to denote a small bird, five to six weeks old, that is often served whole and stuffed. Seven-week-old chickens are classified as broilers or fryers, and those that are 14 weeks old as roasters.

Fat content. The fat content of poultry differs in several ways from that found in red meat. Poultry has a higher proportion of unsaturated fatty acids compared with saturated fatty acids. Both turkey and chicken contain about 30 percent saturated, 43 percent monounsaturated, and 22 percent polyunsaturated fatty acids. The high levels of unsaturated fatty acids make poultry more susceptible to rancidity through the oxidation of the double bonds in the unsaturated fatty acids. Saturated fatty acids, on the other hand, do not contain double bonds in their hydrocarbon chains and are resistant to oxidation. However, this fatty acid ratio has led to the suggestion that poultry may be a more healthful alternative to red meat.

Location of fat deposits

In birds fat is primarily deposited under the skin or in the abdominal cavity. Therefore, a significant amount of the fat can be removed from poultry by removing the skin before eating.

Microbial contamination. Poultry provides an excellent medium for the growth of microorganisms. The principal spoilage bacteria found on poultry include *Pseudomonas, Staphylococcus, Micrococcus, Acinetobacter,* and *Moraxella.* In addition, poultry often supports the growth of certain pathogenic (disease-causing) bacteria, such as *Salmonella.*

Potential causes of contamination of poultry during the slaughtering and processing procedures include contact of the carcass with body parts that contain a high microbial load (*e.g.,* feathers, feet, intestinal contents), use of contaminated equipment, and physical manipulation of the meat (*e.g.,* deboning, grinding). Prevention of microbial contamination involves careful regulation and monitoring of the slaughtering and processing plants, proper handling and storage, and adequate cooking of raw and processed poultry products.

SLAUGHTERING PROCEDURES

Preslaughter handling. When the birds have reached "harvest" time, they are generally taken off of feed and water. This allows their digestive tracts to empty and reduces the potential for contamination during processing.

At night the birds are caught by specially trained crews and placed into plastic or wooden transport cages. The birds are then transported to the slaughterhouse, where the trucks are often kept between sets of fans to ventilate the cages.

In the next step the birds are removed from the cages and transferred to continuously moving shackles where they are suspended by both legs. The transfer is often done in a dark room illuminated by a red light; the birds are not sensitive to the red light and this helps to keep them calm.

The handling and transfer of birds both on the farm and at the slaughterhouse can be stressful. Stress can have negative effects on the quality of the final meat product, and therefore efforts are constantly being made to improve the preslaughter processes.

Slaughtering. *Stunning and killing.* After the birds have been transferred to the moving shackles, they are usually stunned by running their heads through a water bath that conducts an electric current. Stunning produces unconsciousness, but it does not kill the birds. The birds are killed either by hand or by a mechanical rotary knife that cuts the jugular veins and the carotid arteries at the neck. Any birds not killed by the machine are quickly killed by a person with a knife assigned to the bleed area. The birds are permitted to bleed for a fixed amount of time, depending on size and species (*e.g.,* 1½ minutes for broilers). Any bird that is not properly bled will be noticeably redder after feather removal and will be condemned.

Scalding. Following bleeding, the birds go through scalding tanks. These tanks contain hot water that softens the skin so that the feathers can be removed. The temperature of the water is carefully controlled. If retention of the yellow skin colour is desired, a soft-scald is used (about 50° C or 122° F). If a white bird is desired, a higher scald temperature is used, resulting in the removal of the yellow pellicle. Turkeys and spent hens (egg-laying birds that have finished their laying cycles) are generally run at higher temperatures—59° to 60° C (138° to 140° F).

Defeathering. The carcasses then go through the feather-picking machines, which are equipped with rubber "fingers" specifically designed to beat off the feathers. The carcasses are moved through a sequence of machines, each optimized for removing different sets of feathers. At this point the carcasses are usually singed by passing through a flame that burns off any remaining feathers.

Wax dipping

An extra process, called wax dipping, is often used for waterfowl, since their feathers are more difficult to remove. Following the mechanical feather picking, the carcasses are dipped in a melted, dark-coloured wax. The wax is allowed to harden and then is peeled away, pulling out the feathers at the same time. The wax is reheated and the feathers are filtered out so that the wax can be reused. This process is usually performed twice.

Figure 27: Packaging of poultry.

© Charles Gupton/Tony Stone Images

The blood and feathers accumulated during these early steps are generally collected and rendered to make blood meal and feather meal. The feathers from ducks and geese are often carefully collected and used for down production.

Removal of heads and legs. The heads of the birds go into a channel where they are pulled off mechanically; the legs of the birds are removed with a rotary knife (much like a meat slicer) either at the hock or slightly below it, depending on national custom. The carcasses drop off the shackle and are rehung by their hock onto the eviscerating shackle line. By law in the United States, the scalding and defeathering steps must be separated by a wall from the evisceration steps in order to minimize cross-contamination.

Evisceration and inspection. At this point the preen, or oil, gland is removed from the tail and the vent is opened so that the viscera (internal organs) can be removed. Evisceration can be done either by hand (with knives) or by using complex, fully automated mechanical devices. Automated evisceration lines can operate at a rate of about 70 birds per minute. The equipment is cleaned (with relatively high levels of chlorine) after each bird.

The carcasses are generally inspected during the evisceration process. The inspection procedures in the poultry industry vary around the world and may be performed by government inspectors, veterinarians, or plant personnel, depending on a country's laws. For example, in the United States the viscera are removed and placed on the side of the bird. Inspectors from the U.S. Department of Agriculture then examine the entire bird. The plant provides each inspector with an assistant who carries out any adjustments required by the inspector (*e.g.,* removing the entire bird or removing some part of the bird). The rejected parts are placed in a container marked "inedibles," and the contents are generally dyed (often a blue-purple), under supervision of the inspector, in order to prevent possible mixing with edible parts.

Following inspection, the carcasses are further cleaned. The viscera are separated from the carcasses, and the edible offal are removed from the inedible offal. The heart, stomach, and liver are all considered edible offal and are independently processed. Stomachs are generally cut open and the inside yellow lining of the stomach along with the stomach contents are removed.

The lungs and kidneys are removed separately from the other visceral organs using a vacuum pipe. A final inspection is often carried out at this point, and the carcasses are then washed thoroughly.

Chilling. After the carcasses have been washed, they are chilled to a temperature below 4° C (40° F). The two main methods for chilling poultry are water chilling and air chilling.

Water chilling. Water chilling is used throughout North America and involves a prechilling step in which a countercurrent flow of cold water is used to lower the temperature of the carcasses. The carcasses are then moved into a chiller—a large tank specifically designed to move the carcasses through in a specific amount of time. Two tanks are used to minimize cross-contamination.

Water chilling leads to an increase in poultry weight, and the amount of water gained is carefully regulated. In the United States the legal limits for water pickup are 8 percent for birds going directly to market and 12 percent for birds that will be further processed (the assumption is that they will lose the extra 4 percent by the time they reach the consumer).

Air chilling. Air chilling is the standard in Europe. The carcasses are hung by shackles and moved through coolers with rapidly moving air. The process is less energy-efficient than water chilling, and the birds lose weight because of dehydration. Air chilling prevents cross-contamination between birds. However, if a single bird contains a high number of pathogens, this pathogen count will remain on the bird. Thus, water chilling may actually result in a lower overall bacterial load, because many of the pathogens are discarded in the water.

The final temperature of the carcasses before shipment is usually about −2° to −1° C (28° to 30° F), just above the freezing point for poultry. In some cases a slight crusting on the surface occurs during the final chilling. For water-chilled carcasses this final chilling takes place after packaging, when the carcasses are placed in an air chiller.

PROCESSING OF POULTRY

Raw poultry products. Whole or individual parts of birds may be packaged raw for direct sale. Poultry packaged in the United States must include instructions about safe handling, including the need to wash all equipment that has come in contact with raw poultry and the need to wash one's hands before preparing other foods. Most raw turkey is sold frozen, while most chicken is sold fresh.

Fresh poultry. The birds are generally cut into a number of pieces, which are placed on plastic foam trays and covered with a plastic film (see Figure 27). A "diaper" (absorbent paper with a plastic backing) is often used to catch any liquid that may be released from the meat. Fresh poultry should be used within 14 to 21 days after slaughter and generally should not be kept in the home refrigerator for more than three days. In the United States, poultry that has been frozen to a temperature of −5° to −4° C (22° to 24° F) and then allowed to thaw can legally be sold as "fresh."

Storage of fresh poultry

Frozen poultry. Most frozen poultry is vacuum-packed in plastic bags and then frozen in high-velocity freezers. The birds are kept in cold storage until needed. Before freezing, poultry may be injected with various salts, flavourings, and oils in order to increase the juiciness of the meat. Injections are usually done with a multi-needle automatic injector, and information about the added ingredients is indicated on the package label.

Frozen storage time (including poultry bought fresh and frozen in a home freezer) depends on the temperature of the freezer, the quality of the packaging, and the cycling of the freezer. For best results poultry should be used within three months. Frozen poultry products can be used directly in the frozen state or thawed first. Thawing should be done in the refrigerator or under running cold water to minimize the potential for microbial contamination.

Processed poultry products. Poultry may be further processed into other products. The number of processed poultry products has increased dramatically since the 1970s because of the low cost of poultry and its versatile, bland flavour.

Battering and breading. Some poultry products are battered (*e.g.,* with beer batter) or battered and breaded (*e.g.,* with cracker meal, bread crumbs, or cornmeal) for frying. The meat may be either cooked or raw prior to coating. For battered and breaded poultry, the pieces are passed through a flour-based batter containing leavening and then through the breading ingredients. Many types of baked breadings have been developed to meet different tastes (*e.g.,* Cajun or Japanese). To hold the breading to the poultry, the product is deep-fried for a short time. If the poultry is fully cooked in this process, the consumer will only have to heat the product before eating it. Chicken nuggets are a battered and breaded product that is marinated before coating.

Tumbling and massaging. In the manufacturing of many poultry products, the meat is mixed with a variety of nonmeat ingredients, including flavourings, spices, and salt. Tumbling and massaging are gentle methods that produce a uniform meat mixture. A tumbler is a slowly rotating drum that works the meat into a smooth mixture. A massager is a large mixing chamber that contains a number of internal paddles. Cured turkey products (*i.e.,* treated with sodium nitrite), such as turkey ham and turkey pastrami, are often tumbled or massaged during processing.

Smoking. Poultry may be smoked. Prior to smoking, the birds must be brined (soaked in a salt solution containing certain flavourings) and then allowed to dry. Smoking can be done using real wood shavings or a smoke flavouring. In the last case this must be labeled in the United States as "natural smoke flavor added."

Minced poultry products

Deboning and grinding. Further processed poultry products leave the backs, necks, and bones available for their own processing. These materials are run through a machine called a mechanical deboner or a meat-bone separator. In general, the crushed meat and bones are continuously pressed against a screen and the edible, soft materials pushed through the screen. The resulting minced product is similar in texture to ground beef and has been used for many poultry products such as frankfurters (hot dogs) and bologna. Poultry frankfurters and bologna are made using a process similar to that for beef and pork. The meat is combined with water or ice, salt, and seasonings and chopped to emulsify the materials. The mixture is stuffed into plastic casings and cooked in a smokehouse. The meat is then quickly chilled, peeled, and vacuum-packaged. Bologna is stuffed into a larger casing and is not necessarily peeled. (J.M.Re.)

Eggs

While the primary role of the egg obviously is to reproduce the species, most eggs laid by domestic fowl, except those specifically set aside for hatching, are not fertilized but are sold mainly for human consumption. Eggs produced in quantity come from chickens, ducks, geese, turkeys, guinea fowl, pigeons, pheasants, and quail. This section describes the processing of chicken eggs, which represent the bulk of egg production in the United States and Europe. Duck eggs are consumed as food in parts of Europe and Asia, and goose eggs are also a food in many European countries. Commercial production of turkey and pigeon eggs is almost entirely confined to those used for producing turkey poults and young pigeons (squabs). Pheasant and quail eggs provide birds for hobby or sport use.

CHARACTERISTICS OF THE EGG

Structure and composition. The structural components of the egg are shown in Figure 28. They include the shell and shell membranes (10 percent); the albumen or white (60 percent), including the thick albumen, the outer thin albumen, the inner thin albumen, and the chalazae; and the yolk (30 percent). In a fertilized egg the yolk supplies the nutrients and the albumen supplies the water necessary for the development of the embryo. In addition, the layers of albumen act as a cushion to protect the embryo from jarring movements, while the chalazae help to maintain the orientation of the embryo within the egg.

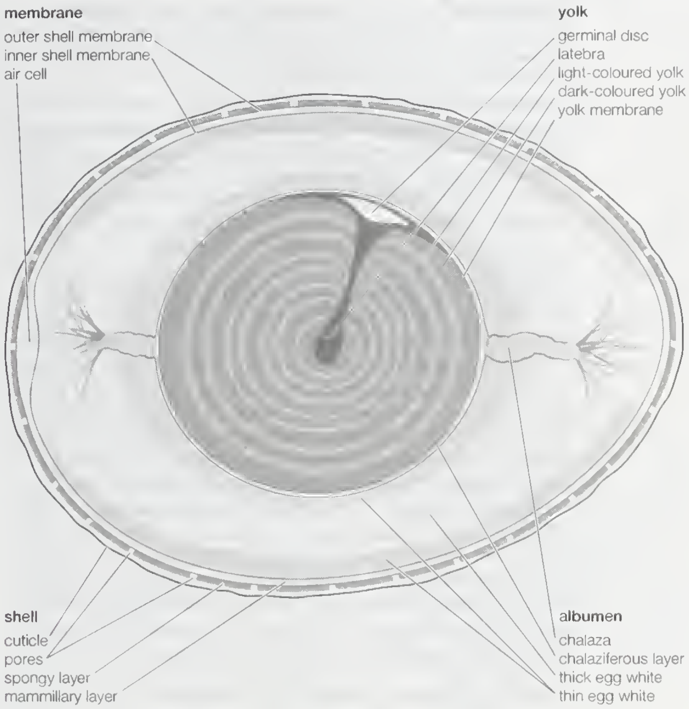

Figure 28: The structural components of an egg.
Encyclopædia Britannica, Inc.

The nutrient composition of chicken eggs is presented in Table 9. The whole egg is a source of high-quality protein (*i.e.,* proteins that contain all the amino acids needed in the human diet). In addition, it is an excellent source of all vitamins (except vitamin C) and contains many essential minerals, including phosphorus and zinc. All the fats, or lipids, as well as the cholesterol are found in the yolk. Yolk lipids are high in unsaturated fatty acids, with the ratio of unsaturated to saturated fatty acids commonly being 2 to 1. By influencing the diet of the hen, some processors are able to market shell eggs with yet a higher ratio of unsaturated to saturated fatty acids. Particular emphasis is being given to increasing the highly unsaturated long-chain omega-3 fatty acids by adding fish oil to the hen feed. Omega-3 fatty acids have been shown to play a role both in normal growth and development and in the prevention of many diseases.

The cholesterol content of a whole large egg is approximately 216 milligrams—a substantially lower figure than that reported before the late 1980s, when improved analytical techniques were instituted. Moreover, the egg industry has probably made some progress in lowering cholesterol content through genetic selection and improved diets.

Control of *Salmonella* contamination

Microbiology. More than 90 percent of all eggs are free of contamination at the time they are laid; contamination with *Salmonella* bacteria and with certain spoilage organisms occurs essentially afterward. Proper washing and sanitizing of eggs eliminates most *Salmonella* and spoilage organisms deposited on the shell. The organism *Salmonella enteritidis,* a common cause of gastroenteritis (a form of food poisoning), has been found to be trans-

Table 9: Nutrient Composition of Fresh Chicken Egg (per 100 grams)*

ferred through the hen ovary in fewer than 1 percent of all eggs produced. Ovarian-transferred *S. enteritidis* can be controlled by thorough cooking of eggs (*i.e.*, until there are no runny whites or yolk).

Certain spoilage organisms (*e.g.*, *Alcaligenes*, *Proteus*, *Pseudomonas*, and some molds) may produce green, pink, black, colourless, and other rots in eggs after long periods of storage. However, since eggs move through market channels rapidly, the modern consumer seldom encounters spoiled eggs.

FRESH EGGS

Fresh eggs are gathered on automatic collection belts at the farm and stored in a cooler at about 7° C (45° F). The eggs are then delivered to a central processing plant, where they are washed, sanitized, and graded. Grading involves the sorting of eggs into size and quality categories using automated machines. Flash candling (passing the eggs over a strong light source) detects any abnormalities such as cracked eggs and eggs containing bloodspots or other defects. Higher-grade eggs have a thick, upstanding white, an oval yolk, and a clean, smooth, unbroken shell.

In the United States eggs are sized on the basis of a minimum weight per dozen in ounces. One dozen extra large eggs weigh 27 ounces (765 grams); large eggs, 24 ounces; medium eggs, 21 ounces. Weight standards in other countries vary, but most are measured in metric units. For example, eggs might be sold in cartons of 10 eggs each.

Most eggs sold in modern supermarkets are approximately four to five days old. If kept refrigerated by the consumer, they will maintain good quality and flavour for about four weeks.

EGG PRODUCTS

Although per capita consumption of fresh eggs has declined since 1950, the utilization of eggs in other food products has increased. As ingredients, egg products are tailored to suit the specific needs of the food processor. For example, the foaming properties of the white or yolk are important in bakery products; egg yolk serves as an emulsifier in mayonnaise and salad oils; and the addition of eggs to meats or other foods enhances their binding properties.

Egg products, in the form of liquid, dried, or frozen eggs, are used as ingredients in many kinds of food products. In addition, specialty egg products are sold as convenience foods directly to the consumer or to food-service establishments.

Liquid egg products. Refrigerated liquid egg products have become increasingly popular, especially in food-service establishments. Liquid egg products may be delivered in a variety of packages, including bulk tank trucks, smaller portable tanks or "totes," paper cartons, hermetically sealed polyethylene bags, lacquer-coated tins, and plastic pails. These products include liquid egg whites, liquid egg yolks, and various blends of the whites and yolks. Normally, liquid egg products are pasteurized at 60° C (140° F) for 3.5 minutes and have a shelf life of two to six days. Some liquid egg products are processed using ultra-pasteurization and aseptic packaging techniques to extend their shelf life to about six weeks.

Shelf life of liquid egg products

Dried egg products. Dried or dehydrated eggs are less expensive to ship, more convenient to use, and easier to store than fresh whole eggs. Spray dryers are used to produce a high-quality egg product with foaming and emulsification properties similar to those of fresh eggs. The dehydrated eggs are packed in containers ranging from small pouches to large drums, depending on their commercial application. Several types of dried egg products are produced for various applications in the food industry (*e.g.*, cake mixes, salad dressings, pasta). These products include dried egg white solids, instant egg white solids, stabilized (glucose removed) whole egg solids, and various blends of whole egg and yolk with sugar or corn syrup. Most dried egg products have a storage life of one year when refrigerated.

Frozen egg products. Frozen egg products are often preferred as ingredients in certain food products..Salt, sugar, or corn syrup is normally added to yolks or whole eggs prior to freezing in order to prevent gelation or thickening of the products. Egg whites freeze well without any additives. Egg products are frozen at −23° C (−9° F) and are packed in different-sized pouches and waxed or plastic cartons. Products include egg whites, egg yolks, salted yolks, sugared yolks, salted whole eggs, sugared whole eggs, and various yolk and white blends with or without added sugar or salt. At frozen temperatures they have a shelf life of about one year.

Specialty egg products. A number of specialty egg products are available to both individual consumers and institutions. Commercial salad bars utilize cryogenically frozen and diced hard-cooked eggs and pickled or plain hard-cooked eggs. Several frozen, precooked egg products are available in markets, including egg pizza, scrambled eggs, omelettes, French toast, breakfast sandwiches, crepes, and quiches. Several low-cholesterol or cholesterol-free egg substitutes have been developed by replacing the egg yolk with vegetable oils, emulsifiers, stabilizers, colour, vitamins, and minerals. Fat-free egg substitutes have also been developed for commercial use. (G.W.F.)

Dairy products

Milk has been used by humans since the beginning of recorded time to provide both fresh and storable nutritious foods. In some countries almost half the milk produced is consumed as fresh pasteurized whole, low-fat, or skim milk. However, most milk is manufactured into more stable dairy products of worldwide commerce, such as butter, cheese, dried milks, ice cream, and condensed milk.

Cow milk (bovine species) is by far the principal type used throughout the world. Other animals utilized for their milk production include buffalo (in India, China, Egypt, and the Philippines), goats (in the Mediterranean countries), reindeer (in northern Europe), and sheep (in southern Europe). This section focuses on the processing of cow milk and milk products unless otherwise noted. In general, the processing technology described for cow milk can be successfully applied to milk obtained from other species.

In the early 1800s the average dairy cow produced less than 1,500 litres of milk annually. With advances in animal nutrition and selective breeding, one cow now produces an average of 6,500 litres of milk a year, with some cows producing up to 10,000 litres. The Holstein-Friesian cow produces the greatest volume, but other breeds such as Ayrshire, Brown Swiss, Guernsey, and Jersey, while producing less milk, are known for supplying milk that contains higher fat, protein, and total solids.

Milk production

PROPERTIES OF MILK

Nutrient composition. Although milk is a liquid and most often considered a drink, it contains between 12 and 13 percent total solids and perhaps should be regarded as a food. In contrast, many "solid" foods, such as tomatoes, carrots, and lettuce, contain as little as 6 percent solids.

Many factors influence the composition of milk, including breed, genetic constitution of the individual cow, age of the cow, stage of lactation, interval between milkings, and certain disease conditions. Since the last milk drawn at each milking is richest in fat, the completeness of milking also influences a sample. In general, the type of feed only slightly affects the composition of milk, but feed of poor quality or insufficient quantity causes both a low yield and a low percentage of total solids. Current feeding programs utilize computer technology to achieve the greatest efficiency from each animal.

The composition of milk varies among mammals, primarily to meet growth rates of the individual species. The proteins contained within the mother's milk are the major components contributing to the growth rate of the young animals. Human milk is relatively low in both proteins and minerals compared with that of cows and goats.

Goat milk has about the same nutrient composition as cow milk, but it differs in several characteristics. Goat milk is completely white in colour because all the beta-carotene (ingested from feed) is converted to vitamin A. The fat globules are smaller and therefore remain suspended, so the cream does not rise and mechanical homogenization is unnecessary. Goat milk curd forms into small, light flakes and is more easily digested, much like the curd formed from human milk. It is often prescribed for persons who are allergic to the proteins in cow milk and for some patients afflicted with stomach ulcers.

Sheep milk is rich in nutrients, having 18 percent total solids (5.8 percent protein and 6.5 percent fat). Reindeer milk has the highest level of nutrients, with 36.7 percent total solids (10.3 percent protein and 22 percent fat). These high-fat, high-protein milks are excellent ingredients for cheese and other manufactured dairy products.

The major components of milk are water, fat, protein, carbohydrate (lactose), and minerals (ash). However, there are numerous other highly important micronutrients such as vitamins, essential amino acids, and trace minerals. Indeed, more than 250 chemical compounds have been identified in milk. Table 10 shows the composition of fresh fluid milk and other dairy products.

Milk fat

Fat. The fat in milk is secreted by specialized cells in the mammary glands of mammals. It is released as tiny fat globules or droplets, which are stabilized by a phospholipid and protein coat derived from the plasma membrane of the secreting cell. Milk fat is composed mainly of triglycerides—three fatty acid chains attached to a single molecule of glycerol. It contains 65 percent saturated, 32 percent monounsaturated, and 3 percent polyunsaturated fatty acids. The fat droplets carry most of the cholesterol and vitamin A. Therefore, skim milk, which has more than 99.5 percent of the milk fat removed, is significantly lower in cholesterol than whole milk (2 milligrams per 100 grams of milk, compared with 14 milligrams for whole milk) and must be fortified with vitamin A.

Protein. Milk contains a number of different types of proteins, depending on what is required for sustaining the young of the particular species. These proteins increase the nutritional value of milk and other dairy products and provide certain characteristics utilized for many of the processing methods. A major milk protein is casein, which actually exists as a multisubunit protein complex dispersed throughout the fluid phase of milk. Under certain conditions the casein complexes are disrupted, causing curdling of the milk. Curdling results in the separation of milk proteins into two distinct phases, a solid phase (the curds) and a liquid phase (the whey).

Lactose. Lactose is the principal carbohydrate found in milk. It is a disaccharide composed of one molecule each of the monosaccharides (simple sugars) glucose and galactose. Lactose is an important food source for several types of fermenting bacteria. The bacteria convert the lactose into lactic acid, and this process is the basis for several types of dairy products.

In the diet lactose is broken down into its component glucose and galactose subunits by the enzyme lactase. The glucose and galactose can then be absorbed from the digestive tract for use by the body. Individuals deficient in lactase cannot metabolize lactose, a condition called lactose intolerance. The unmetabolized lactose cannot be absorbed from the digestive tract and therefore builds up, leading to intestinal distress.

Vitamins and minerals. Milk is a good source of many vitamins. However, its vitamin C (ascorbic acid) content is easily destroyed by heating during pasteurization. Vitamin D is formed naturally in milk fat by ultraviolet irradiation but not in sufficient quantities to meet human nutritional needs. Beverage milk is commonly fortified with the fat-soluble vitamins A and D. In the United States the fortification of skim milk and low-fat milk with vitamin A (in water-soluble emulsified preparations) is required by law.

Milk also provides many of the B vitamins. It is an excellent source of riboflavin (B_2) and provides lesser amounts of thiamine (B_1) and niacin. Other B vitamins found in trace amounts are pantothenic acid, folic acid, biotin, pyridoxine (B_6), and vitamin B_{12}.

Milk is also rich in minerals and is an excellent source of calcium and phosphorus. It also contains trace amounts of potassium, chloride, sodium, magnesium, sulfur, copper, iodine, and iron. A lack of adequate iron is said to keep milk from being a complete food.

Enzymes

Physical and biochemical properties. Milk contains many natural enzymes, and other enzymes are produced in milk as a result of bacterial growth. Enzymes are biological catalysts capable of producing chemical changes in organic substances. Enzyme action in milk systems is extremely important for its effect on the flavour and body of different milk products. Lipases (fat-splitting enzymes), oxidases, proteases (protein-splitting enzymes), and amylases (starch-splitting enzymes) are among the more important enzymes that occur naturally in milk. These classes of enzymes are also produced in milk by microbiological action. In addition, the proteolytic enzyme (*i.e.*, protease) rennin, produced in calves' stomachs to coagulate milk protein and aid in nutrient absorption, is used to coagulate milk for manufacturing cheese.

The coagulation of milk is an irreversible change of its protein from a soluble or dispersed state to an agglomerated or precipitated condition. Its appearance may be associated with spoilage, but coagulation is a necessary step in many processing procedures. Milk may be coagulated by rennin or other enzymes, usually in conjunction

with heat. Left unrefrigerated, milk may naturally sour or coagulate by the action of lactic acid, which is produced by lactose-fermenting bacteria. This principle is utilized in the manufacture of cottage cheese. When milk is pasteurized and continuously refrigerated for two or three weeks, it may eventually coagulate or spoil owing to the action of psychrophilic or proteolytic organisms that are normally present or result from postpasteurization contamination.

© Larry Lefever/Grant Heilman Photography, Inc

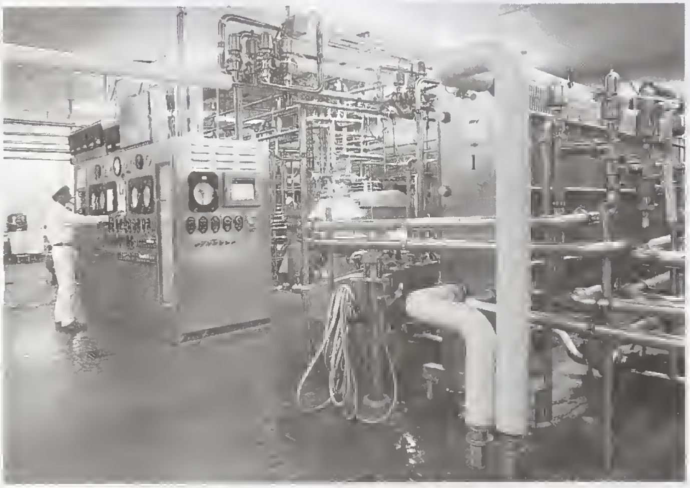

Figure 29: Equipment for the high-temperature short-time pasteurization of milk.

Milk fat is present in milk as an emulsion in a water phase. Finely dispersed fat globules in this emulsion are stabilized by a milk protein membrane, which permits the fat to clump and rise. The rising action is called creaming and is expected in all unhomogenized milk. In the United States, when paper cartons supplanted glass bottles, consumers stopped the practice of skimming cream from the top. Processors then introduced homogenization, a method of preventing gravity separation by forcing milk through very small openings under pressure, thus reducing fat globules to one-tenth their original size. Homogenization is practiced in many dairy processes in order to improve the physical properties of products (see below *Fresh fluid milk: Processing*).

Milk and other dairy products are very susceptible to developing off-flavours. Some flavours, given such names as "feed," "barny," or "unclean," are absorbed from the food ingested by the cow and from the odours in its surroundings. Others develop through microbial action due to growth of bacteria in large numbers. Chemical changes can also take place through enzyme action, contact with metals (such as copper), or exposure to sunlight or strong fluorescent light. Quality-control directors are constantly striving to avoid off-flavours in milk and other dairy foods.

FRESH FLUID MILK

Fresh fluid milk requires the highest-quality raw milk and is generally designated as Grade "A." This grade requires a higher level of sanitation and inspection on the farm than is necessary for "manufacturing grade" milk.

Quality concerns. Raw milk is a potentially dangerous food that must be processed and protected to assure its safety for humans. While most bovine diseases, such as brucellosis and tuberculosis, have been eliminated, many potential human pathogens inhabit the dairy farm environment. Therefore, it is essential that all milk be either pasteurized or (in the case of cheese) held for at least 60 days if made from raw milk. While milk from healthy cows is often totally bacteria-free, that condition quickly changes when milk is exposed to the farm environment.

Milk received at the processing plant is tested before being unloaded from either farm-based tank trucks or over-the-road tankers. The milk is checked for odour, appearance, proper temperature, acidity, bacteria, and the presence of drug residues. These tests take no longer than 10 to 15 minutes. If the tank load passes these tests, the milk is pumped into the plant's refrigerated storage tanks. The milk is then stored for the shortest possible time.

Processing. Essential steps in the processing of fluid milk into various dairy products are shown in Figure 30.

Pasteurization. Pasteurization is most important in all dairy processing. It is the biological safeguard which ensures that all potential pathogens are destroyed. Extensive studies have determined that heating milk to 63° C (145° F) for 30 minutes or 72° C (161° F) for 15 seconds kills the most resistant harmful bacteria. In actual practice these temperatures and times are exceeded, thereby not only ensuring safety but also extending shelf life.

High-temperature short-time pasteurization

Most milk today is pasteurized by the continuous high-temperature short-time (HTST) method (72° C or 161° F for 15 seconds or above). The HTST method is conducted in a series of stainless steel plates and tubes, with the hot pasteurized milk on one side of the plate being cooled by the incoming raw milk on the other side. (See Figure 29.) This "regeneration" can be more than 90 percent efficient and greatly reduces the cost of heating and cooling. There are many fail-safe controls on an approved pasteurizer system to ensure that all milk is completely heated for the full time and temperature requirement. If the monitoring instruments detect that something is wrong, an automatic flow diversion valve will prevent the milk from moving on to the next processing stage. Higher temperatures and sometimes longer holding times are required for the pasteurization of milk or cream with a high fat or sugar content.

Pasteurized milk is not sterile and is expected to contain small numbers of harmless bacteria. Therefore, the milk must be immediately cooled to below 4.4° C (40° F) and protected from any outside contamination. The shelf life for high-quality pasteurized milk is about 14 days when properly refrigerated.

Extended shelf life can be achieved through ultrapasteurization. In this case, milk is heated to 138° C (280° F) for two seconds and aseptically placed in sterile conventional milk containers. Ultrapasteurized milk and cream must be refrigerated and will last at least 45 days. This process does minimal damage to the flavour and extends the shelf life of slow-selling products such as cream, eggnog, and lactose-reduced milks.

Ultrahigh-temperature (UHT) pasteurization is the same heating process as ultrapasteurization (138° C or 280° F for two seconds), but the milk then goes into a more substantial container—either a sterile five-layer laminated "box" or a metal can. This milk can be stored without refrigeration and has a shelf life of six months to a year. Products handled in this manner do not taste as fresh, but they are useful as an emergency supply or when refrigeration is not available.

Centrifuge separators

Separation. Most modern plants use a separator to control the fat content of various products. A separator is a high-speed centrifuge that acts on the principle that cream or butterfat is lighter than other components in milk. (The specific gravity of skim milk is 1.0358, specific gravity of heavy cream 1.0083.) The heart of the separator is an airtight bowl with funnellike stainless steel disks. The bowl is spun at a high speed (about 6,000 revolutions per minute), producing centrifugal forces of 4,000 to 5,000 times the force of gravity. Centrifugation causes the skim, which is denser than cream, to collect at the outer wall of the bowl. The lighter part (cream) is forced to the centre and piped off for appropriate use.

An additional benefit of the separator is that it also acts as a clarifier. Particles even heavier than the skim, such as sediment, somatic cells, and some bacteria, are thrown to the outside and collected in pockets on the side of the separator. This material, known as "separator sludge," is discharged periodically and sometimes automatically when buildup is sensed.

Most separators are controlled by computers and can produce milk of almost any fat content. Current standards generally set whole milk at 3.25 percent fat, low-fat at 1 or 2 percent, and skim at less than 0.5 percent. (Most skim milk is actually less than 0.01 percent fat.)

Homogenization. Milk is homogenized to prevent fat globules from floating to the top and forming a cream layer or cream plug. Homogenizers are simply heavy-

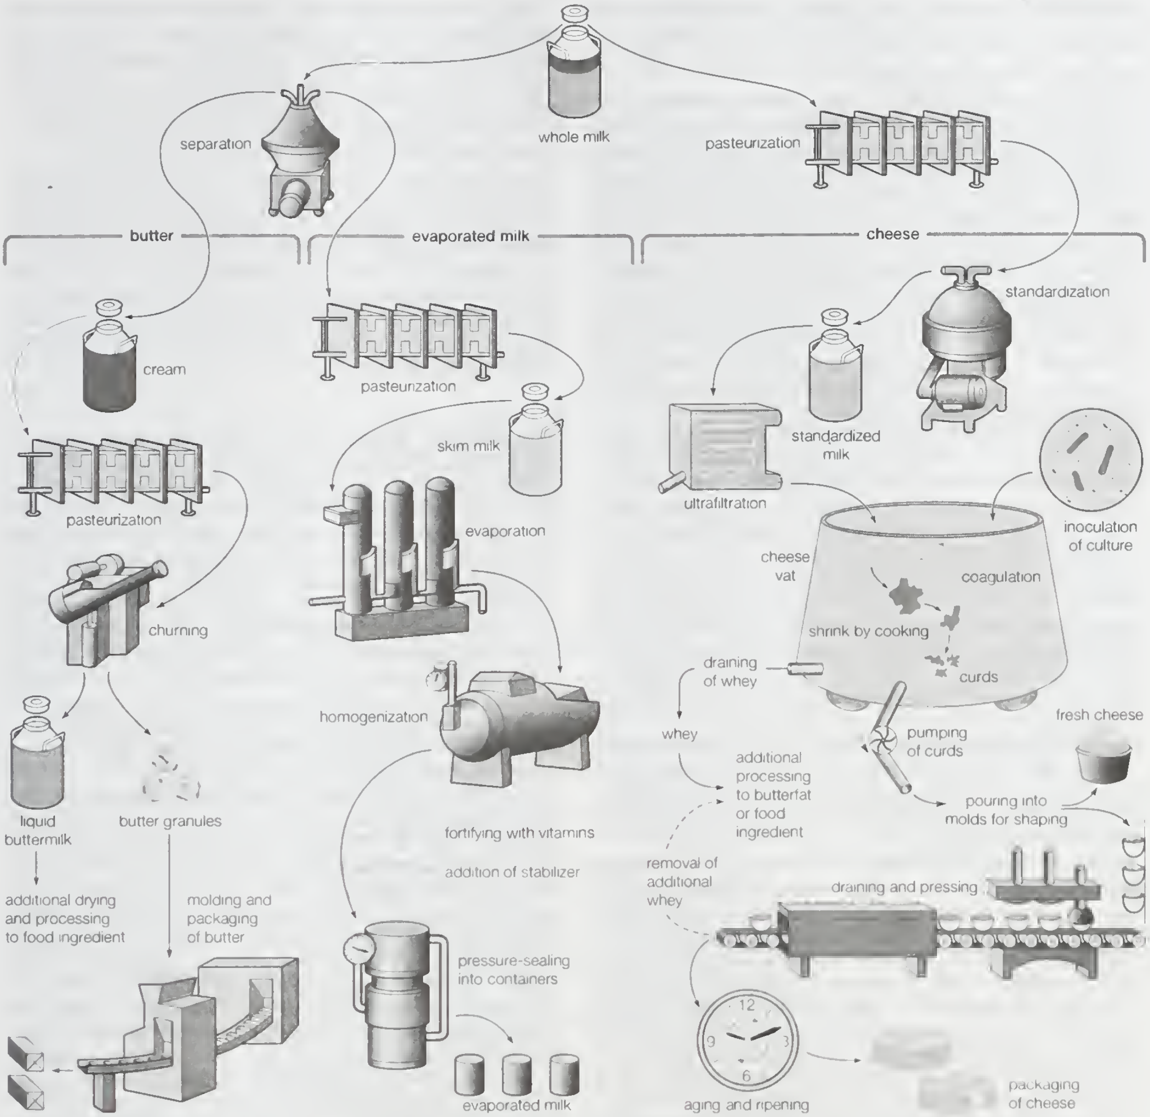

Figure 30: Essential steps in the processing of whole fresh milk into butter, evaporated milk, and cheese.
Encyclopædia Britannica, Inc.

duty, high-pressure pumps equipped with a special valve at the discharge end. They are designed to break up fat globules from their normal size of up to 18 micrometres to less than 2 micrometres in diameter (a micrometre is one-millionth of a metre). Hot milk (with the fat in liquid state) is pumped through the valve under high pressure, resulting in a uniform and stable distribution of fat throughout the milk.

Two-stage homogenization is sometimes practiced, during which the milk is forced through a second homogenizer valve or a breaker ring. The purpose is to break up fat clusters or clumps and thus produce a more uniform product with a slightly reduced viscosity.

Homogenization is considered successful when there is no visible separation of cream and the fat content in the top 100 millilitres of milk in a one-litre bottle does not differ by more than 10 percent from the bottom portion after standing 48 hours.

In addition to avoiding a cream layer, other benefits of homogenized milk include a whiter appearance, richer flavour, more uniform viscosity, better "whitening" in coffee, and softer curd tension (making the milk more digestible for humans). Homogenization is also essential for providing improved body and texture in ice cream, as well as numerous other products such as half-and-half, cream cheese, and evaporated milk.

Packaging. Until the mid 1880s milk was dipped from large cans into the consumer's own containers. The glass milk bottle was invented in 1884 and became the main container of retail distribution until World War II, when wax-coated paper containers were introduced. Plastic-coated paper followed and became the predominate container. Today more than 75 percent of retail sales are in translucent plastic jugs. Glass bottles make up less than 0.5 percent of the business and are used mostly at dairy stores and for home delivery.

Modern packaging machines are self-cleaning and provide an aseptic environment for milk packaging. Their improved design has allowed milk to remain fresh for at least 14 days and has made it possible for use with ultrapasteurizing equipment for extended shelf-life applications.

Specialty milks. Many specialty milks are now available (even in remote areas) as a result of the 45-day refrigerated shelf life of ultrapasteurized milk. One of the most useful products, lactose-reduced milk, is available in both nonfat and low-fat composition as well as in many flavoured versions. The lactose (milk sugar) is reduced by 70 to 100 percent, making it possible for lactose-intolerant individuals to enjoy the benefits of milk in their diets. Lactose reduction is accomplished by subjecting the appropriate milk to the action of the enzyme lactase in a refrigerated tank for approximately 24 hours. The enzyme breaks down the lactose to more readily digestible glucose and galactose. The reaction is halted when the lactose is consumed or when the milk is heat-treated. The resulting beverage is sweeter than regular milk but acceptable for most uses.

Lactose-reduced milk

Other specialty milks include calcium-fortified, special and seasonal flavours (*e.g.*, eggnog), and high-volume flavoured milk shakes (frequently served in schools).

CONDENSED AND DRIED MILK

Condensed and evaporated milk. Whole, low-fat, and skim milks, as well as whey and other dairy liquids, can be efficiently concentrated by the removal of water, using heat under vacuum. Since reducing atmospheric pressure lowers the temperature at which liquids boil, the water in milk is evaporated without imparting a cooked flavour. Water can also be removed by ultrafiltration and reverse osmosis, but this membrane technology is more expensive. Usually about 60 percent of the water is removed, which reduces storage space and shipping costs. Whole milk, when concentrated, usually contains 7.5 percent milk fat and 25.5 percent total milk solids. Skim milk can be condensed to approximately 20 to 40 percent solids, depending on the buyer's needs.

Condensed milk is often sold in refrigerated tank-truck loads to manufacturers of candy, bakery goods, ice cream, cheese, and other foods. When preserved by heat in individual cans, as shown in Figure 30, it is usually called "evaporated milk." In this process the concentrated milk is homogenized, fortified with vitamin D (A and D in evaporated skim milk), and sealed in a can sized for the consumer. A stabilizer, such as disodium phosphate or carrageenan, is also added to keep the product from separating during processing and storage. The sealed can is then sterilized at 118° C (244° F) for 15 minutes, cooled, and labeled. Evaporated milk keeps indefinitely, although staling and browning may occur after a year.

New ultrahigh-temperature (UHT) processing and aseptic filling of foil-lined cardboard or metal cans is also practiced. Although this process is more costly, the scorched flavour is not as pronounced as with conventionally processed evaporated milk.

Sweetened condensed milk

Sweetened condensed milk is also made by partially removing the water (as in evaporated milk) and adding sugar. The final product contains about 8.5 percent milk fat and at least 28 percent total milk solids. Sugar is added in sufficient amount to prevent bacterial action and subsequent spoilage. Usually, at least 60 percent sugar in the water phase is required to provide sufficient osmotic pressure for prevention of bacterial growth. Because sweetened condensed milk (or skim milk) is preserved by sugar, the milk merely needs to be pasteurized before being placed in a sanitary container (usually a metal can).

Dry milk products. Milk and by-products of milk production are often dried to reduce weight, to aid in shipping, to extend shelf life, and to provide a more useful form as an ingredient for other foods. In addition to skim and whole milk, a variety of useful dairy products are dried, including buttermilk, malted milk, instant breakfast, sweet cream, sour cream, butter powder, ice cream mix, cheese whey, coffee creamer, dehydrated cheese products, lactose, and caseinates. Many drying plants are built in conjunction with a butter-churning plant. These plants utilize the skim milk generated from the separated cream and the buttermilk produced from churning the butter. Most products are dried to less than 4 percent moisture to prevent bacterial growth and spoilage. However, products containing fat lose their freshness rather quickly owing to the oxidation of fatty acids, leading to rancidity.

Two types of dryers are used in the production of dried milk products—drum dryers and spray dryers. Each dryer has certain advantages.

Drum dryers. The simplest and least expensive is the drum, or roller, dryer. It consists of two large steel cylinders that turn toward each other and are heated from the inside by steam. The concentrated product is applied to the hot drum in a thin sheet that dries during less than one revolution and is scraped from the drum by a steel blade. The flakelike powder dissolves poorly in water but is often preferred in certain bakery products. Drum dryers are also used to manufacture animal feed where texture, flavour, and solubility are not a major consideration.

Spray dryers. Spray dryers are more commonly used since they do less heat damage and produce more soluble products. Concentrated liquid dairy product is sprayed in a finely atomized form into a stream of hot air. The air may be heated by steam-heated "radiators" or directly by sulfur-free natural gas. The drying chamber may be rectangular (the size of a living room), conical, or silo-shaped (up to five stories high). The powder passes from the drying chamber through a series of cyclone collectors and is usually placed in plastic-lined, heavy-duty paper bags.

Spray-dried milk is also difficult to reconstitute or mix with water. Therefore, a process called agglomeration was developed to "instantize" the powder, or make it more soluble. This process involves rewetting the fine, spray-dried powder with water to approximately 8 to 15 percent moisture and following up with a second drying cycle. The powder is now granular and dissolves very well in water. Virtually all retail packages of nonfat dry milk powder are instantized in this manner.

BUTTER

Composition. Butter is one of the most highly concentrated forms of fluid milk. Twenty litres of whole milk are needed to produce one kilogram of butter. This process leaves approximately 18 litres of skim milk and buttermilk, which at one time were disposed of as animal feed or waste. Today the skim portion has greatly increased in value and is fully utilized in other products.

Commercial butter is 80–82 percent milk fat, 16–17 percent water, and 1–2 percent milk solids other than fat (sometimes referred to as curd). It may contain salt, added directly to the butter in concentrations of 1 to 2 percent. Unsalted butter is often referred to as "sweet" butter. This should not be confused with "sweet cream" butter, which may or may not be salted. Reduced-fat, or "light," butter usually contains about 40 percent milk fat.

"Sweet" butter and "sweet cream" butter

Before World War II much of the butter produced in the United States was made from gathered cream. Farmers separated milk on the farm and shipped cans of cream to a butter factory, sometimes once or twice a week. The cream was often sour and needed to be neutralized (with sodium hydroxide) before churning. When transportation and the value of the skim portion improved, whole milk was shipped to the creamery, providing a supply of "sweet cream" (*i.e.*, cream that had not soured) for butter making. With these improvements came the advent of higher-quality butter and the demise of naturally soured buttermilk. Virtually all butter in the United States today is sweet cream butter. A notable exception is butter made from whey cream salvaged in the cheese-making process. The quality of fresh whey cream butter is indistinguishable from sweet cream butter.

Production. As shown in Figure 30, butter is produced when the cream emulsion in unhomogenized milk is destabilized by agitation, or churning. Breaking the emulsion produces butterfat granules the size of rice grains. The granules mat together and separate from the water phase or serum, which is known as buttermilk. (This milky liquid is drained away and is either concentrated or dried, later to become an ingredient in ice cream, candy, or other foods.) The butterfat is then washed with clean water and "worked" (kneaded) until more buttermilk separates and is removed. Ultimately, only about 16 percent of the water and milk solids present in the original milk remains trapped in the butter.

The churning process can take 40 to 60 minutes to complete in a traditional churn, but butter is more commonly made by high-speed continuous "churns" in factories. Although the basic principle is the same, in the continuous churn cream is pumped into a cylinder and mixed by high-speed blades, forming butter granules in seconds. The butter granules are forced through perforated plates while the buttermilk is drained from the system. A salt solution may be added if salted butter is desired. The butter is then worked in a twin screw extruder and emerges ready to be packaged.

Quality concerns. The quality of butter is based on its body, texture, flavour, and appearance. In the United States the Department of Agriculture (USDA) assigns quality grades to butter based on its score on a standard quality point scale. Grade AA is the highest possible grade; Grade AA butter must achieve a numerical score of 93

Grades of butter

out of 100 points based on its aroma, flavour, and texture. Salt (if present) must be completely dissolved and thoroughly distributed. Grade A butter is almost as good, with a score of 92 out of 100 points. Grade B butter is based on a score of 90 points, and it usually is used only for cooking or manufacturing. The flavour of Grade B is not as fresh and sweet, and its body may be crumbly, watery, or sticky.

Additions and treatment. The addition of salt to butter contributes to its flavour and also acts as a preservative. Added in concentrations of approximately 2 percent, all the salt goes into solution in the water phase. Since the water content of butter is less than 16 percent of the total volume, each water droplet can contain more than 10 percent salt. Such a concentration in the water phase limits bacterial growth overall, since the fat portion of butter is generally safe from microbial degradation.

Butter may contain added colouring. Butter from cows that are eating dry, stored feed during the winter may not contain enough beta-carotene for proper colouring, as it does when cows are pasture-fed. In such cases small amounts of a yellow vegetable colouring from the seed of the annatto tree may be added to enhance the colour.

Because butter is so firm when first removed from the refrigerator, it is sometimes whipped to improve spreadability. Generally, volume is increased by 50 percent by whipping in air—or, better still, nitrogen or an inert gas in order to prevent oxidation of the fat. Whipped butter, both salted and sweet, is sold in small plastic-coated tubs.

ICE CREAM AND OTHER FROZEN DESSERTS

Ice cream evolved from flavoured ices that were popular with the Roman nobility in the 4th century BC. The emperor Nero is known to have imported snow from the mountains and topped it with fruit juices and honey. In the 13th century Marco Polo was reported to have returned from China with recipes for making water and milk ices.

The discovery that salt would lower the freezing point of cracked ice led to the first practical method of making ice cream. Making ice cream in the home was greatly simplified by the invention of the wooden bucket freezer with rotary paddles. In 1851 the first wholesale ice cream was manufactured in Baltimore. With the development of mechanical refrigeration, widespread distribution of ice cream became possible. Ice cream parlours and drugstore soda counters flourished. With refrigerator-freezers now a standard domestic appliance, more than half of all frozen desserts are consumed at home.

Composition of frozen desserts. Standards for ice cream and most frozen desserts are closely regulated. In the United States, for example, ice cream must contain at least 10 percent fat and 20 percent total milk solids. In freezing, the volume may be doubled by the inclusion of air (known as overrun), but the increase in volume is limited to 100 percent by the requirement that the finished product weigh at least 4.5 pounds per gallon. Total food solids must weigh 1.6 pounds per gallon, thus limiting the water content. Regulations also require all ingredients to be listed, with some additives (such as stabilizers) limited to very small amounts.

The principal frozen desserts are ice cream, frozen custard, ice milk, frozen yogurt, sherbet, and water ices. Ice cream has the highest fat content, ranging from 10 to 20 percent. Frozen custard, or French ice cream, is basically the same formula as ice cream but contains added eggs or egg solids (usually 1.4 percent by weight). Ice milk may be more commonly called "light" or "reduced-fat" ice cream. It contains between 2 and 7 percent fat and at least 11 percent total milk solids. Frozen yogurt is a cultured frozen product containing the same ingredients as ice cream. It must contain at least 3.25 percent milk fat and 8.25 percent milk solids other than fat and must weigh at least five pounds per gallon. Low-fat frozen yogurt contains between 0.5 and 2 percent milk fat. Nonfat frozen yogurt is limited to less than 0.5 percent milk fat. Frozen yogurts should always contain live cultures of bacteria (see below *Cultured dairy foods: Yogurt*). The target overrun for ice cream, ice milk, and frozen yogurt is 65 to 100 percent. Premium ice creams may be as low as 20 percent overrun, while soft ice creams are in the 30 to 50 percent range.

Frozen yogurt

Sherbets contain relatively small quantities of milk products. Most standards require between 1 and 2 percent milk fat and between 2 and 5 percent total milk solids. Sherbet contains considerably more sugar and less air than ice cream (the target overrun is 30 to 40 percent), and therefore it is heavier and often contains more calories per serving. Water ices are similar to sherbet, but they contain no milk solids and have a target overrun of 20 to 30 percent.

Imitation ice cream, known as mellorine, is made in some parts of the United States and other countries. It is made with less expensive vegetable oils instead of butterfat but utilizes dairy ingredients for the milk protein part. Mellorines are intended to compete with ice cream in places where butterfat prices are high.

Ice cream manufacture. The essential ingredients in ice cream are milk, cream, sugar, flavouring, and stabilizer. Cheaper ingredients such as dry whey, corn syrup, and artificial flavourings may be substituted to create a lower-cost product.

The first step in ice cream making is formulating a suitable mix. The mix is composed of a combination of dairy ingredients, such as fresh milk and cream, frozen cream, condensed or dried skim, buttermilk, dairy whey, or whey protein concentrate. Sugars may include sucrose, corn syrup, honey, and other syrups. Stabilizers and emulsifiers are added in small amounts to help prevent formation of ice crystals, particularly during temperature fluctuations in storage.

The ice cream mix is pasteurized at no less than 79° C (175° F) for 25 seconds. The heated mix is typically homogenized in order to assure a smoother body and texture. Homogenizing also prevents churning (*i.e.*, separating out of fat granules) of the mix in the freezer and increases the viscosity. (Since smaller fat globules have more surface area, the associated milk protein can hydrate more water and produce a more viscous fluid.)

After homogenization, the hot mix is quickly cooled to 4.4° C (40° F). The mix must age at this temperature for at least four hours to allow the fat to solidify and fat globules to clump. This aging process results in quicker freezing and a smoother product.

Freezing

The next step, freezing the mix, is accomplished by one of two methods: continuous freezing, which uses a steady flow of mix, or batch freezing, which makes a single quantity at a time. For both methods, the objective is to freeze the product partially and, at the same time, incorporate air. The freezing process is carried out in a cylindrical barrel that is cooled by a refrigerant, either ammonia or Freon (trademark). The barrel is equipped with stainless steel blades, called dasher blades, which scrape the frozen mixture from the sides of the freezing cylinder and incorporate or whip air into the product. The amount of air incorporated during freezing is controlled by a pump or the dasher speed. Depending on individual conditions, freezing can be instantaneous in the continuous freezer or require approximately 10 minutes in the batch freezer.

Semifrozen ice cream leaves the freezer at a temperature between −9° and −5° C (16° and 23° F). It is placed in a suitable container and conveyed to a blast freezer, where temperatures are in the range of −29° to −34° C (−20° to −30° F). While in this room, the ice cream continues to freeze without agitation. Rapid freezing at this stage prevents the formation of large ice crystals and favours a smooth body and texture. The length of time in the hardening room depends on the size of the package, but usually 6 to 12 hours are required to bring the internal ice cream temperature to −18° C (0° F) or below. In larger manufacturing plants, final freezing takes place in a hardening tunnel, where packages are automatically conveyed on a continuous belt to the final storage area.

Much of the appeal of ice cream comes from the variety of standard and holiday flavours available throughout the year. Most ice cream manufacturers make a standard mix consisting of milk, cream, sugars, and stabilizers, to which flavours may be added just prior to freezing. High-volume flavours such as vanilla, chocolate, and strawberry may be blended in their own large batch tanks. For flavours with large particles, such as fruit, nuts, cookies, or candy parts, a "feeder" on the outlet of the freezer is used to inject the material. Ingredients such as fruits and nuts are carefully selected and specially treated to avoid introducing unwanted bacteria into the already pasteurized mix.

Ice cream and other frozen desserts require no preservatives and have long shelf lives if they are kept below −23° C (−10° F) and are protected from temperature fluctuations. Airtight packaging materials have made it possible to consider frozen storage of six months or longer without loss of flavour or body and texture. When ice cream is finally dipped, composition and overrun will determine ideal scooping temperature. This can vary from −16° to −9° C (3° to 15° F), with lower temperatures resulting in less dipping loss but more effort on the part of the server.

Ice cream can also be freeze-dried by the removal of 99 percent of the water. Freeze-drying eliminates the need for refrigeration and provides a high-energy food for hikers and campers and a "filling" centre for candy and other confections.

CULTURED DAIRY FOODS

With the development of microbiological and nutritional sciences in the late 19th century came the technology necessary to produce cultured dairy products on an industrial or commercial basis. Fermented milks had been made since early times, when warm raw milk from cows, sheep, goats, camels, or horses was naturally preserved by common strains of *Streptococcus* and *Lactobacillus* bacteria. (The "cultures" were obtained by including a small portion from the previous batch.) These harmless lactic acid producers were effective in suppressing spoilage and pathogenic organisms, making it possible to preserve fresh milk for several days or weeks without refrigeration. Cultured products eventually became ethnic favourites and were introduced around the world as people migrated.

Conversion of lactose by bacteria

Central to the production of cultured milk is the initial fermentation process, which involves the partial conversion of lactose (milk sugar) to lactic acid. Lactose conversion is accomplished by lactic-acid–producing *Streptococcus* and *Lactobacillus* bacteria. At temperatures of approximately 32° C (90° F), these bacteria reproduce very rapidly, perhaps doubling their population every 20 minutes. Many minute by-products that result from their metabolic processes assist in further ripening and flavouring of the cultured product. Subsequent or secondary fermentations can result in the production of other compounds, such as diacetyl (a flavour compound found in buttermilk) and alcohol (from yeasts in kefir), as well as butyric acid (which causes bitter or rancid flavours).

Cultured buttermilk, sour cream, and yogurt are among the most common fermented dairy products in the Western world. Other, lesser-known products include kefir, koumiss, acidophilus milk, and new yogurts containing *Bifidobacteria*. Cultured dairy foods provide numerous potential health benefits to the human diet. These foods are excellent sources of calcium and protein. In addition, they may help to establish and maintain beneficial intestinal bacterial flora and reduce lactose intolerance.

Buttermilk. Because of its name, most people assume buttermilk is high in fat. Actually, the name refers to the fact that buttermilk was once the watery end-product of butter making (shown in Figure 30). Modern buttermilk is made from low-fat or skim milk and has less than 2 percent fat and sometimes none. Its correct name in many jurisdictions is "cultured low-fat milk" or "cultured nonfat milk."

The starting ingredient for buttermilk is skim or low-fat milk. The milk is pasteurized at 82° to 88° C (180° to 190° F) for 30 minutes, or at 90° C (195° F) for two to three minutes. This heating process is done to destroy all naturally occurring bacteria and to denature the protein in order to minimize wheying off (separation of liquid from solids).

The milk is then cooled to 22° C (72° F), and starter cultures of desirable bacteria, such as *Streptococcus lactis, S. cremoris, Leuconostoc citrovorum,* and *L. dextranicum,* are added to develop buttermilk's acidity and unique flavour. These organisms may be used singly or in combination to obtain the desired flavour.

The ripening process takes about 12 to 14 hours (overnight). At the correct stage of acid and flavour, the product is gently stirred to break the curd, and it is cooled to 7.2° C (45° F) in order to halt fermentation. It is then packaged and refrigerated.

Sour cream. Sour cream is made according to the same temperature and culture methods as used for buttermilk. The main difference is the starting material—sour cream starts with light 18 percent cream.

Yogurt. Yogurt is made in a similar fashion to buttermilk and sour cream, but it requires different bacteria and temperatures. Whole, low-fat, or skim milk is fortified with nonfat dry milk or fresh condensed skim milk, in order to raise the total solids to 14 to 16 percent. The mixture is heat-treated as for buttermilk and then cooled to 45.6° to 46.7° C (114° to 116° F). At this point a culture of equal parts *Lactobacillus bulgaricus* and *Streptococcus thermophilus* is added to the warm milk, followed by one of two processing methods. For set, or sundae-style, yogurt (fruit on the bottom), the cultured mixture is poured into cups containing the fruit, held in a warm room until the milk coagulates (usually about four hours), and then moved to a refrigerated room. For blended (Swiss- or French-style) yogurt, the milk is allowed to incubate in large heated tanks. After coagulation occurs, the mixture is cooled, fruit or other flavours are added, and the product is placed in containers and immediately made ready for sale.

Set yogurt and blended yogurt

Many yogurt manufacturers have added *Lactobacillus acidophilus* to their bacterial cultures. *L. acidophilus* has possible health benefits in easing yeast infections and restoring normal bacterial balance to the intestinal tract of humans after antibiotic treatment.

CHEESE

Primitive forms of cheese have been made since humans started domesticating animals. No one knows exactly who made the first cheese, but, according to one ancient legend, it was made accidentally by an Arabian merchant crossing the desert. The merchant put his drinking milk in a bag made from a sheep's stomach. The natural rennin in the lining of the pouch, along with the heat from the sun, caused the milk to coagulate and then separate into curds and whey. At nightfall, the whey satisfied the man's thirst, and the curd (cheese) had a delightful flavour and satisfied his hunger.

From its birthplace in the Middle East, cheese making spread as far as England with the expansion of the Roman Empire. During the Middle Ages, monks and merchants of Europe made cheese an established food of that area. In 1620, cheese and cows were part of the ship's stores carried to North America by the Pilgrims on the *Mayflower*. Until the middle of the 19th century, cheese was a local farm product. Few, if any, distinct varieties of cheese were developed deliberately. Rather, cheese makers in each locality made a cheese that, when ripened under specific conditions of air temperature and humidity, mold, and milk source, acquired certain characteristics of its own. Different varieties appeared largely as a result of accidental changes or modifications in one or more steps of the cheese-making process. Because there was little understanding of the bacteriology and chemistry involved, these changes were little understood and difficult to duplicate. Cheese making was an art, and the process was a closely guarded secret that was passed down from one generation to the next.

With increasing scientific knowledge came a greater understanding of the bacteriological and chemical changes that are necessary to produce many types of cheese. Thus, it has become possible to control more precisely each step in the cheese-making process and to manufacture a more uniform product. Cheese making is now a science as well as an art.

Fundamentals of cheese making. The cheese-making process consists of removing a major part of the water contained in fresh fluid milk while retaining most of the solids. Since storage life increases as water content decreases, cheese making can also be considered a form of food preservation through the process of milk fermentation. The fermentation of milk into finished cheese requires several essential steps: preparing and inoculating the milk with lactic-acid–producing bacteria, curdling the milk, cutting the curd, shrinking the curd (by cooking), draining or dipping the whey, salting, pressing, and ripening. These steps, which are illustrated in Figure 30, begin with four basic ingredients: milk, microorganisms, rennet, and salt.

Inoculation and curdling. Milk for cheese making must be of the highest quality. Because the natural microflora present in milk frequently include undesirable types called psychrophiles, good farm sanitation and pasteurization or partial heat treatment are important to the cheese-making process. In addition, the milk must be free of substances that may inhibit the growth of acid-forming bacteria (*e.g.,* antibiotics and sanitizing agents). Milk is often pasteurized to destroy pathogenic microorganisms and to eliminate spoilage and defects induced by bacteria. However, since pasteurization destroys the natural enzymes found in milk, cheese produced from pasteurized milk ripens less rapidly and less extensively than most cheese made from raw or lightly heat-treated milk.

During pasteurization, the milk may be passed through a standardizing separator to adjust the fat-to-protein ratio of the milk. In some cases the cheese yield is improved by concentrating protein in a process known as ultrafiltration. The milk is then inoculated with fermenting microorganisms and rennet, which promote curdling.

Rennet

The fermenting microorganisms carry out the anaerobic conversion of lactose to lactic acid. The type of organisms used depends on the variety of cheese and on the production process. Rennet is an enzymatic preparation that is usually obtained from the fourth stomach of calves. It contains a number of proteolytic (protein-degrading) enzymes, including rennin and pepsin. Some cheeses, such as cottage cheese and cream cheese, are produced by acid coagulation alone. In the presence of lactic acid, rennet, or both, the milk protein casein clumps together and precipitates out of solution; this is the process known as curdling, or coagulation. Coagulated casein assumes a solid or gellike structure (the curd), which traps most of the fat, bacteria, calcium, phosphate, and other particulates. The remaining liquid (the whey) contains water, proteins resistant to acidic and enzymatic denaturation (*e.g.,* antibodies), carbohydrates (lactose), and minerals.

Lactic acid produced by the starter culture organisms has several functions. It promotes curd formation by rennet (the activity of rennet requires an acidic pH), causes the curd to shrink, enhances whey drainage (syneresis), and helps prevent the growth of undesirable microorganisms during cheese making and ripening. In addition, acid affects the elasticity of the finished curd and promotes fusion of the curd into a solid mass. Enzymes released by the bacterial cells also influence flavour development during ripening.

Salt is usually added to the curd. In addition to enhancing flavour, it helps to withdraw the whey from the curd and inhibits the growth of undesirable microorganisms.

Cutting and shrinking. After the curd is formed, it is cut with fine wire "knives" into small cubes approximately one centimetre (one-half inch) square. The curd is then gently heated, causing it to shrink. The degree of shrinkage determines the moisture content and the final consistency of the cheese. Whey is removed by draining or dipping. The whey may be further processed to make whey cheeses (*e.g.,* ricotta) or beverages, or it may be dried in order to preserve it as a food ingredient.

Ripening. Most cheese is ripened for varying amounts of time in order to bring about the chemical changes necessary for transforming fresh curd into a distinctive aged cheese. These changes are catalyzed by enzymes from three main sources: rennet or other enzyme preparations of animal or vegetable origin added during coagulation, microorganisms that grow within the cheese or on its surface, and the cheese milk itself. The ripening time may be as short as one month, as for Brie, or a year or more, as in the case of sharp cheddar.

The ripening of cheese is influenced by the interaction of bacteria, enzymes, and physical conditions in the curing room. The speed of the reactions is determined by temperature and humidity conditions in the room as well as by the moisture content of the cheese. In most cheeses lactose continues to be fermented to lactic acid and lactates, or it is hydrolyzed to form other sugars. As a result, aged cheeses such as Emmentaler and cheddar have no residual lactose.

In a similar manner, proteins and lipids (fats) are broken down during ripening. The degree of protein decomposition, or proteolysis, affects both the flavour and the consistency of the final cheese. It is especially apparent in Limburger and some blue-mold ripened cheeses. Surface-mold ripened cheeses, such as Brie, rely on enzymes produced by the white *Penicillium camemberti* mold to break down proteins from the outside. When lipids are broken down (as in Parmesan and Romano cheeses), the process is called lipolysis.

Secondary fermentation

The eyes, or holes, typical of Swiss-type cheeses such as Emmentaler and Gruyère come from a secondary fermentation that takes place when, after two weeks, the cheeses are moved from refrigerated curing to a warmer room, where temperatures are in the range of 20° to 24° C (68° to 75° F). At this stage, residual lactates provide a suitable medium for propionic acid bacteria (*Propionibacterium shermanii*) to grow and generate carbon dioxide gas. Eye formation takes three to six weeks. Warm-room curing is stopped when the wheels develop a rounded surface and the echo of holes can be heard when the cheese is thumped. The cheese is then moved back to a cold room, where it is aged at about 7° C (45° F) for 4 to 12 months in order to develop its typical sweet, nutty flavour.

The unique ripening of blue-veined cheeses comes from the mold spores *Penicillium roqueforti* or *P. glaucum,* which are added to the milk or to the curds before pressing and are activated by air. Air is introduced by "needling" the cheese with a device that punches about 50 small holes into the top. These air passages allow mold spores to grow vegetative cells and spread their greenish blue mycelia, or threadlike structures, through the cheese. *Penicillium* molds are also rich in proteolytic and lipolytic enzymes, so that during ripening a variety of trace compounds also are produced, such as free amines, amino acids, carbonyls, and fatty acids—all of which ultimately affect the flavour and texture of the cheese.

Surface-ripened cheeses such as Gruyère, brick, Port Salut, and Limburger derive their flavour from both internal ripening and the surface environment. For instance,

Table 11: Varieties of Cheese, Classified by Hardness and Ripening Method

	ripening method	cheese variety
Very hard	bacteria/enzymes	Asiago, Parmesan, Romano, Sapsago, Sonoma Dry Jack
Hard	bacteria/enzymes	Cantal, cheddar, Colby
	eye-producing bacteria/enzymes	Emmentaler (Swiss), Gruyère, Fontina, Jarlsberg
Semihard/semisoft	bacteria/enzymes	brick, Edam, Gouda, Monterey Jack, mozzarella, Munster, provolone
	bacteria/enzymes and surface microorganisms	Bel Paese, brick, Limburger, Port Salut, Trappist
	bacteria/enzymes and blue mold	blue, Gorgonzola, Roquefort, Stilton
Soft	bacteria/enzymes and surface microorganisms	Brie, Camembert, Neufchâtel (France), Pont l'Évêque
	unripened	baker's, cottage, cream, feta, Neufchâtel (United States), pot

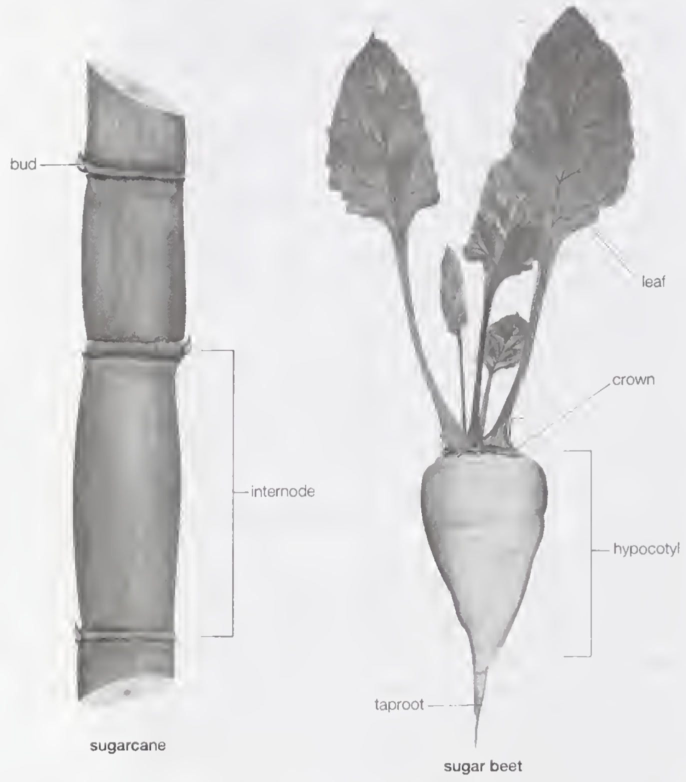

Figure 31: Structures of the sugarcane (left) and sugar beet (right).
Encyclopædia Britannica, Inc.

the high-moisture wiping of the surface of Gruyère gives that cheese a fuller flavour than its Emmentaler counterpart. Specific organisms, such as *Brevibacterium linens,* in Limburger cheese result in a reddish brown surface growth and the breakdown of protein to amino nitrogen. The resulting odour is offensive to some, but the flavour and texture of the cheese are pleasing to many.

Not all cheeses are ripened. Cottage, cream, ricotta, and most mozzarella cheeses are ready for sale as soon as they are made. All these cheeses have sweet, delicate flavours and often are combined with other foods.

Varieties of cheese. As a result of the many combinations of milks, cultures, enzymes, molds, and technical processes, literally hundreds of varieties of cheese are made throughout the world. The different types of cheese can be classified in many ways; the most effective is probably according to hardness or ripening method. Table 11 groups several varieties of cheese based on these criteria.

In recent years different types of cheese have been combined in order to increase variety and consumer interest. For example, soft and mildly flavoured Brie is combined with a more pungent semisoft cheese such as blue or Gorgonzola. The resulting "Blue-Brie" has a bloomy white edible rind, while its interior is marbled with blue *Penicillium roqueforti* mold. The cheese is marketed under various names such as Bavarian Blue, Cambazola, Lymeswold, and Saga Blue. Another combination cheese is Norwegian Jarlsberg. This cheese results from a marriage of the cultures and manufacturing procedures for Dutch Gouda and Swiss Emmentaler.

Pasteurized process cheese. Some natural cheese is made into process cheese, a product in which complete ripening is halted by heat. The resulting product has an indefinite shelf life. Most process cheese is used in food service outlets and other applications where convenient, uniform melting is required.

Process cheeses and process cheese foods

Pasteurized process cheese is made by grinding and mixing natural cheese with other ingredients, such as water, emulsifying agents, colouring, fruits, vegetables, or meat. The mixture is then heated to temperatures of 165° F (74° C) and stirred into a homogeneous, plastic mass. Process cheese foods, spreads, and products differ from process cheese in that they may contain other ingredients, such as nonfat dry milk, cheese whey, and whey protein concentrates, as well as additional amounts of water.

American cheddar is processed most frequently. However, other cheeses such as washed-curd, Colby, Swiss, Gruyère, and Limburger are similarly processed. In a slight variation, cold pack or club cheese is made by grinding and mixing together one or more varieties of cheese without heat. This cheese food may contain added flavours or ingredients. (D.K.B.)

Sugar

Sugar is the common name for sucrose, a crystalline tabletop and industrial sweetener used in foods and beverages. As a chemical term, "sugar" usually refers to all carbohydrates of the general formula $C_n(H_2O)_n$. Sucrose is a disaccharide, or double sugar, being composed of one molecule of glucose linked to one molecule of fructose. Because one molecule of water (H_2O) is lost in the condensation reaction linking glucose to fructose, sucrose is represented by the formula $C_{12}H_{22}O_{11}$ (following the general formula $C_n[H_2O]_{n-1}$).

Sucrose is found in almost all plants, but it occurs at concentrations high enough for economic recovery only in sugarcane (*Saccharum officinarum*) and sugar beets (*Beta vulgaris*). The former is a giant grass growing in tropical and subtropical areas; the latter is a root crop growing in temperate zones (see Figure 31). Sugarcane ranges from 7 to 18 percent sugar by weight, while sugar beets are from 8 to 22 percent sugar by weight. Sucrose from either source (or from two relatively minor sources, the sugar maple tree and the date palm) is the same molecule, yielding 3.94 calories per gram as do all carbohydrates. Differences in sugar products come from other components isolated with sucrose.

Sugar content of cane and beet

The first cultivated sugar crop was sugarcane, developed from wild varieties in the East Indies—probably New Guinea. The sugar beet was developed as a crop in Europe in the 19th century during the Napoleonic Wars, when France sought an alternate homegrown source of sugar in order to save its ships from running blockades to sugarcane sources in the Caribbean. Sugarcane, once harvested, cannot be stored because of sucrose decomposition. For this reason, cane sugar is generally produced in two stages, manufacture of raw sugar taking place in the cane-growing areas and refining into food products occurring in the sugar-consuming countries. Sugar beets, on the other hand, can be stored and are therefore generally processed in one stage into white sugar.

CANE SUGAR

Cane harvesting and delivery. Sugarcane is generally harvested in the cooler months of the year, although it is harvested year-round in Cuba, the Philippines, Colombia, and other prime areas. As much as two-thirds of the world's cane crop is harvested by hand, using long machetes. Since the 1940s, however, mechanical harvesting has increased. Before or after harvest, the cane is burned in order to drive out rodents and snakes and to burn off leaves and trash that dull knife blades, but environmental considerations are leading to the harvesting of whole unburned cane in several areas.

Harvested cane is transported to the factory by many means, ranging from manual haulage to oxcarts, trucks, railway cars, or barges. The usual economic distance between field and factory is 25 kilometres (15 miles). Minimizing the time between cutting and processing reduces the amount of cane deterioration and encourages a higher sugar yield.

Upon arrival at the factory gate, cane is weighed and sampled for analysis (if factors other than weight are used for payment). Cane is stored in as small amounts and for as short a time as possible in the mill yard. Factories run around the clock, stopping in some areas for only one or two days per month for cleaning. Although payment is usually based on weight and sucrose content, quality factors such as moisture, trash, and fibre content also are included. Payment is generally split, with 60 to 65 percent going to the grower and 35 to 40 percent going to the processor.

Raw sugar manufacture. Sugarcane processing, outlined in Figure 32, is practiced in many variations, but the essential process consists of the following steps: extraction of the cane juice by milling or diffusion, clarification of the juice, concentration of the juice to syrup by evaporation, crystallization of sugar from the syrup, and separation and drying of the crystals.

Juice extraction. After weighing, sugarcane is loaded by hand or crane onto a moving table. The table carries the cane into one or two sets of revolving knives, which chop the cane into chips in order to expose the tissue and open the cell structure, thus readying the material for efficient extraction of the juice. Frequently, knives are followed by a shredder, which breaks the chips into shreds for finer cane preparation. The chipped (and shredded) cane then goes through the crusher, a set of roller mills in which the cane cells are crushed and juice extracted. As the crushed cane proceeds through a series of up to eight four-roll mills, it is forced against a countercurrent of water known as water of maceration or imbibition. Streams of juice extracted from the cane, mixed with maceration water from all mills, are combined into a mixed juice called dilute juice. Juice from the last mill in the series (which does not receive a current of maceration water) is called residual juice.

Dilute juice

The alternative to extraction by milling is extraction by diffusion. In this process, cane prepared by rotating knives and a shredder is moved through a multicell, countercurrent diffuser. Extraction of sugar is higher by diffusion (an average rate of 93 percent, compared with 85–90 percent by milling), but extraction of nonsugars is also higher. Diffusion, therefore, is most used where cane quality is highest—*e.g.,* in South Africa, Australia, and Hawaii. Occasionally a smaller "bagasse diffuser" is used in order to increase extraction from partially milled cane after two or three mills. (Residual cane fibre, after juice is removed, is called bagasse.)

Disposal of the large amounts of water used by diffusers is a costly environmental problem, as cane factories that practice diffusion must operate their own primary, secondary, and tertiary water-treatment systems.

Clarification. Mixed juice from the extraction mills or diffuser is purified by addition of heat, lime, and flocculation aids. The lime is a suspension of calcium hydroxide,

often in a sucrose solution, which forms a calcium saccharate compound. The heat and lime kill enzymes in the juice and increase pH from a natural acid level of 5.0–6.5 to a neutral pH. Control of pH is important throughout sugar manufacture because sucrose inverts, or hydrolyzes, to its components glucose and fructose at acid pH (less than 7.0), and all three sugars decompose quickly at high pH (greater than 11.5).

Heated to 99°–104° C (210°–220° F), the neutralized juice is inoculated, if necessary, with flocculants such as polyacrylamides and pumped to a continuous clarification vessel, a large, enclosed, heated tank in which clear juice flows off the upper part while muds settle below. This settling and separation process is known as defecation. Muds are pumped to rotary vacuum filters, where residual sucrose is washed out with a water spray on a rotating filter. Clarified juice, meanwhile, is pumped to a series of three to five multiple-effect evaporators.

Multiple-effect evaporators

Concentration. In the multiple-effect system, developed for the American sugar industry in 1843, steam is used to heat the first of a series of evaporators. The juice is boiled and drawn to the next evaporator, which is heated by vapour from the first evaporator. The process continues through the series until the clarified juice, which consists of 10–15 percent sucrose, is concentrated to evaporator syrup, consisting of 55–59 percent sucrose and 60–65 percent by weight total solids. Nonsugars deposit on the walls and tubes of the evaporators, creating scale deposits and reducing the efficiency of heat transfer. Scale removal often forces the entire factory operation to shut down if another set of evaporators is not available.

Crystallization. Syrup from the evaporators is sent to vacuum pans, where it is further evaporated, under vacuum, to supersaturation. Fine seed crystals are added, and the sugar "mother liquor" yields a solid precipitate of about 50 percent by weight crystalline sugar. Crystallization is a serial process. The first crystallization, yielding A sugar or A strike, leaves a residual mother liquor known as A molasses. The A molasses is concentrated to yield a B strike, and the low-grade B molasses is concentrated to yield C sugar and final molasses, or blackstrap. Blackstrap contains approximately 25 percent sucrose and 20 percent invert (glucose and fructose); at these levels the sugar cannot be removed economically by crystallization.

Crystal separation and drying. Crystals and mother liquor are separated in basket-type centrifuges. Continuous machines are used for C and sometimes B sugars, but batch machines are best for A sugars because of the crystal breakage that takes place in continuous centrifuges. Mother liquor is spun off the crystals, and a fine jet of water is sprayed on the sugar pressed against the wall of the centrifugal basket, reducing the syrup coating on each crystal. In modern factories, the washing process is quite extensive in an effort to produce high-purity raw sugar. Overall recovery of sugar from cane juice averages between 70 and 80 percent.

The washed sugar, dumped from the baskets onto moving belts, dries and cools on the belts as it moves to bulk storage. At this point it is pale brown to golden yellow, with a sucrose content of 97–99 percent and a moisture content of 0.5 percent. This raw sugar, the sugar of commerce, is stored in bags in countries where labour is abundant and cheap. Generally, however, it is stored in bulk and shipped loose, like grain, in dry-bulk ships to areas where it will be refined.

Raw sugar products. *Open pan sugar.* In industrial sugarcane processing, crystallization is conducted under vacuum in order to lower operating temperatures, but some sugar is produced in the tropics by "open pan" processes. In these processes, crudely clarified juices are boiled down in opcn containers until a sludgy mass of crystals can be transferred to molds. The hardened brown product is sold as *panela* or *piloncillo* in Latin America and as *gur* or *khansari* in Asia.

Plantation white sugar. Plantation white, or mill white, sugar is a white sugar commonly produced for local consumption in sugarcane-growing countries. It is produced at the factory without remelting and refining of the raw sugar. Instead, sulfur dioxide gas (produced by burning sulfur in air) is injected into extracted juice, where it bleaches juice colorants, is oxidized to sulfate, and then is neutralized by the addition of lime. (Sulfite salts are sometimes substituted for sulfur dioxide.) A white sugar results that is suitable for table use but not for food processing, because it contains all the nonsugars (including bleached or reduced colorant) present in raw sugar.

Bleaching unrefined sugar

Higher grades of plantation white are produced by a carbonatation purification process, in which carbon dioxide gas (scrubbed flue gas) is injected into juice and reacted with lime to form calcium carbonate, which absorbs and adsorbs nonsugars and is filtered off. Powdered vegetable carbon is sometimes added to increase decolorization.

As demand for high-quality white sugars increases among food processors and beverage manufacturers in tropical areas, the processes described above are being improved and replaced by "Blanco Directo" processes, in which colour-precipitating reagents remove colorants instead of temporarily bleaching them.

Sugar refining. Sugar refining is the production of high-quality sugars from remelted raw cane sugars. ("Refining" is also used in beet sugar factories to describe the remelting and recrystallization processes by which high-quality white sugars are made from lower-grade beet syrups; see below *Beet sugar.*) About 35 percent of cane sugar is refined; the remainder is consumed as plantation white or as raw sugar. In tropical regions, small "white end" refineries are often built to refine the raw sugar produced by cane-processing plants. Raw sugar factories produce their own steam by burning bagasse, and a reasonably efficient plant has as much as 20 percent excess bagasse. This can be burned to operate the white end refinery, or it can be used to run a distillery or even generate electricity to be sold to the local power grid.

Still, most sugar refining is conducted in the consuming regions by large refineries, which produce a range of products such as soft brown sugars, sugar cubes, and granulated sugar. At these refineries, the raw sugar is affined (washed), melted (dissolved), sent through processes of clarification and decolorization, and crystallized. Sugar products are then dried, packaged, and stored.

Affination and melting. Affination is the mingling of raw sugar with a warm, heavy syrup, which removes the molasses coating from the sugar crystal. The syrup and crystals are separated in a spinning centrifugal basket, and the crystals are further "washed" by a water spray. Washed raw sugar is fed by screw conveyor to a melter, where it is dissolved at 65° C (150° F) in hot, sweet water with some fresh, hot water added to obtain a raw liquor containing about 65 percent dissolved solids.

Clarification and decolorization. Melt syrup is clarified either by phosphatation, in which phosphoric acid and lime are added to form calcium phosphates, which are removed by surface scraping in a flotation clarifier, or by carbonatation, in which carbon dioxide gas and lime form calcium carbonate, which is filtered off. Colour precipitants are added to each process.

The carbonatated liquors are filtered in pressure leaf filters with the use of diatomaceous earth, a filter aid invented for sugar processing. The resultant yellow to light brown liquor is further decolorized by carbon adsorbents, such as granular activated carbon or bone charcoal, or by ion-exchange resins of acrylic or styrenic materials. Decolorization is conducted in columns in various serial or parallel conformations.

Crystallization. Fine clarified liquor is boiled to white sugar in a series of vacuum pans similar to those used in sugarcane processing. The boiling system is complicated because the purity of the fine liquor is more than 98 percent, and at least six or seven stages of boiling are necessary before the molasses is exhausted. The first three or four strikes are blended to make commercial white sugar. Special large-grain sugar (for bakery and confectionery) is boiled separately. Fine grains (sanding or fruit sugars) are usually made by sieving products of mixed grain size. Powdered icing sugar, or confectioners' sugar, results when white granulated sugar is finely ground, sieved, and mixed with small quantities (3 percent) of starch or calcium phosphate to keep it dry. Brown sugars (light to dark) are

Large-grain, fine-grain, and powdered sugar either crystallized from a mixture of brown and yellow syrups (with caramel added for darkest colour) or made by coating white crystals with a brown-sugar syrup.

Packaging and storage. Crystalline and liquid sucrose products are dried and packaged in food-grade packaging plants. Package sizes range from individual servings to one-ton bags, packaging materials from paper to plastic-lined burlap or fabric. Sugar cubes are made by mixing white (or brown) sugar with syrup and then molding and drying.

Refineries can also produce syrups in a range of colours and flavours for the food-processing industry. Products include liquid sucrose as well as invert syrups (syrups containing all or partially inverted sucrose).

BEET SUGAR

Beet sugar factories generally produce only white sugar from sugar beets. Brown sugars are made with the use of cane molasses as a mother liquor component or as a crystal coating.

Sugar beet harvest and delivery. Sugar beets are grown in temperate areas of Europe, North America, and northern Asia. They are harvested from September through November, almost always by multirow harvester machines. The machines remove some dirt, the leaves, and sometimes the crown (depending on the contract terms). Because sugar does not deteriorate as severely in beets as it does in sugarcane shortly after harvest, a full crop of beets can be lifted (harvested) and stored for several weeks at ambient temperature or even for several months at freezing temperatures.

Beets are delivered by rail or road transport to the factory, where they are weighed in and sampled for analysis. Sampling schemes vary in complexity; beets are analyzed for trash, soil, sugar content, and (where beet quality is part of the contract) nitrogen and salt content. Sugar beet, being a root, has a much higher nitrogen content than sugarcane, and these nitrogen compounds can affect certain processing steps.

Payment is split along lines similar to lines for sugarcane payment, 60–65 percent going to the grower and 35–40 percent to the factory.

White sugar production. *Washing and extraction.* When harvested sugar beets are off-loaded at the factory, they are washed in a flume to remove rocks and dirt and then fed by gravity through a hopper to the slicing machine. There the roots are cut into "cossettes," V-shaped strips, three by four to seven centimetres in size (approximately one by two to three inches) in order to offer maximum surface area for extraction. Sugar extraction takes place in a multicell countercurrent diffuser. In order to minimize microbial growth and the use of biocide, temperatures are maintained above 75° C (167° F). Some 98 percent of the sugar is extracted to form what is known as diffusion juice, or raw juice.

Remaining beet pulp, discharged at over 90 percent moisture content, is pressed and dried. Pulp driers are a major energy consumer at the beet factory, which must purchase fuel since pulp cannot be burned and has a high market value as feed.

From raw juice to clear juice

Purification. Raw juice (containing 10 to 14 percent sucrose) is purified in a series of liming and carbonatation steps, often with filtration or thickening being conducted between the first and second carbonatation. One popular multistage system involves cold pre-liming followed by cold main liming, hot main liming, first carbonatation, filtration and mud recirculating, addition of heat and soda, second carbonatation, and filtration.

After carbonatation, sulfur dioxide is pumped through the juice in order to lower the pH level and reduce the colour. Beet processing is generally at pH levels slightly above 7. At low pH, invert sugar would form and react with nitrogen compounds to form colour, and, at high pH, alkaline destruction of sucrose and monosaccharides would occur.

Concentration and crystallization. After purification, the juice, now called clear or thin juice, is pumped to multiple-effect evaporators similar to those used in raw cane sugar manufacture. In the evaporators the juice is concentrated to thick juice (60–65 percent dissolved solids), which is mixed with remelted lower grades of sugar to form standard liquor. From this standard liquor, sugar is crystallized, usually in three stages. In all boiling systems, sugar obtained from the first stage is processed as a final product, while sugar from the second and third stages is remelted and recycled into another batch of thick juice.

Sugar is separated from mother liquor in basket centrifuges, and it is dried in either rotary louvred driers or fluidized-bed dryer-coolers.

Packaging and storing. Before packing, it is important that all sugar be cooled below 45° C (113° F). At higher temperatures it hardens in the bag or silo and can develop colour. Beet sugar factories store white sugar in silos during production and pack sugar year-round to meet the current market.

Molasses processing. In order to increase production at the beet sugar factory, molasses desugarization is practiced. One prominent desugarization process is ion exclusion, which separates compounds by their molecular weight and electrical charge. A fraction containing salts and high-molecular-weight colorants and saccharides comes first off the resin column; then comes a sucrose fraction, and then a betaine fraction (trimethylglycine, a component of sugar beets), which may be sold as a separate product. The sucrose fraction is recycled into thick juice to form standard liquor. Ion-exchange processes reduce residual sucrose in molasses to 9–14 percent and increase a factory's overall yield by 10 percent.

SUGAR BY-PRODUCTS

By-products of cane sugar and beet sugar production include fibre (from both cane and beet) and molasses (residual concentrated syrup from which no more sugar can economically be removed).

Fibre. *Sugar beet pulp.* Sugar beet pulp is used almost entirely for animal feed, mixed with molasses in loose or pellet form. Because of the higher nitrogen content of sugar beets, nitrogen (in the form of urea) need not be added, as it must when sugarcane bagasse is used for animal feed. Other uses for beet pulp are as edible fibre, for addition of soluble fibre to baked goods and processed foods, and for inclusion in paper manufacture.

Bagasse. Feed use for bagasse is relatively minor. The major use is as fuel for the cane factory, where one ton of dry bagasse is equivalent in energy value to two barrels of fuel oil. Freshly produced bagasse contains about 50 percent moisture and becomes drier on storage.

Bagasse is also widely used as filler for paper, fibreboard, and particleboard—especially in areas where wood is in short supply. Paper quality ranges from kraft-process brown paper through newsprint to glossy white.

Molasses. Molasses from both sugarcane and sugar beets is a major component of animal feed. Sugar beet molasses that has been subjected to desugarization contains reduced carbohydrate levels and may be blended with cane molasses.

Production of ethanol (ethyl alcohol) for industry and distilled spirits is common at most cane and beet factories. Rum is produced from cane molasses in the Western Hemisphere; beverage alcohol is produced from beet molasses in Europe. (M.A.C.)

Cocoa products

The cocoa bean is the seed of the cacao tree (*Theobroma cacao*), a tropical plant indigenous to the equatorial regions of the Americas. From the processed cocoa bean comes the fluid paste, or liquor, from which cocoa powder and chocolate are made. Chocolate is sold directly to the consumer as solid bars of eating chocolate, as packaged cocoa, and as baking chocolate. It is also used by confectioners as coating for candy bars and boxed or bulk chocolates, by bakery product manufacturers and bakers as coating for many types of cookies and cakes, and by ice-cream companies as coating for frozen novelties. Cocoa powders, chocolate liquor, and blends of the two are used in bulk to flavour various food products and to provide the flavours in such "chocolate" products as syrups, toppings, chocolate milk, prepared cake mixes, and pharmaceuticals.

HISTORY OF USE

The cacao tree was cultivated more than 3,000 years ago by the Maya, Toltec, and Aztec, who prepared a beverage from the bean (sometimes using it as a ceremonial drink) and also used the bean as a currency.

Early uses of cocoa

Columbus brought cocoa beans to Spain after his fourth voyage in 1502, and the Spanish conquistadores, arriving in Mexico in 1519, were introduced to a chocolate beverage by the Aztec. The Aztec beverage was made from sun-dried shelled beans, probably fermented in their pods. The broken kernels, or nibs, were roasted in earthen pots, then ground to paste in a concave stone, called a *metate*, over a small fire. Vanilla and various spices and herbs were added, and corn (maize) was sometimes used to produce milder flavour. The paste, formed into small cakes, was cooled and hardened on shiny leaves placed under a tree. The cakes were broken up, mixed with hot water, and beaten to foamy consistency with a small wooden beater, a molinet, producing the beverage called *xocoatl* (from Nahuatl words meaning "bitter water").

Too bitter for European taste, the mixture was sweetened with sugar when introduced to the Spanish court. Although Spain guarded the secret of its *xocoatl* beverage for almost 100 years, it reached Italy in 1606 and became popular in France with the marriage of the Spanish princess Maria Theresa to Louis XIV in 1660. In 1657 a Frenchman opened a London shop, selling solid chocolate to be made into the beverage, and chocolate houses, selling the hot beverage, soon appeared throughout Europe. By 1765 chocolate manufacture began in the American colonies at Dorchester, in Massachusetts, using cocoa beans from the West Indies.

In 1828 C.J. van Houten of The Netherlands patented a process for obtaining "chocolate powder" by pressing much of the cocoa butter from ground and roasted cocoa beans. In 1847 the English firm of Fry and Sons combined cocoa butter, a by-product of the pressing, with chocolate liquor and sugar to produce eating chocolate, and in 1876 Daniel Peter of Switzerland added dried milk to make milk chocolate. The proliferation of flavoured, solid, and coated chocolate foods rapidly followed.

Starting in the Americas in an area stretching from southern Mexico to the northern countries of South America, commercial cacao cultivation spread around the world to areas within 20° of the Equator where rainfall, temperatures, and soil conditions were suitable for its growth.

COCOA BEAN PROCESSING

Harvesting. Harvesting of cocoa beans can proceed all year, but the bulk of the crop is gathered in two flush periods occurring from October to February and from May to August. The ripe seed pods are cut from the trees and split open with machetes. The beans, removed from the pods with their surrounding pulp, are accumulated in leaf-covered heaps, in leaf-lined holes dug in the ground, or in large shallow boxes having perforated bottoms to provide for drainage.

Fermentation. The pulp of common grades (Forastero) is allowed to ferment for five to seven days, and the pulp of the more distinctively flavoured grades (Criollo) for one to three days. Frequent turnings dissipate excess heat and provide uniformity. During fermentation, the juicy sweatings of the pulp are drained away, the germ in the seed is killed by the increased heat, and flavour development begins. The beans become plump and full of moisture, and the interior develops a reddish brown colour and a heavy, sharp fragrance. The fermented beans are sun-dried or kiln-dried to reduce moisture content to 6–7 percent and bagged for shipment.

Cleaning, roasting, and grinding. Cocoa beans are subjected to various cleaning processes to remove such contaminants as twigs, stones, and dust. Roasting develops flavour, reduces acidity and astringency, lowers moisture content, deepens colour, and facilitates shell removal. After roasting comes a cracking and fanning (winnowing) process, in which machines crack the shells and then separate them from the heavier nibs by means of blowers. The cell walls of the nibs are in turn broken by grinding, releasing the fat, or cocoa butter, and forming a paste called chocolate liquor, or cocoa mass. If alkalized (Dutched) chocolate liquor is to be produced, the cocoa beans may be winnowed raw; the raw nibs will be alkalized and then roasted prior to grinding.

Conching. Conching, a flavour-developing, aerating, and emulsifying procedure performed by conche machines, requires from 4 to 72 hours, depending on the results desired and the machine type. Temperatures used in this process range from 55° to 88° C (130° to 190° F) and are closely controlled to obtain the desired flavour and uniformity.

Molding. In molding, the chocolate is cast in small consumer-size bars or in blocks weighing about 10 pounds for use by confectioners, then subjected to cold air to produce hardening.

COCOA BEAN PRODUCTS

Cocoa powders. Cocoa powders are produced by pulverizing cocoa cakes, made by subjecting the chocolate liquor of about 53 to 56 percent cocoa butter content to hydraulic pressing to remove a predetermined amount of cocoa butter. The cocoa butter content remaining in the powder may range from 8 to 36 percent, with the most common commercial grades in the United States containing 11, 17, or 22 percent cocoa butter. In the United Kingdom, cocoa sold for beverage use must contain a minimum of 20 percent.

Cocoa butter content

Natural process. Natural-process cocoa powders and chocolate liquors receive no alkali treatment. Cocoa beans are normally slightly acid, with a pH of 5.2–5.8. When the pH remains unchanged, the beans produce pleasantly sharp flavours blending well in many foods and confections.

Dutch process. Dutch-process cocoa powders and chocolate liquors are treated at the nib, liquor, or powder stage. The treatment is frequently referred to as "Dutching" because the process, first applied by C.J. van Houten in The Netherlands, was introduced as "Dutch cocoa." In this alkalizing process, a food-grade alkali solution may be applied in order partially to neutralize the natural cocoa acids, mostly acetic acid like that in vinegar; or it may be used to produce a strictly alkaline product, with a pH as high as 8.0. Potassium carbonate is most commonly used as an alkalizer, although other alkalies, such as sodium carbonate, may be used. In addition to altering the pH of the cocoa powder, the process darkens colour, mellows flavour, and alters taste characteristics.

Chocolate products. Chocolate products usually require the addition of more cocoa butter to that already existing in the chocolate liquor. The various forms of chocolate are available in consumer-size packages and in large bulk sizes for use by food manufacturers and confectioners. Most European confectioners make their own chocolate; other confectioners buy chocolate from chocolate-manufacturing specialists. For large commercial orders, chocolate is shipped, warm and in liquid form, in heated sanitary tank trucks or tank cars.

Baking chocolate. Baking (bitter) chocolate, popular for household baking, is pure chocolate liquor made from finely ground nibs, the broken pieces of roasted, shelled cocoa beans. This chocolate, bitter because it contains no sugar, can be either the natural or alkalized type.

Sweet chocolate. Sweet chocolate, usually dark in colour, is made with chocolate liquor, sugar, added cocoa butter, and such flavourings as vanilla beans, vanillin, salt, spices, and essential oils. Sweet chocolate usually contains at least 15 percent chocolate liquor content, and most sweet chocolate contains 25–35 percent. The ingredients are blended, refined (ground to a smooth mass), and conched. Viscosity is then adjusted by the addition of more cocoa butter, lecithin (an emulsifier), or a combination of both.

Milk chocolate. Milk chocolate is formulated by substituting whole milk solids for a portion of the chocolate liquor used in producing sweet chocolate. It usually contains at least 10 percent chocolate liquor and 12 percent whole milk solids. Manufacturers usually exceed these values, frequently going to 12–15 percent chocolate liquor and 15–20 percent whole milk solids. Milk chocolate, usually lighter in colour than sweet chocolate, is sweeter or milder in taste because of its lower content of bitter chocolate liquor. Processing is similar to that of sweet chocolate. "Bitter chocolate" refers to either baking chocolate or bittersweet chocolate. Bittersweet is similar to sweet chocolate but contains less sugar and more chocolate liquor. Minimum percentages of chocolate liquor are fixed by law in some countries, such as the United States.

Chocolate-type coatings. Confectionery coatings are made in the same manner as similar chocolate types, but some or all of the chocolate liquor is replaced with equivalent amounts of cocoa powder, and instead of added cocoa butter, with a melting point of about 32°–33° C (90°–92° F), other vegetable fats of equal or higher melting points are used. In the United States the legal name of this coating is "sweet cocoa and vegetable fat (other than cocoa fat) coatings." In the "chocolate" coating usually applied to ice cream and other frozen novelties, legally known as "sweet chocolate and vegetable fat (other than cocoa fat) coatings," the added cocoa butter usual in chocolate is replaced by lower-melting-point vegetable fats, such as coconut oil.

By-products. Shells, the major by-product of cocoa and chocolate manufacturing, represent 8–10 percent of raw cocoa bean weight and are blown off in the cracking and fanning, or winnowing, operation. They are used for fertilizer, mulch, and fuel.

Chocolate and cocoa grades. In chocolate and cocoa products, there is no sharp difference from one grade or quality to the next. Chocolate quality depends on such factors as the blend of beans used, with about 20 commercial grades from which to choose; the kind and amount of milk or other ingredients included; and the kind and degree of roasting, refining, conching, or other type of processing employed. Chocolate and cocoa products are only roughly classified; there are hundreds of variations on the market, alone or in combination with other foods or confections.

Care and storage. Chocolate and cocoa require storage at 18°–20° C (65°–68° F), with relative humidity below 50 percent. High (27°–32° C, or 80°–90° F) or widely fluctuating temperatures will causc fat bloom, a condition in which cocoa butter infiltrates to the surface, turning products gray or white as it recrystallizes.

Fat bloom and mustiness

High humidity causes mustiness in cocoa powder and can lead to mold formation in cocoa powder or on chocolate. Excessive moisture can also dissolve sugar out of chocolate, redepositing it on the surface as sugar bloom, distinguished from fat bloom by its sandy texture.

Nutritive value. Cocoa, a highly concentrated food providing approximately 1,000 calories per kilogram, provides carbohydrates, fat, protein, and minerals. Its theobromine and caffeine content produce a mildly stimulating effect. The carbohydrates and easily digested fats in chocolate make it an excellent high-energy food. (L.R.C./Ed.)

Confectionery products

The application of the terms confectionery and candy varies among English-speaking countries. In the United States candy refers to both chocolate products and sugar-based confections; elsewhere "chocolate confectionery" refers to chocolates, "sugar confectionery" to the various sugar-based products, and "flour confectionery" to such products as cakes and pastries. This section is primarily concerned with sugar confectionery. Other types of confections are discussed in the sections *Bakery products* and *Cocoa products.*

HISTORY

Egyptian hieroglyphics dating back at least 3,000 years indicate that the art of sugar confectionery was already established. The confectioner was regarded as a skilled craftsman by the Romans, and a confectioner's kitchen excavated at Herculaneum was equipped with pots, pans, and other implements similar to those in use today.

Early confectioners, not having sugar, used honey as a sweetener and mixed it with various fruits, nuts, herbs, and spices.

During the Middle Ages the Persians spread sugarcane cultivation, developed refining methods, and began to make a sugar-based candy. A small amount of sugar was available in Europe during the Middle Ages and was used in the manufacture of the confections prepared and sold mainly by apothecaries. The Venetians brought about a major change in candy manufacture during the 14th century, when they began to import sugar from Arabia. By the 16th century confectioners were manufacturing sweets by molding boiled sugar with fruits and nuts into fanciful forms by simple hand methods. The development of candy-manufacturing machinery began in the late 18th century.

INGREDIENTS

Sweeteners. Sugar, mainly sucrose from sugar beets or sugarcane, is the major constituent of most candies. Other sweeteners employed in candy manufacture include corn syrup, corn sugar, honey, molasses, maple sugar, and noncaloric sweeteners. Sweeteners may be used in dry or liquid form.

Invert sugar

Invert sugar, a mixture of glucose (dextrose) and fructose produced from sugar (sucrose) by application of heat and an acid "sugar doctor," such as cream of tartar or citric acid, affects the sweetness, solubility, and amount of crystallization in candymaking. Invert sugar is also prepared as a syrup of about 75 percent concentration by the action of acid or enzymes on sugar in solution.

Texturizers and flavourings. Because of the perishability of fresh fluid milk and milk products, milk is usually used in concentrated or dried form. It contributes to candy flavour, colour, and texture. Fats, usually of vegetable origin, are primarily used to supply textural and "mouth feel" propcrtics (lubrication and smoothness). They arc also used to control crystallization and to impart plasticity. Such colloids as gelatin, pectin, and egg albumin are employed as emulsifying agents, maintaining fat distribution and providing aeration. Other ingredients include fruits; nuts; natural, fortified, and artificial flavours; and colourings.

PRODUCTS

Candies can be divided into noncrystalline, or amorphous, and crystalline typcs. Noncrystallinc candies, such as hard candies, caramels, and toffces, are chcwy or hard, with homogeneous structure. Crystalline candies, such as fondant and fudgc, are smooth, creamy, and easily chewed, with a dcfinite structurc of small crystals.

High-boiled, or hard, candy. *Properties.* Sugar has the property of forming a type of noncrystallinc "glass" that forms the basis of hard candy products. Sugar and water are boiled until the concentration of the solution reaches a high level, and supersaturation persists upon cooling. This solution takes a plastic form and on further cooling becomes a hard, transparent, glassy mass containing lcss than 2 percent watcr.

Precisc control of boiling

High-boiled sugar solutions are unstable, however, and will readily crystallize unless prcventative stcps are taken. Control of modern sugar-boiling processes is precise. Crystallization is prcvcnted by adding either manufactured invert sugar or corn syrup. The latter is now favoured because it contains complex saccharides and dextrins that, in addition to increasing solubility, give greater viscosity, considerably retarding crystallization.

Hard candy manufacture. Originally, hard candy syrups were boiled ovcr a coke or gas fire. Modern manufacturers use pans jacketed with high-pressure steam for batch boiling. Special steam-pressure cookers through which syrup passes continuously are used when a constant supply is required. For flavouring and colouring, thc batch of boiled syrup is turned out on a table to cool. While still plastic, the ingredients are kncaded into the batch; this may be done mechanically. In continuous production, flavours may be added to the hot liquid syrup. Especially prepared "sealed" flavours are then required to prevent loss by evaporation.

After flavouring, the plastic mass is shaped by passing through rollers with impressions or through continuous forming machines that produce a "rope" of plastic sugar.

By feeding a soft filling into the rope as a core, "bonbons" are made.

A satinlike finish may be obtained by "pulling" the plastic sugar. This consists of stretching the plastic mass on rotating arms and at the same time repeatedly overlapping. With suitable ratios of sugar to corn syrup, pulling will bring about partial crystallization and a short, spongy texture will result.

Caramels and toffee. The manufacture of caramel and toffee resembles hard candy making except that milk and fat are added. Sweetened, condensed, or evaporated milk is usually employed. Fats may be either butter or vegetable oil, preferably emulsified with milk or with milk and some of the syrup before being added to the whole batch. Emulsifiers such as lecithin or glyceryl monostearate are particularly valuable in continuous processes. The final moisture content of toffee and particularly of caramels is higher than that of hard candy. Because milk and fat are present, the texture is plastic at normal temperatures. The action of heat on the milk solids, in conjunction with the sugar ingredients, imparts the typical flavour and colour to these candies. This process is termed caramelization.

Because caramel is plastic at lower temperatures than hard candy, it may be extruded. Machines eject the plastic caramel under pressure from a row of orifices; the resulting "ropes" are then cut into lengths. Under continuous manufacturing, all ingredients are metred in recipe quantities into a container that gives an initial boil. Then the mixed syrup is pumped first into a continuous cooker that reduces the moisture content to its final level, and finally into a temporary holding vessel in which increased caramelization occurs, permitting the flavour obtained by the batch process to be matched. The cooked caramel is then cooled, extruded, and cut.

Fondant. Fondant, the basis of most chocolate-covered and crystallized crèmes (which themselves are sometimes called "fondants"), is made by mechanically beating a solution supersaturated with sugar, so that minute sugar crystals are deposited throughout the remaining syrup phase. These form an opaque, white, smooth paste that can be melted, flavoured, and coloured. Syrup made from corn syrup and sugar is now generally used for fondant.

Continuous production of fondant

Fully mechanical plants produce a ton of fondant per hour. Syrup, produced in a continuous cooker, is delivered to a rotating drum (see Figure 33) that is cooled internally with water sprays. The cooled syrup is scraped from the drum and delivered to a beater consisting of a water-cooled, rectangular box fitted internally with rotating pegged spindles and baffles. This gives maximum agitation while the syrup is cooling, causing very fine sugar crystals to be deposited in the syrup phase. The crystals, together with a small amount of air entrapped by the beating, give the fondant its typical white opacity. The proportion of sugar to corn syrup in the base syrup usually ranges from 3:1 to 4:1. The moisture content of fondant ranges from 12 to 13 percent.

Mechanically prepared fondant can be reheated without complete solution of the sugar-crystal phase, and it will be sufficiently fluid to be cast into molds. At the same time colourings and flavourings—fruit pulp, jam, essential oils, etc.—may be added. Remelting is usually carried out in steam-jacketed kettles provided with stirrers at a temperature range between 65° and 75° C (145° and 155° F).

Shaped pieces of fondant for crystallizing or covering with chocolate are formed by pouring the hot, melted, flavoured fondant into impressions made in cornstarch. A shallow tray about two inches deep is filled with cornstarch, which is leveled off and slightly compressed. A printing board covered with rows of plaster, wood, or metal models of the desired shape is then pressed into the starch and withdrawn. Into these impressions the fondant is poured and left to cool. Next, the tray is inverted over a sieve; the starch passes through, leaving the fondant pieces on the sieve. After gentle brushing or blowing to remove adhering starch, the fondants are ready for covering or crystallizing. A machine known as a Mogul carries out all these operations automatically, filling trays with starch, printing them, depositing melted fondant, and stacking the filled trays into a pile. At the other end of the machine, piles of trays that contain cooled and set crèmes are unstacked and inverted over sieves, and the crèmes are removed to be brushed and air-blown. Empty trays are automatically refilled, and the cycle continues.

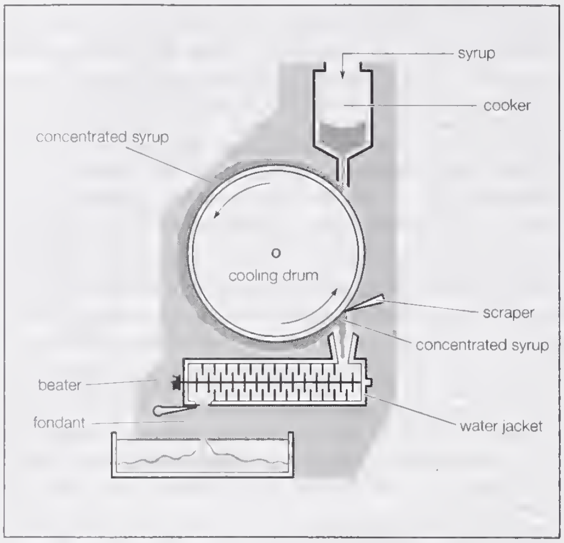

Figure 33: Continuous fondant-making machine.
Encyclopædia Britannica, Inc

Certain types of fondant may be remelted and poured into flexible rubber molds with impressions, but this process generally is limited to shallow crèmes of a fairly rigid consistency. Metal molds precoated with a substance that facilitates release of the crème also are used. The crème units are ejected from the inverted mold by compressed air onto a belt, which takes them forward for chocolate covering.

Fudge. Fudge combines certain properties of caramel with those of fondant. If hot caramel is vigorously mixed or if fondant is added to it, a smooth, crystalline paste forms on cooling. Known as fudge, this substance has a milky flavour similar to caramel and a soft, not plastic, texture. Fudge may be extruded or poured onto tables and cut into shapes. It is possible to construct a recipe that will pour into starch, but such fudge generally is inferior.

(H.B.K./B.W.M./Ed.)

Frozen prepared foods

Frozen prepared foods consist of complete meals or portions of meals that are precooked, assembled into a package, and frozen for retail sale. They are popular among consumers because they provide a diverse menu and are convenient to prepare. A typical frozen prepared meal contains a meat entree, a vegetable, a starch-based food such as pasta, and sauce. The manufacture of such a product requires careful attention by the food processor.

PREPARATION OF MEAL COMPONENTS

Meats. Meats are often one of the major components in a frozen meal. Several processing methods are used in preparing meats, such as marinating, cooking, and cutting or slicing.

Marinating. In order to tenderize the meat and develop desirable sensory attributes, a marinade is often helpful. Typical marinades contain salt, vinegar, lemon juice, spices, citric acid, and oil. Tenderization of meats is particularly enhanced by marinades that contain proteolytic enzymes—that is, enzymes that help to break down proteins. Meats are simply soaked in the marinade, or they are injected with marinade using special injection machines.

Cooking. Cooking of meats is necessary to eliminate all pathogens such as bacteria that produce harmful toxins. In a typical cooking process, the temperature at the centre of the meat is raised to 70° C (160° F) and held for at least two minutes.

Many meats are fried in immersion fryers. During frying, meats are cooked and desirable flavours created. Furthermore, the hot oil used in frying sears the surface of the meat, minimizing moisture loss during cooking. When meats are coated with breading material, frying is helpful in binding the batter. The oil retained in the breading layer enhances the aroma and texture of the fried foods.

Certain delicate foods, such as fish, are breaded and prefried for a short time to bind the breading material. Actual cooking of the fish is done when the consumer reheats the product. On the other hand, fried chicken is completely precooked during the frying process. Frozen fried chicken is reheated mainly to raise the serving temperature.

Commercial fryers

Commercial fryers are either batch or continuous units. In a continuous fryer, the foodstuff is placed on a feed conveyor that moves the product into a tank filled with frying oil. The oil is heated to 170°–180° C (340°–360° F). Simultaneously, another conveyor moves in the same direction just above the feed conveyor in order to prevent the food material from floating in the tank. The speed of the feed conveyor is carefully controlled so that the product remains immersed in oil for the required time. At the end of the tank, the conveyor moves the fried foodstuff above the oil, the surface oil being drained back into the tank.

Oven cooking is another method used to prepare main entrees in frozen prepared meals. Inside an oven, foods are heated by conduction, convection, or radiation. Certain ovens are designed to introduce steam during the heating cycle. In continuous-type ovens, the food moves on a mesh conveyor through different zones where the food may be subjected to different air velocities and steam flow in order to maintain the humidity at a desired level.

Batch-type ovens are ideally suited to cooking under vacuum. In vacuum cooking, meats are cooked at reduced pressure and temperature. In one vacuum technique, known as *sous-vide* cooking, foods are cooked in their own juices, thus retaining their natural flavours and moisture. Cooking time is usually increased because of the low temperatures employed. The process involves placing the food inside a laminated pouch and subjecting the packaged product to vacuum before sealing. The sealed pouch is then cooked in boiling water. After cooking, the pouches are quickly cooled in a stream of cold water prior to freezing.

Slicing and dicing. Cooked meats are more sensitive to physical handling than raw meats, because upon cooking the meat tissues become loosely connected with one another. Therefore, cooked meats are cooled to low temperatures, resulting in the stiffening of the muscle fibres, thus easing the cutting and slicing operations.

When the meats are in frozen state—that is, at temperatures between −18° and −23° C (0° and −10° F)—they are tempered before cutting. Tempering involves warming the frozen meats to temperatures slightly below their freezing point—for example, between −4° and −1° C (25° and 30° F). Tempering of frozen foods is often carried out in industrial-scale microwave ovens.

Meats are cut into cubes or dices by a dicing machine. A common industrial-scale dicer uses a knife blade attached to a revolving impeller. With each revolution of the impeller, the blade removes a slice from the large pieces of meat that are fed to the machine. The meat slices are cut into squares using cross-cut knives. The diced product is then discharged from the machine.

Vegetables. The vegetable portion of a prepared meal may be procured directly from a frozen-food processor, or raw vegetables may be frozen on site. The blanching and freezing of vegetables is described in *Vegetables: Processing of vegetables*. Processed vegetables that are intended for inclusion in prepared foods may be frozen if they are to be stored for a long duration, or they may be directly conveyed to the processing area for assembly on meal trays.

Pasta. In preparing pasta, size is an important criterion. Thin pastas such as spaghetti cook rapidly, so their texture is more difficult to control. Thick pastas, on the other hand, can be heated and cooled in a more controlled manner.

Pastas are cooked in rotary blanchers holding large volumes of water. A gentle rotary action in the blancher helps to avoid clumping during cooking. (Vegetable oil may also be added to the cooking water.) At the end of the cooking cycle, surface starch is washed off the pasta, again to avoid clumping. Immersing the cooked pasta in cold water also stops the cooking process.

Sauce. Sauces and gravies impart desirable sensory attributes to meats and vegetables. Furthermore, they help to prevent undesirable changes that result from dehydration of frozen foods during long-term storage. The most common sauces are either tomato- or cream-based. All sauces are accented with spices, thickening agents, emulsifiers, and salt.

Preparing ingredients. Dry ingredients are weighed and mixed in mixing blenders. The type of blender used depends on the physical characteristics of the ingredient particles and on whether any liquids or shortening agents are to be added to the mix. Complete mixing of the ingredients with the liquids or shortenings is vital to prevent inconsistencies in the final product.

Tomato and cream sauces

Tomato sauce is often made from tomato paste. Tomato paste usually contains from 24 to 36 percent tomato solids. Typically, it is procured in drums or flexible multiwall bags. Water is pumped in to flush out the paste and to help in diluting it to the desired concentration for sauce. The resulting tomato puree is then mixed with other ingredients to prepare the sauce.

Cream-based sauces begin with stock solutions, which are prepared by boiling raw stock material such as beef, fish, or poultry in water. Boiling is conducted in large kettles that may be operated either open to the atmosphere or under vacuum. Boiling under vacuum, accomplished at temperatures lower than 100° C (212° F), helps to retain more flavour compounds in the stock. Salt, spices, and herbs are added during the cooking process. After cooking is completed, the muscle tissue is removed.

Mixing, cooking, and cooling. In preparing sauces, dry mixes and liquids are blended to obtain a well-mixed slurry. The slurry is then fed into a cooking vessel, typically an open steam-jacketed kettle. Kettles may also be fitted with agitators, blenders, or scrapers. The agitator, located on the central axis, moves the product away from the heat-transfer surface of the kettle, an action that provides thorough cooking or cooling of the food material. Sometimes the scraper fingers of the agitator may move the product into the path of a secondary agitator for enhanced blending. Scraping and agitating help to minimize the building up of burned material on the heated surface.

During cooking of sauces, continued heating results in the swelling and gelation of the thickening agents and in the extraction of flavours from the seasoning agents. In order to retain more of the volatile and natural colour pigments, cooking may be done under vacuum.

Cream sauces are usually homogenized after heating. Homogenization ensures that fat globules will retain the small size necessary to stabilize the resulting emulsion. The scraping action must be done at high speed to prevent scorching the product.

After cooking, sauces are cooled rapidly to approximately 4° C (40° F). If the sauces contain only small or no particulates, then plate heat exchangers are used for cooling. In a plate heat exchanger, there is an indirect contact between the sauce and a cooling medium such as chilled water. A countercurrent flow arrangement between the sauce and the cooling medium assures high energy efficiency. After cooling, the sauce is stored in chilled holding tanks.

If the sauce formulation involves additional particulates—*e.g.,* diced mushrooms, raisins, or cooked meat—it is often desirable to precook the particulates and then blend them into sauce that has been already cooked and cooled. Although the particulates can be added prior to the cooking process, cooking them in sauce is usually avoided because of the adverse effects of heating on their texture.

ASSEMBLY AND FREEZING

Packages. Meal components are commonly assembled on trays made of aluminum foil, paperboard, plastic, or ceramic (see Figure 34). Special areas are stamped into the trays to create spaces for individual meal components. This type of package can be conveniently used directly by the consumer for reheating and then serving the food. In the case of boil-in-bag meals, the bag is made of laminated film. After a foodstuff is placed inside the bag, the air inside is evacuated, and the bag with its contents is frozen. The consumer simply places the bag with its contents in boiling water to prepare the meal.

Assembly. In order to assemble the prepared meal, adequate amounts of each meal component must be available. Often, meat portions, vegetables, and pasta are taken to the processing areas in large trays. Sauces are conveyed to the depositing areas by pumps. Depositing machines are then used automatically to weigh and place the required amounts of a given component directly onto the tray or into the bag.

© Bilderberg/The Stock Market

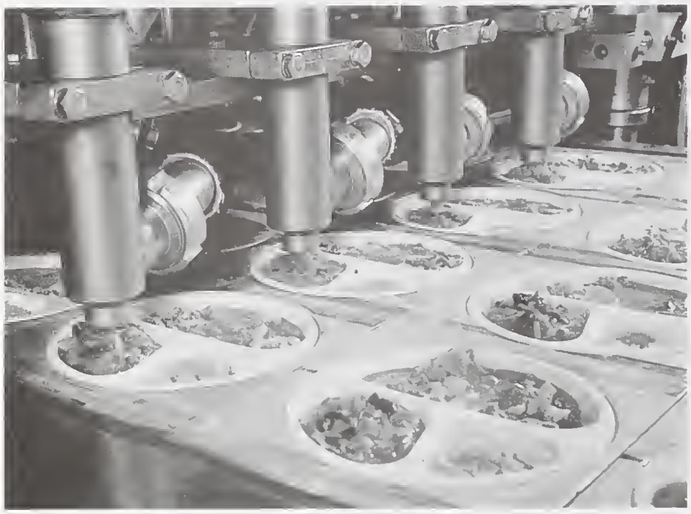

Figure 34: Depositing of prepared meals in trays prior to freezing.

Frozen vegetables are typically fed into a depositor through a feed chamber. The rotating bottom of the feed chamber usually contains several cavities that accept a designated amount of a food material. Under the depositing machines, the movement of the trays on the conveyor belts is sequenced. The cavities open directly over the meal tray above a designated slot. After the meat or vegetable is deposited on the tray, the sauce may be dispensed to coat the desired meal component.

Trays with meal components are inspected to assure that each item has been properly placed in the tray. Machines are used to detect any undesirable items such as metal or glass fragments. The trays are then conveyed directly to a freezer.

Freezing. Freezing of prepared and packaged meals is done rapidly to minimize changes in quality. Typically, once inside a freezer, foods are frozen to at least −40° C (−40° F) within 90 minutes.

Belt freezers

In one common type of freezer, the belt freezer, food trays or boil-in-bags are placed on a simple wire-mesh belt. The belt conveys the product into an air-blast room operated at −40° C. While a single belt arrangement is simple, a multitiered belt may be used to save floor space. In this case, a feed conveyor moves the product through several tiers of belts located inside the air-blast room.

Table 12: Processing Additives and Their Uses

function	typical chemical agent	typical product
Anticaking	sodium aluminosilicate	salt
Bleaching	benzoyl peroxide	flour
Chelating	ethylenediaminetetraacetic acid (EDTA)	dressings, mayonnaise, sauces, dried bananas
Clarifying	bentonite, proteins	fruit juices, wines
Conditioning	potassium bromate	flour
Emulsifying	lccithin	ice cream, mayonnaise, bakery products
Leavening	yeast, baking powder, baking soda	bakery products
Moisture control (humectants)	glyccrol	marshmallows, soft candies, chewing gum
pH control	citric acid, lactic acid	certain cheeses, confections, jams and jellies
Stabilizing and thickening	pectin, gelatin, carrageenan, gums (arabic, guar, locust bean)	dressings, frozen desserts, confections, pudding mixes, jams and jellies

A more compact arrangement employs a spiral belt. The spiral arrangement maximizes the belt surface area for a given floor space. A popular type of spiral freezer uses self-stacking belts. In the self-stacking arrangement, each tier rests on the vertical side flanges of the tier beneath. Several configurations of air flow are possible. Countercurrent vertical air flow, for instance, permits greater energy efficiencies. The air is channeled between the belts to minimize the time required for freezing. Faster rates of freezing minimize the dehydration of foods.

Plate freezers are commonly used for freezing brick-shaped packaged products. In plate freezers, refrigerant is allowed to circulate inside thin channels within the plates. The packaged products are firmly pressed between the plates. High rates of heat transfer can be obtained between the packaged product and the refrigerant plates.

After the freezing process, the frozen prepared foods are packaged in cartons. The cartons are labeled and stored in a frozen warehouse until needed for shipment to retail outlets. (R.P.Si.)

Food additives

Food additives, such as salt, spices, and sulfites, have been used since ancient times to preserve foods and make them more palatable. With the increased processing of foods in the 20th century, there came a need for both the greater use of and new types of food additives. Many modern products, such as low-calorie, snack, and ready-to-eat convenience foods, would not be possible without food additives.

Food additives and their metabolites are subjected to rigorous toxicological analysis prior to their approval for use in the industry. Feeding studies are carried out using animal species (*e.g.*, rats, mice, dogs) in order to determine the possible acute, short-term and long-term toxic effects of these chemicals. These studies monitor the effects of the compounds on the behaviour, growth, mortality, blood chemistry, organs, reproduction, offspring, and tumour development in the test animals over a 90-day to two-year period. The lowest level of additive producing no toxicological effects is termed the no-effect level (NOEL). The NOEL is generally divided by 100 to determine a maximum acceptable daily intake (ADI).

There are four general categories of food additives: nutritional additives, processing agents, preservatives, and sensory agents. These are not strict classifications, as many additives fall into more than one category.

NUTRITIONAL ADDITIVES

Nutritional additives are utilized for the purpose of restoring nutrients lost or degraded during production, fortifying or enriching certain foods in order to correct dietary deficiencies, or adding nutrients to food substitutes. The fortification of foods began in 1924 when iodine was added to table salt for the prevention of goitre. Vitamins are commonly added to many foods in order to enrich their nutritional value. For example, vitamins A and D are added to dairy and cereal products, several of the B vitamins are added to flour, cereals, baked goods, and pasta, and vitamin C is added to fruit beverages, cereals, dairy products, and confectioneries. Other nutritional additives include the essential fatty acid linoleic acid, minerals such as calcium and iron, and dietary fibre.

PROCESSING AGENTS

A number of agents are added to foods in order to aid in processing or to maintain the desired consistency of the product. Table 12 shows the functions performed by various processing agents employed in the food industry. Several of these agents are discussed in more detail below. For a discussion of leavening agents, see above *Bakery products: Ingredients: Leavening agents.*

Emulsifiers

Emulsifiers are used to maintain a uniform dispersion of one liquid in another, such as oil in water. The basic structure of an emulsifying agent includes a hydrophobic portion, usually a long-chain fatty acid, and a hydrophilic portion that may be either charged or uncharged. The hydrophobic portion of the emulsifier dissolves in the oil phase and the hydrophilic portion dissolves in the aqueous phase, forming a dispersion of small oil droplets. Emulsifiers thus form and stabilize oil-in-water emulsions (*e.g.,* mayonnaise), uniformly disperse oil-soluble flavour compounds throughout a product, prevent large ice crystal formation in frozen products (*e.g.,* ice cream), and improve the volume, uniformity, and fineness of baked products.

Stabilizers and thickeners have many functions in foods. Most stabilizing and thickening agents are polysaccharides, such as starches or gums, or proteins, such as gelatin. The primary function of these compounds is to act as thickening or gelling agents that increase the viscosity of the final product. These agents stabilize emulsions, either by adsorbing to the outer surface of oil droplets or by increasing the viscosity of the water phase. Thus, they prevent the coalescence of the oil droplets, promoting the separation of the oil phase from the aqueous phase (*i.e.,* creaming). The formation and stabilization of foam in a food product occurs by a similar mechanism, except that the oil phase is replaced by a gas phase. The compounds also act to inhibit the formation of ice or sugar crystals in foods and can be used to encapsulate flavour compounds.

Chelating, or sequestering, agents protect food products from many enzymatic reactions that promote deterioration during processing and storage. These agents bind to many of the minerals that are present in food (*e.g.,* calcium and magnesium) and are required as cofactors for the activity of certain enzymes.

PRESERVATIVES

Food preservatives are classified into two main groups: antioxidants and antimicrobials, as shown in Table 13. Antioxidants are compounds that delay or prevent the deterioration of foods by oxidative mechanisms. Antimicrobial agents inhibit the growth of spoilage and pathogenic microorganisms in food.

Antioxidants. The oxidation of food products involves the addition of an oxygen atom to or the removal of a hydrogen atom from the different chemical molecules found in food. Two principal types of oxidation that contribute to food deterioration are autoxidation of unsaturated fatty acids (*i.e.,* those containing one or more double bonds between the carbon atoms of the hydrocarbon chain) and enzyme-catalyzed oxidation.

The autoxidation of unsaturated fatty acids involves a reaction between the carbon-carbon double bonds and molecular oxygen (O_2). The products of autoxidation, called free radicals, are highly reactive, producing compounds that cause the off-flavours and off-odours characteristic of oxidative rancidity. Antioxidants that react with the free radicals (called free radical scavengers) can slow the rate of autoxidation. These antioxidants include the naturally occurring tocopherols (vitamin E derivatives) and the synthetic compounds butylated hydroxyanisole (BHA), butylated hydroxytoluene (BHT), and tertiary butylhydroquinone (TBHQ).

Prevention of browning

Specific enzymes may also carry out the oxidation of many food molecules. The products of these oxidation reactions may lead to quality changes in the food. For example, enzymes called phenolases catalyze the oxidation of certain molecules (*e.g.,* the amino acid tyrosine) when fruits and vegetables, such as apples, bananas, and potatoes, are cut or bruised. The product of these oxidation reactions, collectively known as enzymatic browning, is a dark pigment called melanin. Antioxidants that inhibit enzyme-catalyzed oxidation include agents that bind free oxygen (*i.e.,* reducing agents), such as ascorbic acid (vitamin C), and agents that inactivate the enzymes, such as citric acid and sulfites.

Antimicrobials. Antimicrobials are most often used with other preservation techniques, such as refrigeration, in order to inhibit the growth of spoilage and pathogenic microorganisms. Sodium chloride (NaCl), or common salt, is probably the oldest known antimicrobial agent. Organic acids, including acetic, benzoic, propionic, and sorbic acids, are used against microorganisms in products with a low pH. Nitratcs and nitrites are used to inhibit the bacterium *Clostridium botulinum* in cured meat products (*e.g.,* ham and bacon). Sulfur dioxide and sulfites are used to control the growth of spoilage microorganisms in dried fruits, fruit juices, and wines. Nisin and natamycin are preservatives produced by microorganisms. Nisin inhibits the growth of some bacteria while natamycin is active against molds and yeasts.

SENSORY AGENTS

Colorants. Colour is an extremely important sensory characteristic of foods; it directly influences the perception of both the flavour and quality of a product. The processing of food can cause degradation or loss of natural pigments in the raw materials. In addition, some formulated products, such as soft drinks, confections, ice cream, and snack foods, require the addition of colouring agents. Colorants are often necessary to produce a uniform product from raw materials that vary in colour intensity. Colorants used as food additives are classified as natural or synthetic. Natural colorants are derived from plant, animal, and mineral sources, while synthetic colorants are primarily petroleum-based chemical compounds.

Natural colorants. Most natural colorants are extracts derived from plant tissues. The use of these extracts in the food industry has certain problems associated with it, including the lack of consistent colour intensities, instability upon exposure to light and heat, variability of supply, reactivity with other food components, and addition of secondary flavours and odours. In addition, many are insoluble in water and therefore must be added with an emulsifier in order to achieve an cven distribution throughout the food product. Table 14 lists several natural colorants derived from plant extracts and used in various food products.

Table 13: Food Preservatives

chemical agent	mechanism of action
Antioxidants	
Ascorbic acid	oxygen scavenger
Butylated hydroxyanisole (BHA)	free radical scavenger
Butylated hydroxytoluene (BHT)	free radical scavenger
Citric acid	enzyme inhibitor/metal chelator
Sulfites	enzyme inhibitor/oxygen scavenger
Tertiary butylhydroquinone (TBHQ)	free radical scavenger
Tocopherols	free radical scavenger
Antimicrobials	
Acetic acid	disrupts cell membrane function (bacteria, yeasts, some molds)
Benzoic acid	disrupts cell membrane function/inhibits enzymes (molds, yeasts, some bacteria)
Natamycin	binds sterol groups in fungal cell membrane (molds, yeasts)
Nisin	disrupts cell membrane function (gram-positive bacteria, lactic acid-producing bacteria)
Nitrates, nitrites	inhibits enzymes/disrupts cell membrane function (bacteria, primarily *Clostridium botulinum*)
Propionic acid	disrupts cell membrane function (molds, some bacteria)
Sorbic acid	disrupts cell membrane function/inhibits enzymes/inhibits bacterial spore germination (yeasts, molds, some bacteria)
Sulfites and sulfur dioxide	inhibits enzymes/forms addition compounds (bacteria, yeasts, molds)

Numbering systems for colorants

Synthetic colorants. Synthetic colorants are water-soluble and are available commercially as powders, pastes, granules, or solutions. Special preparations called lakes are formulated by treating the colorants with aluminum hydroxide. They contain approximately 10 to 40 percent of the synthetic dye and are insoluble in water and organic solvents. Lakes are ideal for use in dry and oil-based products. The stability of synthetic colorants is affected by light, heat, pH, and reducing agents. A number of dyes have been chemically synthesized and approved for usage in various countries. These colorants are designated according to special numbering systems specific to individual countries. For example, the United States uses FD&C numbers (chemicals approved for use in foods, drugs, and cosmetics), and the European Union (EU) uses

Table 14: Natural Food Colorants

chemical class	colour	plant source	pigment	products
Anthocyanins	red	strawberry (*Fragaria* species)	pelargonidin 3-glucoside*	beverages, confections, preserves, fruit products
	blue	grape (*Vitis* species)	malvidin 3-glucoside*	beverages
Betacyanins	red	beetroot (*Beta vulgaris*)	betanin	dairy products, desserts, icings
Carotenoids**	yellow/orange	annatto (*Bixa orellana*)	bixin	dairy products, margarine
	yellow	saffron (*Crocus sativus*)	crocin	rice dishes, bakery products
	red/orange	paprika (*Capsicum annuum*)	capsanthin	soups, sauces
	orange	carrot (*Daucus carota*)	β-carotene	bakery products, confections
	red	mushroom (*Cantharellus cinnabarinus*)	canthaxanthin	sauces, soups, dressings
Phenolics	orange/yellow	turmeric (*Cuycuma longa*)	curcumin	dairy products, confections

*Plus other similar compounds. **Many carotenoids used as food colorants are chemically synthesized.

E numbers. Table 15 shows the most commonly used synthetic dyes.

All synthetic colorants have undergone extensive toxicological analysis. Brilliant Blue FCF, Indigo Carmine, Fast Green FCF, and Erythrosine are poorly absorbed and show little toxicity. Extremely high concentrations (greater than 10 percent) of Allura Red AC cause psychotoxicity, and Tartrazine induces hypersensitive reactions in some persons. Although none of the synthetic colorants listed above has been found to be carcinogenic in laboratory animals when administered orally, they are not universally approved in all countries. For example, while Allura Red AC is used extensively in the United States, it is banned from use in Canada.

Table 15: Synthetic Food Colorants

common name	designation		products
	United States	European Union	
Allura Red AC	FD&C Red No. 40	. . .	gelatin, puddings, dairy products, confections, beverages
Brilliant Blue FCF	FD&C Blue No. 1	E133	beverages, confections, icings, syrups, dairy products
Erythrosine	FD&C Red No. 3	E127	maraschino cherries
Fast Green FCF	FD&C Green No. 3	. . .	beverages, puddings, ice cream, sherbet, confections
Indigo Carmine	FD&C Blue No. 2	E132	confections, ice cream, bakery products
Sunset Yellow FCF	FD&C Yellow No. 6	E110	bakery products, ice cream, sauces, cereals, beverages
Tartrazine	FD&C Yellow No. 5	E102	beverages, cereals, bakery products, ice cream, sauces

Flavourings. The flavour of food results from the stimulation of the chemical senses of taste and smell by specific food molecules. Taste reception is carried out in specialized cells located in the taste buds. The four basic taste sensations—sweet, salty, bitter, and sour—are detected in separate regions of the tongue, mouth, and throat because the taste cells in each region are specific for certain flavour molecules (*e.g.*, sweeteners; see below).

In addition to the four basic tastes, the flavouring molecules in food stimulate specific olfactory (smell) cells in the nasal cavity. These cells can detect more than 10,000 different stimuli, thus fine-tuning the flavour sensation of a food.

A flavour additive is a single chemical or blend of chemicals of natural or synthetic origin that provides all or part of the flavour impact of a particular food. These chemicals are added in order to replace flavour lost in processing and to develop new products. Flavourings are the largest group of food additives, with more than 1,200 compounds available for commercial use. Natural flavourings are derived or extracted from plants, spices, herbs, animals, or microbial fermentations. Artificial flavourings are mixtures of synthetic compounds that may be chemically identical to natural flavourings. Artificial flavourings are often used in food products because of the high cost, lack of availability, or insufficient potency of natural flavourings.

Flavour enhancement

Flavour enhancers are compounds that are added to a food in order to supplement or enhance its own natural flavour. The concept of flavour enhancement originated in Asia, where cooks added seaweed to soup stocks in order to provide a richer flavour to certain foods. The flavour-enhancing component of seaweed was identified as the amino acid L-glutamate, and monosodium glutamate (MSG) became the first flavour enhancer to be used commercially. The rich flavour associated with L-glutamate was called *umami*. *Umami* is often considered the fifth basic taste because it is distinctly different from the other basic tastes (sweet, salty, sour, and bitter) and it is believed to activate a separate set of taste receptors.

Other compounds that are used as flavour enhancers include the 5′-ribonucleotides, inosine monophosphate (IMP), guanosine monophosphate (GMP), yeast extract, and hydrolyzed vegetable protein. Flavour enhancers may be used in soups, broths, sauces, gravies, flavouring and spice blends, canned and frozen vegetables, and meats.

Sweeteners. Sucrose or table sugar is the standard on which the relative sweetness of all other sweeteners is based. (For a discussion of sugar manufacture and refining, see above *Sugar*.) Because sucrose provides energy in the form of carbohydrates, it is considered a nutritive sweetener. Other nutritive sweeteners include glucose, fructose, corn syrup, high fructose corn syrup, and sugar alcohols (*e.g.*, sorbitol, mannitol, and xylitol).

Efforts to chemically synthesize sweeteners began in the late 1800s with the discovery of saccharin. Since then, a number of synthetic compounds have been developed that provide few or no calories or nutrients in the diet and are termed nonnutritive sweeteners. These sweeteners have significantly greater sweetening power than sucrose, and therefore a relatively low concentration may be used in food products. In addition to saccharin, the most commonly used nonnutritive sweeteners are cyclamates, aspartame, and acesulfame K. A comparison of the properties of these sweeteners is shown in Table 16.

The sensation of sweetness is transmitted through specific protein molecules, called receptors, located on the surface of specialized taste cells. All sweeteners function by binding to these receptors on the outside of the cells. The increased sweetness of the nonnutritive sweeteners relative to sucrose may be due to either tighter or longer binding of these synthetic compounds to the receptors.

Nonnutritive sweeteners are primarily used for the production of low-calorie products including baked goods, confectioneries, dairy products, desserts, preserves, soft

Table 16: Nonnutritive Sweeteners

chemical compound	relative sweetness (sucrose = 1)	temperature and pH stability	aftertaste
Acesulfame K	130–200	yes	bitter
Aspartame	150–200	no*	none
Cyclamates	30–80	yes	bitter, salty
Saccharin	200–700	yes	bitter, metallic

*An encapsulated preparation of aspartame has been developed for use in bakery products.

drinks, and tabletop sweeteners. They are also used as a carbohydrate replacement for persons with diabetes and in chewing gum and candies to prevent dental caries (*i.e.*, tooth decay). Unlike nutritive sweeteners, nonnutritive sweeteners do not provide viscosity or texture to products, so that bulking agents such as polydextrose are often required for manufacture.

Evaluating toxic effects of sweeteners

Toxicological analysis of the nonnutritive sweeteners has produced variable results. High concentrations of saccharin and cyclamates in the diets of rats have been shown to induce the development of bladder tumours in the animals. Because of these results, the use of cyclamates has been banned in several countries, including the United States, and the use of saccharin must include a qualifying statement regarding its potential health risks. However, no evidence of human bladder cancer has been reported with the consumption of these sweeteners. Both aspartame and acesulfame K are relatively safe, with no evidence of carcinogenic potential in animal studies. (P.M.D.)

BIBLIOGRAPHY

General works. R. MACRAE, R.K. ROBINSON, and M.J. SADLER (eds.), *Encyclopaedia of Food Science, Food Technology, and Nutrition,* 8 vol. (1993); and Y.H. HUI (ed.), *Encyclopedia of Food Science and Technology,* 4 vol. (1992), cover all aspects of the science of food. P. FELLOWS, *Food Processing Technology: Principles and Practices* (1988), is an introductory text. NORMAN N. POTTER, *Food Science,* 5th ed. (1995), treats the processing operations used for numerous food commodities. R. PAUL SINGH and FERNANDA A.R. OLIVEIRA (eds.), *Minimal Processing of Foods and Process Optimization* (1994), describes emerging technologies in this area.

R. PAUL SINGH and DENNIS R. HELDMAN, *Introduction to Food Engineering,* 2nd ed. (1993), provides introductory mathematical procedures useful in designing and analyzing food-processing operations. ROMEO T. TOLEDO, *Fundamentals of Food Process Engineering,* 2nd ed. (1991), an introductory text, contains mathematical analyses of a variety of food-processing operations. DENNIS R. HELDMAN and R. PAUL SINGH, *Food Process Engineering,* 2nd ed. (1981), an advanced text, quantitatively analyzes several unit operations commonly used in the food industry.

Food preservation and storage. MARCUS KAREL, OWEN R. FENNEMA, and DARYL B. LUND, *Physical Principles of Food Preservation* (1975), contains a quantitative description of commonly used food-processing operations. S.D. HOLDSWORTH, *Aseptic Processing and Packaging of Food Products* (1992), is a comprehensive text. JAMES M. JAY, *Modern Food Microbiology,* 4th ed. (1992), offers an introduction to the role of microorganisms in the food supply, covering the history of food microbiology as a science, the factors that affect microbial growth, the incidence and types of microorganisms found in foods, food preservation, and the part microorganisms play in food spoilage and related diseases. P.R. HAYES, *Food Microbiology and Hygiene,* 2nd ed. (1992), details the fundamentals of food microbiology and the hygienic aspects of the design and operation of food-processing equipment.

C.M.D. MAN and A.A. JONES (eds.), *Shelf Life Evaluation of Foods* (1994), examines various food commodities in terms of their shelf life and discusses methods used to study the shelf life of foods. THEODORE P. LABUZA, *The Shelf-Life Dating of Foods* (1982), a reference book, contains information on the shelf life of numerous food products and provides approaches to mathematical prediction of the shelf life of foods. (R.P.Si.)

Cereals and other starch products. The composition, processing, and uses of cereals and other starch products are discussed in GIUSEPPE FABRIANI and CLAUDIA LINTAS (eds.), *Durum Wheat: Chemistry and Technology* (1988); Y. POMERANZ (ed.), *Wheat: Chemistry and Technology,* 3rd ed., 2 vol. (1988), and *Wheat Is Unique: Structure, Composition, Processing, End-Use Properties, and Products* (1989); Y. POMERANZ, *Industrial Uses of Cereals* (1973), and *Modern Cereal Science and Technology* (1987); *Advances in Cereal Science and Technology* (biennial); STANLEY A. WATSON and PAUL E. RAMSTAD (eds.), *Corn: Chemistry and Technology* (1987); BIENVENIDO O. JULIANO (ed.), *Rice: Chemistry and Technology,* 2nd ed. (1985); RUTH H. MATTHEWS (ed.), *Legumes: Chemistry, Technology, and Human Nutrition* (1989); ALLAN K. SMITH and SIDNEY J. CIRCLE (eds.), *Soybeans: Chemistry and Technology,* vol. 1, *Proteins,* rev. ed. (1978); HARRY E. SNYDER and T.W. KWON, *Soybean Utilization* (1987); and SOY PROTEIN COUNCIL, *Soy Protein Products: Characteristics, Nutritional Aspects, and Utilization* (1987).

Some starch products are treated in R. GORDON BOOTH (ed.), *Snack Food* (1990), discussing the snack food industry in the United States and Great Britain; and ROBERT B. FAST and ELWOOD F. CALDWELL (eds.), *Breakfast Cereals, and How They Are Made* (1990). (Ed.)

Edible fats and oils. D.K. SALUNKHE *et al.*, *World Oilseeds: Chemistry, Technology, and Utilization* (1992), provides an overview. Nuts are treated in JASPER GUY WOODROOF, *Tree Nuts: Production, Processing, Products,* 2nd ed. (1979); and FREDERIC ROSENGARTEN, JR., *The Book of Edible Nuts* (1984). (Ed.)

Bakery products. Various aspects of the topic are treated in books by SAMUEL A. MATZ: *Ingredients for Bakers* (1987), containing descriptions of the raw materials used by bakers, *Formulas and Processes for Bakers* (1987), presenting guidelines used in formulating doughs and batters, examples of many typical formulas, explanations of changes occurring in mixing, fermenting, shaping, and cooking, and the effects that processing variables may have on the quality of the finished product, *Equipment for Bakers* (1988), discussing the different machines used in retail and wholesale bakeries, including the specifications and functions of individual models, *Bakery Technology: Packaging, Nutrition, Product Development, QA* (1989), and *Cookie and Cracker Technology,* 3rd ed. (1992). Additional works include E.J. PYLER, *Baking Science & Technology,* 3rd ed., 2 vol. (1988); WILLIAM J. SULTAN, *Practical Baking,* 5th ed. (1990), a survey of the art and craft of professional baking; and D.J.R. MANLEY, *Technology of Biscuits, Crackers, and Cookies,* 2nd ed. (1991).

A more fundamental approach to some of the problems in baking science can be found in HAMED A. FARIDI and JON M. FAUBION (eds.), *Dough Rheology and Baked Product Texture* (1990). (S.A.M.)

Fruits. A.C. HULME (ed.), *The Biochemistry of Fruits and Their Products,* 2 vol. (1970–71), provides a detailed discussion, as does the work by Jen cited in the paragraph below. DONALD L. DOWNING, *Processed Apple Products* (1989), the definitive text on this particular topic, details all significant commercial processes, including equipment and procedures. R.M. SMOCK and A.M. NEUBERT, *Apples and Apple Products* (1950), offers an extraordinary collection of bibliographic references. (M.R.McL.)

Vegetables. JOSEPH J. JEN (ed.), *Quality Factors of Fruits and Vegetables: Chemistry and Technology* (1989), describes the four major factors—colour, flavour, texture, and nutritive value—that determine food quality and discusses new technology used in food processing. Other works on vegetable processing include BOR SHIUN LUH and JASPER GUY WOODROOF, *Commercial Vegetable Processing,* 2nd ed. (1988), the most complete treatment of the subject, with chapters on quality control, nutrition labeling, and computer usage in food processing; WILLIAM F. TALBURT and ORA SMITH (eds.), *Potato Processing,* 4th ed. (1987), a comprehensive text; and MAS YAMAGUCHI, *World Vegetables: Principles, Production, and Nutritive Values* (1983), presenting a global view of vegetable production. (Jo.J.J.)

Fish. GEORGE M. PIGOTT and BARBEE W. TUCKER, *Seafood: The Effects of Technology on Nutrition* (1990), aimed at a general audience, discusses the effects that handling and processing methods may have on the nutritional value of seafood. E. GRAHAM BLIGH (ed.), *Seafood Science and Technology* (1992), written for the professional, covers the basic principles of seafood chemistry, microbiology, and technology. Two articles by GEORGE M. PIGOTT, "Flavors and Acceptance of Formulated Seafood Products," *Food Reviews International,* 6(4):661–680 (1990), and "Who Is the 21st Century Consumer?" *INFOFISH International,* 1:12–20 (January–February 1994), are also useful. (G.M.P.)

Meat. Detailed overviews include HAROLD B. HEDRICK *et al.*, *Principles of Meat Science,* 3rd ed. (1994); JOHN R. ROMANS *et al.*, *The Meat We Eat,* 13th ed. (1994); and H.R. CROSS and A.J. OVERBY (eds.), *Meat Science, Milk Science, and Technology* (1988), which includes comparisons of methods of meat production and processing in various countries.

PETER J. BECHTEL (ed.), *Muscle As Food* (1986); and A.J. BAILEY and N.D. LIGHT, *Connective Tissue in Meat and Meat Products* (1989), discuss physical and biochemical aspects.

Processed-meat science and technology is treated in HERBERT W. OCKERMAN, *Sausage and Processed Meat Formulations* (1989); and A.M. PEARSON and F.W. TAUBER, *Processed Meats*, 2nd ed. (1984). HERBERT W. OCKERMAN and C.L. HANSEN, *Animal By-Product Processing* (1988), covers the production of edible meat products, hides, glue, bone and meat meals, pharmaceutical products, sausage casings, pet foods, and animal waste products. (H.R.C.)

Poultry. ROBERT E. MORENG and JOHN S. AVENS, *Poultry Science and Production* (1985, reissued 1991), is a well-illustrated overview of all aspects of the poultry industry and avian biology. WILLIAM J. STADELMAN *et al., Egg and Poultry-Meat Processing* (1988), deals with nutritional aspects and contains a full listing of USDA-approved poultry products. (J.M.Re.)

Eggs. WILLIAM J. STADELMAN and OWEN J. COTTERILL, *Egg Science and Technology*, 3rd ed. (1986, reissued 1990), provides in-depth information on egg chemistry, composition, specialized processes, functional properties, quality measurements, and new uses for eggs and egg products. G.W. FRONING, "New Product Innovations from Eggs," chapter 4 in B.J.F. HUDSON (ed.), *New and Developing Sources of Food Proteins* (1994), pp. 71–94, provides information on new processing technologies and new egg products. The work by Stadelman *et al.* cited in the previous paragraph is also useful. (G.W.F.)

Dairy products. R. EARLY (ed.), *The Technology of Dairy Products* (1992); and ALAN H. VARNAM and JANE P. SUTHERLAND, *Milk and Milk Products: Technology, Chemistry, and Microbiology* (1994), treat the general field of dairy technology and provide a broad view of processing considerations for dairy products. Y.U. HUI (ed.), *Dairy Science and Technology Handbook*, 3 vol. (1993), brings together needed information on the principles and properties of dairy ingredients and on manufacturing technologies, applications, and engineering.

Works specifically covering the chemistry and microbiological disciplines are NOBLE P. WONG (ed.), *Fundamentals of Dairy Chemistry*, 3rd ed. (1988); and R.K. ROBINSON (ed.), *Dairy Microbiology*, 2nd ed., 2 vol. (1990). Testing and analytical procedures are covered by *Standard Methods for the Examination of Dairy Products*, 16th ed. (1993); and *Official Methods of Analysis of the Association of Official Analytical Chemists* (quinquennial). F.W. BODYFELT, J. TOBIAS, and G.M. TROUT, *The Sensory Evaluation of Dairy Products* (1988), is the best reference for organoleptic properties.

W.S. ARBUCKLE, *Ice Cream*, 4th ed. (1986), a classic text, chronicles the development of the ice cream industry, covering all aspects from manufacturing technology to techniques for dipping and serving. The most useful work for the cheese industry is FRANK KOSIKOWSKI, *Cheese and Fermented Milk Foods*, 2nd ed. (1977, reissued 1982), providing detailed explanations, descriptions, and procedures for making and enjoying cheese. P.F. FOX (ed.), *Cheese: Chemistry, Physics, and Microbiology*, 2 vol. (1987), contains more detailed scientific explanations on the cheese-making process. VINCENT L. ZEHREN and D.D. (DAVE) NUSBAUM, *Process Cheese* (1992), discusses technology. RICHARD K. ROBINSON (ed.), *A Colour Guide to Cheese and Fermented Milks* (1995); and BERNARD NANTET *et al., Cheeses of the World* (1993), are two illustrated popular texts. (D.K.B.)

Sugar.. JAMES C.P. CHEN and CHUNG-CHI CHOU, *Chen-Chou Cane Sugar Handbook: A Manual for Cane Sugar Manufacturers and Their Chemists*, 12th ed. (1993), contains detailed descriptions of raw and refined cane-sugar processes. R.A. MCGINNIS (ed.), *Beet-Sugar Technology*, 3rd ed. (1982), provides detailed and extensive descriptions of sugar beet production and beet sugar manufacture. MARGARET A. CLARKE and MARY AN GODSHALL (eds.), *Chemistry and Processing of Sugarbeet and Sugarcane* (1988), discusses recent and predicted developments in cane and beet sugar manufacture as well as the by-products of sugarcane and sugar beets. NEIL L. PENNINGTON and CHARLES W. BAKER (eds.), *Sugar: A User's Guide to Sucrose* (1990), details sugarcane and sugar beet properties and behaviour in food processing. (M.A.C.)

Cocoa products. The cocoa and chocolate industry from the growing of cocoa beans to the finished cocoa and chocolate products is covered in L. RUSSELL COOK, *Chocolate Production and Use*, 3rd ed., rev. by E.H. MEURSING (1982). JOHN SIMMONS (ed.), *Cocoa Production: Economic and Botanical Perspectives* (1976), a basic source, includes a worldwide survey of research. G.A.R. WOOD and R.A. LASS, *Cocoa*, 4th ed. (1985), discusses cocoa production in various countries. (L.R.C./Ed.)

Confectionery and candy. BERNARD W. MINIFIE, *Chocolate, Cocoa, and Confectionery: Science and Technology*, 3rd ed. (1989), deals with production methods, machinery, and formulations with scientific explanations. C. TREVOR WILLIAMS, *Chocolate and Confectionery*, 3rd ed. (1964), is a general survey of the industry with details of processes, machinery, and recipes in some sections. E. SKUSE, *Complete Confectioner*, 13th ed., rev. and edited by W.J. BUSH & CO. (1957), deals mainly with sugar confectionery. ERNEST J. CLYNE, *A Course in Confectionery*, 2 vol. in 1 (1955), also deals mainly with sugar confectionery. Journals such as *Confectionery Production* (monthly); and *The Manufacturing Confectioner* (monthly), contain useful current information. (H.B.K./B.W.M.)

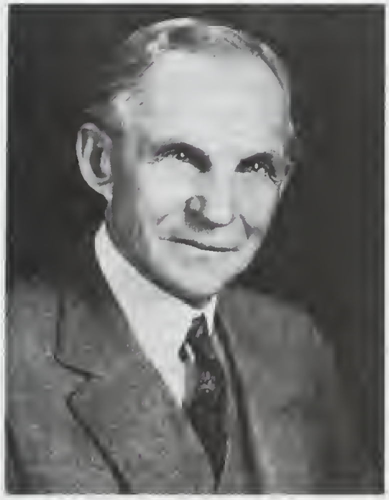
Frozen prepared foods. C.P. MALLETT (ed.), *Frozen Food Technology* (1993), is a reference book. INTERNATIONAL INSTITUTE OF REFRIGERATION, *Recommendations for the Processing and Handling of Frozen Foods*, 3rd ed. (1986), in English and French, discusses various industrial methods used in food freezing and provides recommendations on optimal conditions for freezing and for frozen storage of various food commodities. MOGENS JUL, *The Quality of Frozen Foods* (1984), describes changes in the quality of foods during frozen storage and includes calculations to determine the shelf life of frozen foods. (R.P.Si.)

Food additives. A. LARRY BRANEN, P. MICHAEL DAVIDSON, and SEPPO SALMINEN (eds.), *Food Additives* (1990), treats all aspects of the subject. THOMAS E. FURIA (ed.), *CRC Handbook of Food Additives*, 2nd ed., 2 vol. (1972, reissued 1980), contains a classification and description of the compounds used as food additives, as well as commercial forms, functions, applications, stability, and regulatory status of individual agents. JOSEPH A. MAGA and ANTHONY T. TU (eds.), *Food Additive Toxicology* (1995), discusses toxicological aspects. TIM SMITH (ed.), *Food Additive User's Handbook* (1991), provides tables containing data on the functions, characteristics, processing stability, and applications of specific food additives. (P.M.D.)

Henry Ford

Henry Ford spent most of his life making headlines, good, bad, but never indifferent. Celebrated as both a technological genius and a folk hero, Ford was the creative force behind an industry of unprecedented size and wealth that in only a few decades permanently changed the economic and social character of the United States. When young Ford left his father's farm in 1879 for Detroit, only two out of eight Americans lived in cities; when he died at age 83, the proportion was five out of eight. Once Ford realized the tremendous part he and his Model T automobile had played in bringing about this change, he wanted nothing more than to reverse it, or at least to recapture the rural values of his boyhood. Henry Ford, then, is an apt symbol of the transition from an agricultural to an industrial America.

By courtesy of the Ford Archives, Henry Ford Museum, Dearborn, Michigan



Ford, 1933.

Early life. Henry Ford was one of eight children of William and Mary Ford. He was born on the family farm near Dearborn, Michigan, then a town eight miles west of Detroit, on July 30, 1863. Abraham Lincoln was president of the 24 states of the Union, and Jefferson Davis was president of the 11 states of the Confederacy. Ford attended a one-room school for eight years when he was not helping his father with the harvest. At age 16 he walked to Detroit to find work in its machine shops. After three years, during which he came in contact with the internal-combustion engine for the first time, he returned to the farm, where he worked part-time for the Westinghouse Engine Company and in spare moments tinkered in a little machine shop he set up. Eventually he built a small "farm locomotive," a tractor that used an old mowing machine for its chassis and a homemade steam engine for power.

Ford moved back to Detroit nine years later as a married man. His wife, Clara Bryant, had grown up on a farm not far from Ford's. They were married in 1888, and on November 6, 1893, she gave birth to their only child, Edsel Bryant. A month later Ford was made chief engineer at the main Detroit Edison Company plant with responsibility for maintaining electric service in the city 24 hours a day. Because he was on call at all times, he had no regular hours and could experiment to his heart's content. He had determined several years before to build a gasoline-powered vehicle, and his first working gasoline engine was completed at the end of 1893. By 1896 he had completed his first horseless carriage, the "Quadricycle," so called because the chassis of the four-horsepower vehicle was a buggy frame mounted on four bicycle wheels. Unlike many other automotive inventors, including Charles Edgar and J. Frank Duryea, Elwood Haynes, Hiram Percy Maxim, and his Detroit acquaintance Charles Brady King, all of whom had built self-powered vehicles before Ford but who held onto their creations, Ford sold his to finance work on a second vehicle, and a third, and so on.

During the next seven years he had various backers, some of whom, in 1899, formed the Detroit Automobile Company (later the Henry Ford Company), but all eventually abandoned him in exasperation because they wanted a passenger car to put on the market while Ford insisted always on improving whatever model he was working on, saying that it was not ready yet for customers. He built several racing cars during these years, including the "999" racer driven by Barney Oldfield, and set several new speed records. In 1902 he left the Henry Ford Company, which subsequently reorganized as the Cadillac Motor Car Company. Finally, in 1903, Ford was ready to market an automobile. The Ford Motor Company was incorporated, this time with a mere $28,000 in cash put up by ordinary citizens, for Ford had, in his previous dealings with backers, antagonized the wealthiest men in Detroit.

Ford Motor Company

The company was a success from the beginning, but just five weeks after its incorporation the Association of Licensed Automobile Manufacturers threatened to put it out of business because Ford was not a licensed manufacturer. He had been denied a license by this group, which aimed at reserving for its members the profits of what was fast becoming a major industry. The basis of their power was control of a patent granted in 1895 to George Baldwin Selden, a patent lawyer of Rochester, New York. The association claimed that the patent applied to all gasoline-powered automobiles. Along with many rural Midwesterners of his generation, Ford hated industrial combinations and Eastern financial power. Moreover, Ford thought the Selden patent preposterous. All invention was a matter of evolution, he said, yet Selden claimed genesis. He was glad to fight, even though the fight pitted the puny Ford Motor Company against an industry worth millions of dollars. The gathering of evidence and actual court hearings took six years. Ford lost the original case in 1909; he appealed and won in 1911. His victory had wide implications for the industry, and the fight made Ford a popular hero.

"I will build a motor car for the great multitude," Ford proclaimed in announcing the birth of the Model T in October 1908. In the 19 years of the Model T's existence, he sold 15,500,000 of the cars in the United States, almost 1,000,000 more in Canada, and 250,000 in Great Britain, a production total amounting to half the auto output of the world. The motor age arrived owing mostly to Ford's vision of the car as the ordinary man's utility rather than as the rich man's luxury. Once only the rich had travelled freely around the country; now millions could go wherever they pleased. The Model T was the chief instrument of one of the greatest and most rapid changes in the lives of the common people in history, and it effected this change in less than two decades. Farmers were no longer isolated on remote farms. The horse disappeared so rapidly that the transfer of acreage from hay to other crops caused an agricultural revolution. The automobile became the main prop of the American economy and a stimulant to urbanization—cities spread outward, creating suburbs and housing developments—and to the building of the finest highway system in the world.

The remarkable birth rate of Model T's was made possible by the most advanced production technology yet conceived. After much experimentation by Ford and his engineers, the system that had evolved by 1913–14 in Ford's new plant in Highland Park, Michigan, was able to deliver parts, subassemblies, and assemblies (themselves built on subsidiary assembly lines) with precise timing to a constantly moving main assembly line, where a complete chassis was turned out every 93 minutes, an enormous improvement over the 728 minutes formerly required. The minute subdivision of labour and the coordination of a multitude of operations produced huge gains in productivity.

In 1914 the Ford Motor Company announced that it would henceforth pay eligible workers a minimum wage of $5 a day (compared to an average of $2.34 for the industry) and would reduce the work day from nine hours to eight, thereby converting the factory to a three-shift day. Overnight Ford became a worldwide celebrity. People either praised him as a great humanitarian or excoriated him as a mad socialist. Ford said humanitarianism had nothing to do with it. Previously profit had been based on paying wages as low as workers would take and pricing cars as high as the traffic would bear. Ford, on the other hand, stressed low pricing (the Model T cost $950 in 1908 and $290 in 1927) in order to capture the widest possible market and then met the price by volume and efficiency. Ford's success in making the automobile a basic necessity turned out to be but a prelude to a more widespread revolution. The development of mass-production techniques, which enabled the company eventually to turn out a Model T every 24 seconds; the frequent reductions in the price of the car made possible by economies of scale; and the payment of a living wage that raised workers above subsistence and made them potential customers for, among other things, automobiles—these innovations changed the very structure of society.

During its first five years the Ford Motor Company produced eight different models, and by 1908 its output was 100 cars a day. The stockholders were ecstatic; Ford was dissatisfied and looked toward turning out 1,000 a day. The stockholders seriously considered court action to stop him from using profits to expand. In 1909 Ford, who owned 58 percent of the stock, announced that he was only going to make one car in the future, the Model T. The only thing the minority stockholders could do to protect their dividends from his all-consuming imagination was to take him to court, which Horace and John Dodge did in 1916.

The Dodge brothers, who formerly had supplied chassis to Ford but were now manufacturing their own car while still holding Ford stock, sued Ford for what they claimed was his reckless expansion and for reducing prices of the company's product, thereby diverting money from stockholders' dividends. The court hearings gave Ford a chance to expound his ideas about business. In December 1917 the court ruled in favour of the Dodges; Ford, as in the Selden case, appealed, but this time he lost. In 1919 the court said that, while Ford's sentiments about his employees and customers were nice, a business is for the profit of its stockholders. Ford, irate that a court and a few shareholders, whom he likened to parasites, could interfere with the management of his company, determined to buy out all the shareholders. He had resigned as president in December 1918 in favour of his son, Edsel, and in March 1919 he announced a plan to organize a new company to build cars cheaper than the Model T. When asked what would become of the Ford Motor Company, he said, "Why I don't know exactly what will become of that; the portion of it that does not belong to me cannot be sold to me, that I know." The Dodges, somewhat inconsistently, having just taken him to court for mismanagement, vowed that he would not be allowed to leave. Ford said that if he was not master of his own company, he would start another. The ruse worked; by July 1919 Ford had bought out all seven minority stockholders. (The seven had little to complain about: in addition to being paid nearly $106,000,000 for their stock, they received a court-ordered dividend of $19,275,385 plus $1,536,749 in interest.) Ford Motor Company was reorganized under a Delaware charter in 1920 with all shares held by Ford and other family members. Never had one man controlled so completely a business enterprise so gigantic.

The winning Ford Model T entry on the road during the 1909 transcontinental race, New York City to Seattle, Washington.

By courtesy of Ford Motor Company Archives

The planning of a huge new plant at River Rouge, Michigan, had been one of the specific causes of the Dodge suit. What Ford dreamed of was not merely increased capacity but complete self-sufficiency. World War I, with its shortages and price increases, demonstrated for him the need to control raw materials; slow-moving suppliers convinced him that he should make his own parts. Wheels, tires, upholstery, and various accessories were purchased from other companies around Detroit. As Ford production increased, these smaller operations had to speed their output; most of them had to install their own assembly lines. It became impossible to coordinate production and shipment so that each product would arrive at the right place and at the right time. At first he tried accumulating large inventories to prevent delays or stoppages of the assembly line, but he soon realized that stockpiling wasted capital. Instead he took up the idea of extending movement to inventories as well as to production. He perceived that his costs in manufacturing began the moment the raw material was separated from the earth and continued until the finished product was delivered to the consumer. The plant he built in River Rouge embodied his idea of an integrated operation encompassing production, assembly, and transportation. To complete the vertical integration of his empire, he purchased a railroad, acquired control of 16 coal mines and about 700,000 (285,000 hectares) acres of timberland, built a sawmill, acquired a fleet of Great Lakes freighters to bring ore from his Lake Superior mines, and even bought a glassworks.

Vertical integration at River Rouge

The move from Highland Park to the completed River Rouge plant was accomplished in 1927. At 8 o'clock any morning, just enough ore for the day would arrive on a Ford freighter from Ford mines in Michigan and Minnesota and would be transferred by conveyor to the blast furnaces and transformed into steel with heat supplied by coal from Ford mines in Kentucky. It would continue on through the foundry molds and stamping mills and exactly 28 hours after arrival as ore would emerge as a finished automobile. Similar systems handled lumber for floorboards, rubber for tires, and so on. At the height of its success the company's holdings stretched from the iron mines of northern Michigan to the jungles of Brazil, and it operated in 33 countries around the globe. Most remarkably, not one cent had been borrowed to pay for any of it. It was all built out of profits from the Model T.

Later years. The unprecedented scale of that success, together with Ford's personal success in gaining absolute control of the firm and driving out subordinates with contrary opinions, set the stage for decline. Trusting in what he believed was an unerring instinct for the market, Ford refused to follow other automobile manufacturers in offering such innovative features as conventional gearshifts (he held out for his own planetary gear transmission), hydraulic brakes (rather than mechanical ones), six- and

The Model A and the Ford V-8

eight-cylinder engines (the Model T had a four), and choice of colour (from 1914 every Model T was painted black). When he was finally convinced that the marketplace had changed and was demanding more than a purely utilitarian vehicle, he shut down his plants for five months to retool. In December 1927 he introduced the Model A. The new model enjoyed solid but not spectacular success. Ford's stubbornness had cost him his leadership position in the industry; the Model A was outsold by General Motors' Chevrolet and Chrysler's Plymouth and was discontinued in 1931. Despite the introduction of the Ford V-8 in 1932, by 1936 Ford Motor Company was third in sales in the industry.

A similar pattern of authoritarian control and stubbornness marked Ford's attitude toward his workers. The $5 day that brought him so much attention in 1914 carried with it, for workers, the price of often overbearing paternalism. It was, moreover, no guarantee for the future; in 1929 Ford instituted a $7 day, but in 1932, as part of the fiscal stringency imposed by falling sales and the Great Depression, that was cut to $4, below prevailing industry wages. Ford freely employed company police, labour spies, and violence in a protracted effort to prevent unionization and continued to do so even after General Motors and Chrysler had come to terms with the United Automobile Workers. When the UAW finally succeeded in organizing Ford workers in 1941, he considered shutting down before he was persuaded to sign a union contract.

During the 1920s, under Edsel Ford's nominal presidency, the company diversified by acquiring the Lincoln Motor Car Company, in 1922, and venturing into aviation. At Edsel's death in 1943 Henry Ford rcsumed the presidency and, in spite of age and infirmity, held it until 1945, when he retired in favour of his grandson, Henry Ford II.

Henry Ford was a complex personality. Away from the shop floor he exhibited a variety of enthusiasms and prejudices and, from time to time, startling ignorancc. His dictum that "history is more or less bunk" was widely publicized, as was his deficiency in that field revealed during cross-examination in his million-dollar libel suit against the *Chicago Tribune* in 1919; a *Tribune* editorial had called him an "ignorant idealist" because of his opposition to U.S. involvement in World War I, and while the jury found for Ford it awarded him only six ccnts. One of Ford's most publicized acts was his chartering of an ocean liner to conduct himself and a party of pacifists to Europe in November 1915 in an attempt to cnd thc war by means of "continuous mediation." The so-called Peace Ship episode was widcly ridiculed. In 1918, with the support of Pres. Woodrow Wilson, Ford ran for a U.S. Senate seat from Michigan. He was narrowly defeated after a campaign of personal attacks by his opponent.

In 1918 Ford bought a newspaper, *The Dearborn Independent*, and in it published a series of scurrilous attacks on the "International Jew," a mythical figure he blamed for financing war; in 1927 he formally retracted his attacks and sold the paper. He gave old-fashioned dances at which capitalists, European royalty, and company executives were introduced to the polka, the Sir Roger de Coverley, the mazurka, the Virginia reel, and the quadrille; he established small village factories; he built one-room schools in which vocational training was emphasized; he experimented with soybeans for food and durable goods; he sponsored a weekly radio hour on which quaint essays were read to "plain folks"; he constructed Greenfield Village, a restored rural town; and he built what later was named the Henry Ford Museum and filled it with American artifacts and antiques from the era of his youth when American society was almost wholly agrarian. In short, he was a man who baffled even those who had the opportunity to observe him close at hand, all except James Couzens, Ford's business manager from the founding of the company until his resignation in 1915, who always said, "You cannot analyze genius and Ford is a genius."

Ford died at home on April 7, 1947, exactly 100 years after his father had left Ireland for Michigan. His holdings in Ford stock went to the Ford Foundation, which had been set up in 1936 as a means of retaining family control of the firm and which subsequently became the richest private foundation in the world.

BIBLIOGRAPHY. Ford was the nominal coauthor of three books in collaboration with SAMUEL CROWTHER: *My Life and Work* (1922, reprinted 1987), *Today and Tomorrow* (1926, reprinted 1988), and *Moving Forward* (1930). Especially recommended studies of his life and activities are ALLAN NEVINS and FRANK ERNEST HILL, *Ford: The Times, the Man, the Company* (1954), *Ford: Expansion and Challenge, 1915–1933* (1957), and *Ford: Decline and Rebirth, 1933–1962* (1963); CAROL W. GELDERMAN, *Henry Ford: The Wayward Capitalist* (1981), a full-length biography and a study of his company's development; ROBERT LACEY, *Ford: The Men and the Machine* (1986), beginning with a biography of Ford and progressing to a history of the following generations of the Ford family; ROGER BURLINGAME, *Henry Ford* (1955, reissued 1969), a short profile; WILLIAM GREENLEAF, *Monopoly on Wheels* (1961), a discussion of the Selden patent case; LOUIS P. LOCHNER, *Henry Ford: America's Don Quixote* (1925), about the Peace Ship voyage to Europe; BARBARA S. KRAFT, *The Peace Ship* (1978), a more recent treatment; and REYNOLD M. WIK, *Henry Ford and Grass-Roots America* (1972), a catalog of fan letters received by Ford. DAVID L. LEWIS, *The Public Image of Henry Ford* (1976), examines the media's portrayal of Ford and his company as well as the company's efforts to influence that portrayal. (C.W.G.)

Forestry and Wood Production

Forestry is the science of developing and managing woodlands, along with the wastelands and waters and other resources associated with them, for the benefit of humankind. The meaning of the term "benefit" in this definition may be either narrowly or broadly understood. A narrow understanding of the term might be as the maximization of the production of immediately marketable timber and the minimization of associated production costs; a broader understanding might look to some optimal sustained rate of yield consistent with the preservation of such other long-term goods as wildlife and recreational opportunities. The evolution of the practice of forestry has to a large degree paralleled that of natural-resource conservation generally. As a consequence, while the chief object of forestry is usually the raising and harvesting of successive crops of timber, professional foresters have increasingly become involved in activities related to the conservation of soil, water, and wildlife resources and to recreation.

This article deals with two distinct but closely related topics. First, it traces the history of forestry from its origin in ancient practices to its development as a scientific profession in the modern world, and it discusses the kinds and distribution of forests as well as the principal techniques and methods of modern forest management in some detail. Second, the nature of the principal forest product—wood—is discussed in the context of the ways in which it is typically processed and utilized.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* sections 355, 724, and 731, and the *Index.*

This article is divided into the following sections:

Forestry

HISTORY

The ancient world. It is believed that *Homo erectus* used wood for fire at least 750,000 years ago. The oldest evidence of the use of wood for construction, found at the Kalambo Falls site in Tanzania, dates from some 60,000 years ago. Early organized communities were located along waterways that flowed through the arid regions of India, Pakistan, Egypt, and Mesopotamia, where scattered trees along riverbanks were used much as they are today—for fuel, construction, and handles for tools. Writers of the Old Testament make frequent reference to the use of wood. Pictures in Egyptian tombs show the use of the wooden plow and other wooden tools to prepare the land for sowing. Carpenters and shipwrights fabricated wooden boats as early as 2700 BC. Theophrastus, Varro, Pliny, Cato, and Virgil wrote extensively on the subject of trees, their classification, manner of growth, and the environmental characteristics that affect them.

The Romans took a keen interest in trees and imported tree seedlings throughout the Mediterranean region and Germany, establishing groves comparable to those in Carthage, Lebanon, and elsewhere. The fall of the Roman Empire signaled an end to conservation works throughout the Mediterranean and a renewal of unregulated cutting, fire, and grazing of sheep and goats, which resulted in the destruction of the forests. This, in turn, caused serious soil loss, silting of streams and harbours, and the conversion of forest to a scrubby brush cover known as maquis.

Medieval Europe. In medieval Europe, forest laws were aimed initially at protecting game and defining rights and responsibilities. Hunting rights were vested in the feudal lord who owned the property and who had the sole right to cut trees and export timber. Peasants were permitted to gather fuel, timber, and litter for use on their own properties and to pasture defined numbers of animals. By 1165, however, land clearing for agriculture had gone so far that Germany forbade further forest removal. The systematic management of forests had its true beginnings, however, in the German states during the 16th century. Each forest property was divided into sections for timber harvesting and regeneration to ensure a sustainable yield of timber for the entire property. This working plan called for accurate maps and assessments of timber volume and expected growth rates.

The first forest nursery

Trees have been raised from seed or cuttings since biblical times, but the earliest record of a planned forest nursery is that of William Blair, cellarer to the Abbey of Coupar Angus in Scotland, who raised trees to grow in the Highland Forest of Ferter as early as 1460. After the dissolution of the monasteries, many newly rich landowners in Scotland and England found a profitable long-term investment in artificial plantations established on poor land. John Evelyn, a courtier in the reign of Charles II, published his classic textbook *Sylva* in 1664, exhorting them to do so, and today virtually all of Britain's 2,100,000 hectares (5,200,000 acres) of woodland consists of artificial plantations. Other countries had managed their natural forests better and had little need, until recently, to afforest bare land. The 20th century, however, has seen a tremendous expansion of artificial plantations in all the continents, planned to meet the ever-growing needs for wood and paper as essential materials in modern civilization.

Modern developments. Formal education in forestry began about 1825 when private forestry schools were established. These were the outgrowth of the old master schools such as Cotta Master School, which developed into the forestry college at Tharandt—one of the leading forestry schools in Germany. The National School of Forestry was established in Nancy, Fr., in 1825.

During the 19th century the reputation of German foresters stood so high that they were employed in most continental European countries. Early American foresters, including the great conservation pioneer Gifford Pinchot, gained their training at European centres. But the doctrine of responsible control had to fight a hard battle against timber merchants who sought quick profits.

The 20th century has seen the steady growth of national forest laws and policies designed to protect woodlands as enduring assets. Beginning in the 1940s vast land reclamation was undertaken by Greece, Israel, Italy, Spain, and the Maghrib countries of North Africa to restore forests to the slopes laid bare by past abuse. The main objective of the tree planting is to save what remains of the soil and to protect the watersheds. In China, where forests once extended over 30 percent of the land, centuries of overcutting, overgrazing, and fires reduced this proportion to approximately 7 percent. China has taken major steps to improve land use, including construction of reservoirs and a huge forest planting program, which reported the planting of 15,750,000 hectares between 1950 and 1957 alone.

Forest policies around the world

The character of forest policies around the world reflects national political philosophies. In Communist countries all forests are owned by the state. In the United States both the federal and the state governments have deemed it prudent to hold substantial areas of natural forest, while allowing commercial companies and private individuals to own other areas outright. Similar patterns of ownership are found throughout most of Asia, western Europe, and the Commonwealth countries. In Japan the extensive forests are largely state owned. Tribal ownership is found in many African countries and proves a serious obstacle to effective modern management. International cooperation is effected by the Forestry Department of the United Nations' Food and Agriculture Organization, with headquarters in Rome.

Development of U.S. policies. The history of forestry in the United States followed the same path as forestry in Europe—land clearing, repeated burning, overcutting, and overgrazing—until a bill was passed by Congress in 1891 authorizing the president to set apart from the public domain reserves of forested land. In 1905 an act of Congress, with strong encouragement from President Theodore Roosevelt, transferred the Bureau of Forestry from the Department of the Interior to the Department of Agriculture. Gifford Pinchot, who had been chief of the bureau, was made chief of the newly named Forest Service. Pinchot developed the U.S. Forest Service into a federal agency that today is recognized worldwide for its research, education, and land and forest management expertise. On the state level the Morrill Act of 1862 provided for federal-state cooperative programs in which the federal government granted first land, then money, to the states for the establishment of technical agricultural colleges. The Weeks Act of 1911 authorized the federal government to assist the states in protecting forests from fire, and the Clark-McNary Act of 1924 extended the provisions of the Weeks Act to include cooperation in forest extension, planting, and assistance to forest owners.

Civilian Conservation Corps

During the Great Depression of the 1930s the interests of forestry were served most imaginatively and thoroughly by the Civilian Conservation Corps (CCC), which planted trees, fought forest fires, and improved access to woodlands across the United States. The CCC, rooted in the system of public works initiated by President Franklin D. Roosevelt, continued until 1942, acquainting many people with forestry as a major government activity.

The complete mobilization of resources for the U.S. involvement in World Wars I and II and the pent-up demand for consumer goods made heavy demands on forest resources and industries. As a result, forestry on a national basis entered a period of the most rapid advance since the turn of the century. This time the advance was stimulated by the need for forest products and by the conviction on the part of the major timber companies that they must protect their raw material supply. To protect the forests from growing pressure from single-interest groups, Congress passed the Multiple Use-Sustained Yield Act of 1960. This act directed that the national forests be managed under principles of multiple use so as to produce a sustained yield of products and services. The Bureau of Outdoor Recreation was established shortly thereafter in the Department of the Interior. The Land and Water Conservation Fund, established in 1964, launched a comprehensive program for planning and developing outdoor recreation facilities. State forestry programs had their beginnings in the United States during colonial times, but it was the Weeks and Clark-McNary laws that provided the impetus to develop recognized state forestry departments. The Smith-Lever Act of 1914 allotted funds through the state agricultural colleges for extension work in forestry. Initial programs emphasized tree planting and demonstrations, but today all aspects of forestry and natural and related resources are included.

Industrial forestry began around 1912 when Finch, Pruyn, and Company started a forestry program on its Adirondack holding in New York. Trees to be cut were marked by foresters, and the cutting budget was projected on a sustained-yield basis. A rapid expansion of company forestry programs in the northeastern United States began in the late 1920s and early 1930s. Following World War II, paper companies expanded rapidly throughout the South and West and to a lesser extent in the Northeast. Pulp and paper companies were quick to recognize the benefits to be realized from research financed by the Forest Service and by universities in such fields as tree physiology, entomology, genetics, and tree improvement. A few companies established their own experimental forests and research teams.

Citizens' organizations

The cause of forestry in the United States also has been advanced by citizens' organizations. These vary from lay and youth organizations, such as the Boy Scouts and garden clubs, to the nation's most prestigious scientific societies. The American Association for the Advancement of Science stimulated Congress in 1876 to embark on a sustained federal forestry program. The National Academy of Sciences 1896 report on forest reserves began its long involvement in forest conservation. The Society of American Foresters, founded in 1900, together with its sister societies in Canada and Mexico, represents the profession of forestry in North America.

CLASSIFICATION AND DISTRIBUTION OF FORESTS

Botanical classification places forest trees into two main groups, Gymnospermae and Angiospermae. The gymnosperms consist exclusively of trees and woody shrubs, whereas the angiosperms are a diverse group of plants that include trees and shrubs as well as grasses and herbaceous plants. The gymnosperms probably gave rise to the angiosperms, although the manner in which this took place is disputed.

Gymnosperms. The gymnosperms are of very ancient lineage and include the earliest trees on the evolutionary scale. With certain exceptions, the seeds of gymnosperms are borne in cones, where they develop naked or exposed on the upper surface of the cone scales. The wood of these trees has a simple structure. Many species are extinct, such as the tree ferns of the Carboniferous Period (280,000,000 to 345,000,000 years ago), and are known only as fossils. The ginkgo, or maidenhair tree, is the sole survivor of an entire order of gymnosperms, the Ginkgoales. Among the gymnosperms, the most important and numerous forest trees are the conifers, also known as softwoods.

This group includes the well-known pines, spruces, firs, cedars, junipers, hemlocks, and sequoias. These species are so dominant in the gymnosperm class that forests of gymnosperm trees are typically called coniferous forests. Except for the ginkgo, larches, and bald cypress, all gymnosperms are evergreen.

Angiosperms. The angiosperms constitute the dominant plant life of the present geologic era. They are the products of a long line of evolutionary development that has culminated in the highly specialized organ of reproduction known as the flower, in which seed development occurs within an ovary. This group includes a large variety of broad-leaved trees, most with a deciduous leaf habit but some that are evergreen. The angiosperms are further divided into monocots and dicots. Trees are represented in both groups.

Monocots. The monocots include principally the palms and bamboos. Palm trees form extensive savannas in certain tropical and subtropical zones but are more usually seen along watersides or in plantations.

Palm trees have no growth rings, being made up of spirally arranged bundles of fibres, giving a light, spongy wood. Palms are valuable, however, for their various fruits (coconuts, dates, and palm kernels) and leaf products (carnauba wax, raffia, and thatching and walling materials for houses in the tropics).

Bamboo

Another form of tropical monocotyledonous forest is the bamboo thicket, common in Asia, composed of giant woody grasses. One of the most versatile plants in the world, bamboo is valuable as a construction material, as well as for hundreds of other applications. Its young shoots are eaten as vegetables and are a valuable source of certain enzymes.

Dicots. Finally, a more highly evolved group of forest trees is the dicots, or broad-leaved trees, also called hardwoods. Their wood structure is complex, and each sort of broad-leaved lumber has characteristic properties that fit it for particular uses.

Occurrence and distribution. Approximately 4,000,000,000 hectares, or about one-third of the total land area in the world, is covered with closed forests of broad-leaved and coniferous species and open forests or savannas (Table 1). Because of the varying characteristics of individual tree species, the kind and distribution of the world's forests are largely determined by local conditions. Each combination of temperature, rainfall, and soil has a peculiar association of trees and other vegetation that are best equipped to compete with other plants for that site. The open forest is characteristically a tropical grassland, often disturbed by fire, with forest along streams and scattered individual trees or small groves. Closed thorn forests usually appear adjacent to the savannas. In general, coniferous forests are found in the cooler, drier areas, and the broad-leaved species are predominant in the warmer, usually moister parts of the world. Tropical forests consist almost exclusively of broad-leaved species. Mixed broad-leaved and coniferous forests are found near the boundaries between these two climatic zones.

The northern coniferous forests

Coniferous forests are largely found in the temperate climate of the Northern Hemisphere, where they cover approximately 1,100,000,000 hectares; some 85 percent of them are in North America and the erstwhile Soviet Union (Figure 1). The northern coniferous forest, or taiga, extends across North America from the Pacific to the Atlantic, across northern Europe through Scandinavia and Russia, and across Asia through Siberia to Mongolia, northern China, and northern Japan. It has outliers along all the temperate mountain ranges, including the Rockies, the Appalachians, the Alps, the Urals, and the Himalayas. Its principal trees are spruces (of the genus *Picea*), northern pines (*Pinus*), silver firs (*Abies*), Douglas firs (*Pseudotsuga*), hemlocks (*Tsuga*), and larches (*Larix*). Together these northern softwood forests form a world resource of tremendous importance, yielding the bulk of the lumber and pulpwood handled commercially. Northern conifers from many lands are extensively planted in Europe, including the British Isles.

*In millions of hectares.

The southern coniferous forest has a discontinuous spread through the southern part of the Northern Hemisphere, including California, the southeastern states of the United States, the Mediterranean lands of southern Europe, North Africa, Asia Minor, parts of the Asian mainland, and southern Japan. Pines are the principal trees, along with cypresses (*Cupressus* and *Chamaecyparis*), cedars (*Cedrus*), and redwoods and mammoth trees (*Sequoia* and *Sequoiadendron*). Certain southern pines such as the California Monterey pine (*Pinus radiata*) grow poorly in their native habitat but exceptionally fast when planted in subtropical Europe, Africa, New Zealand, and Australia.

In addition to the plantations of introduced pines, small areas of coniferous forest are found in the Southern Hemisphere, notably the Chile pine, *Araucaria araucana,* in the Andes; hoop pine, or bunyabunya, *Araucaria bidwillii,* in Australia; and kauri pine, *Agathis australis,* in New Zealand.

The dicotyledonous broad-leaved species form three characteristic types of forests: temperate deciduous, subtropical evergreen, and tropical evergreen.

Temperate deciduous broad-leaved forests are made up of the summer-green trees of North America, northern Europe, and the temperate regions of Asia and South America. Characteristic trees are oaks (*Quercus* species), beeches (*Fagus* and *Nothofagus*), ash trees (*Fraxinus*), birches (*Betula*), elms (*Ulmus*), alders (*Alnus*), and sweet chestnuts (*Castanea*). Temperate broad-leaved trees expand their foliage in spring, grow rapidly in summer, and shed all their leaves each fall.

Subtropical evergreen broad-leaved forests grow largely in countries with a Mediterranean type of climate—*i.e.,* hot, dry summers and cool, moist winters. Their trees have characteristic thick, hard-surfaced, leathery-textured leaves with waxy coatings that enable them to resist water loss during summer droughts. Their evergreen habit enables them to make use of moist winters. Typical trees are the evergreen oaks, species of *Quercus,* and the madrone, or *Arbutus,* while in Australia most evergreen broadleaf trees are species of *Eucalyptus.* Few evergreen broadleaf trees have high timber value, and many are little more than scrub, highly inflammable during hot, dry summers. Their world distribution embraces California; the southeastern states of the United States; Mexico; parts of Chile and Argentina; the Mediterranean shores of Europe, Asia, and North Africa; South Africa; and most of Australia.

Tropical rain forests

Tropical evergreen broad-leaved forests, or tropical rain forests, grow in the hot, humid belt of high rainfall that follows the Equator around the globe. They occur in West and Central Africa, South Asia, the northern zone of Australia, and in Central and South America. Where they extend into regions of seasonal rainfall, such as monsoon zones, they become less truly evergreen, holding many trees that stand leafless during the short dry seasons. Tropical rain forests hold a great variety of tree species. A few of the timbers, such as teak, *Tectona grandis,* in India, and mahogany, *Swietenia macrophylla,* in Central America, have uniquely useful properties or ornamental appearance and hence a high commercial value. Balsa, *Ochroma pyramidale,* from Central America, is the lightest timber known; it is used for rafts, aircraft construction, and insulation against noise, heat, and cold.

Trees outside areas classified as forestland, such as those in windbreaks, along rights-of-way, or around farm fields, are also important resources, especially in densely populated areas. For example, some 20 percent of Rwanda's farmland is maintained by farmers as woodlots and wooded pastures. These roughly 200,000 hectares of dispersed trees exceed the combined area of the country's natural forests and state and communal plantations. In the Kakamega District of Kenya more than 90 percent of the farms have scattered trees maintained for animal fodder and fuelwood. Of the 7,200,000,000 trees planted in the densely settled plains region of China, 5,800,000,000 have been planted around homes and in villages, with each household tending an average of 74 trees. Even in France, where trees are not used much for fuelwood, trees outside the forests occupy 883,000 hectares. There are no good estimates of the worldwide totals of such scattered trees, but their existence provides many locally useful products and extends the resources in the forested areas.

PURPOSES AND TECHNIQUES OF FOREST MANAGEMENT

Multiple-use concept. The forests of the world provide numerous amenities in addition to being a source of wood products. The various public, industrial, and private owners of forestland may have quite different objectives for the forest resources they control. Industrial and private owners may be most interested in producing a harvestable product for a processing mill. However, they also may want other benefits, such as forage for grazing animals, watershed protection, recreational use, and wildlife habitat. On public lands the multiple-use land management concept has become the guiding principle for enlightened foresters. This is a complex ecological and sociological concept in contrast to the single-use principle of the past. The challenge, in the words of Gifford Pinchot, is to "ensure the greatest good for the most people over the long run." Thus timber production may have top priority in certain areas, but in others, such as those near large population centres, recreational values, for example, may have high priority. Multiple use calls for exceptional skill on the part of forest managers.

Sustained yield. Forest management originated in the desire of the large central European landowners to secure dependable income to maintain their castles and retinues of servants. Today forest management is still primarily economic in essence, because modern forest industries, mainly sawmilling and paper manufacture, can be efficient only on a continuous-operation basis.

Rotation periods

Foresters think in long time scales, in line with the long life of their renewable crop. However, it is possible that a forest can be managed in such a way that a modest timber crop may be harvested indefinitely year after year if annual harvest and the losses due to fire, insects, diseases, and other destructive agents are counterbalanced by annual growth. This is the sustained-yield concept. An important element is the rotation, or age to which each crop can be grown before it is succeeded by the next one. Examples of short rotation periods in the subtropics are seven years for leucaena for fuelwood, 10 years for eucalyptus, and 20 years for pine for pulpwood. Here a sustained yield could in theory be obtained simply by felling one-tenth of the eucalyptus forest each year and replanting it. Rotation periods for pulpwood in northern Europe and North America extend to 50 years. Softwood sawlogs often need 100 years to reach an economic size, while rotation periods for broad-leaved trees, such as oak and beech, in central Europe, may extend to two centuries. Over so long a growing spell only part of the lumber yield is obtained by the clear-cutting of a small fraction of the forest each year. The rest is secured by systematically thinning out the whole forest periodically.

Sustained-yield principles are likewise applied to minor forest produce. Turpentine and pitch, also known as naval stores, are obtained by the systematic tapping of the lower trunk of certain subtropical pines. Successive cuts with a chisellike tool every few days during a succession of summers eventually kill the trees. To ensure continued yields, crops of young pines are raised rotationally to replace those felled. A similar system is followed for Para rubber, *Hevea brasiliensis,* grown in plantations.

Forest products. The culture of trees in natural forests and plantations for the yield of lumber, pulp, chips, and specialty products is a principal management objective. In many parts of the world the harvest of wood for firewood and charcoal is the dominant use, and these products are often in short supply. Timber stands must be felled and regenerated in an orderly sequence to meet continuing industrial demands.

Silvics

Silviculture. Silviculture is the branch of forestry concerned with the theory and practice of controlling forest establishment, composition, and growth. Like forestry itself, silviculture is an applied science that rests ultimately upon the more fundamental natural and social sciences. The immediate foundation of silviculture in the natural sciences is the field of silvics, which deals with the laws underlying the growth and development of single trees and of the forest as a biologic unit. Growth, in turn, depends on local soils and climate, competition from other vegetation, and interrelations with animals, insects, and other organisms, both beneficial and destructive. The efficient practice of silviculture demands knowledge of such fields as ecology, plant physiology, entomology, and soil science and is concerned with the economic as well as the biologic aspects of forestry. The implicit objective of forestry is to make the forest useful to man.

The practice of silviculture is divided into three areas: methods of reproduction, intermediate cuttings, and protection. In every forest the time comes when it is desirable to harvest a portion of the timber and to replace the trees removed with others of a new generation. The act of replacing old trees, either naturally or artificially, is called regeneration or reproduction, and these two terms also refer to the new growth that develops. The period of regeneration begins when preparatory measures are initiated and does not end until young trees have become established in acceptable numbers and are fully adjusted to the new environment. The rotation is the period during which a single crop or generation is allowed to grow.

Intermediate cuttings are various types of cuttings made during the development of the forest—*i.e.,* from the reproduction stage to maturity. These cuttings or thinnings are made to improve the existing stand of trees, to regulate growth, and to provide early financial returns, without any effort directed at regeneration. Intermediate cuttings are aimed primarily at controlling growth through adjustments in stand density, the regulation of species composition, and selection of individuals that will make up the harvest trees. Protection of the stand against fire, insects, fungi, animals, and atmospheric disturbances is as much a part of silviculture as is harvesting, regenerating, and tending the forest crop.

Silvicultural systems are divided into those employing natural regeneration, whereby tree crops are renewed by natural seeding or occasionally sprout regrowth, and those involving artificial regeneration, whereby trees are raised from seed or cuttings. Natural regeneration is easier but may be slow and irregular; it can only renew existing forests with the same sorts of tree that grew before. Artificial regeneration needs more effort, yet can prove quicker, more even, and in the long run more economical. It permits the introduction of new sorts of trees or better strains of the preexisting ones.

Natural regeneration. In established forests the selective cutting of marketable timber, taking either one tree at a time (single-tree selection) or a number of trees in a cluster (group selection) and leaving gaps in which replacements can grow up from natural seedlings, can prove economical and also ensure the best possible use of available soil, light, and growing space. The best examples of single-tree-selection forests are found in Switzerland, on slopes where any clear felling could lead quickly to soil erosion and avalanches.

Alternative methods

Alternative methods of natural regeneration deal with areas of land as units, rather than with single trees. One highly effective example is employed in the Douglas fir forests along the Pacific slope of Canada and the western United States. Logging by powerful yarding machines, using overhead cables, creates wedge-shaped gaps of cleared ground. The surrounding forest is left standing for many years in order to provide shelter and seed. Abundant seed is carried by wind on to the cleared land and gives rise, in a few years, to a full crop of seedling firs. After these have reached seed-bearing age, the areas previously left standing may be removed in their turn. Similar systems using a pattern of strips cut across the forest, or circular plots gradually extended until they meet and coalesce, are employed in France and Germany.

A silvicultural system employing practices of short rotation (five to 10 years) and intensive culture (fertilization, weed, and insect and disease control) with superior genotypes relies on coppice, or regeneration from sprouts arising from stumps of felled trees, as the method of regeneration of the new crop and is characterized by high productivity.

Artificial regeneration. Artificial regeneration is accomplished by the planting of seedlings (the most common method) or by the direct planting of seeds. Direct seeding is reserved for remote or inaccessible areas where seedling planting is not cost-effective. A few tree species, such as poplars (*Populus* species) and willows (*Salix* species), are artificially reproduced from cuttings. Most forest planting in North America involves the conifers, especially the pines, spruces, and Douglas fir, because of the prospects of successful establishment and high financial yield. The amount of hardwood planted worldwide has increased from earlier periods, with major gains in tropical hardwoods (*Eucalyptus* species, *Gmelina* species) and high value temperate species.

Artificial regeneration offers greater opportunity than natural regeneration to modify the genetic constitution of stands. The most important decision made in artificial regeneration is the selection of the species used in each new stand. The species chosen should be adapted to the site. The most successful introductions are obtained by moving species to the same latitude and position on the continent that they occupied in their native habitat. For example, many conifers of the western coasts of North America have been successful at the same latitudes in western Europe. The forest economy of many countries in the Southern Hemisphere is dependent on pines introduced from localities of comparable climate in the southern United States, California, and Mexico.

Seed orchards

The variability of seed quantity and quality and the demand for superior genotypes has led to the creation of seed orchards, stands of trees selected for superior genetic characteristics, which are cultivated to produce large quantities of seed. Most kinds of seed can be stored in sealed containers in refrigerators at temperatures near freezing for several years without a significant loss in viability. For some species, a brief period of cold storage may be necessary for the seeds to germinate; this stratification treatment is needed to satisfy the dormancy requirement of some temperate-zone species.

Direct sowing of harvested seed in the forest or on open land is not a common practice because of forest seed-eaters (mice, squirrels, birds) and the problem of weed growth. Tree seedlings are therefore raised in forest nurseries, where effective protection is possible. These seedlings almost invariably come from seed, although vegetative propagation from rooted cuttings is a useful technique of perpetuating valuable strains of certain species. Seedlings grown in raised seedbeds are removed from the nursery soil when large enough and are bare-rooted when planted in the field. Seedlings grown in individual containers have an intact root system encapsulated in a soil plug for planting. In either case, the system can be highly mechanized. To enhance seedling quality, the seedbeds or container media are inoculated with specific microorganisms that form symbiotic relationships with the seedlings. These microorganisms include certain fungi, which form mycorrhizae with the roots and improve nutrient and water uptake, and nitrogen-fixing organisms such as *Rhizobium* species and *Frankia* species, which contribute nutrients. Selective herbicides, insecticides, and fungicides are applied before or after seedling emergence to keep the developing seedlings free of weeds, insects, and disease.

Many tree seedlings are suitable for field planting after a few months in a containerized seedling nursery or after one to two years in a seedbed. Slow-growing species are transplanted by hand or machine during the dormant season to transplant beds where they are root-pruned and fertilized to stimulate top growth and the development of a bushy root system, characteristics essential for survival in field planting. The mechanized operation is highly efficient. One machine and four workers can transplant 30,000–40,000 seedlings each working day. Weeds are controlled during the transplant stage by chemical herbicides that inhibit weed seed germination or growth or by mechanical harrows drawn between the rows.

Seedling preparation

In preparation for field planting, dormant nursery-grown seedlings are undercut with a sharpened steel blade and removed from the bed by hand or by a mechanized vibrating lifter and conveyor belt system. Roots of seedlings lifted in autumn are packed with moistened sphagnum moss, and the bundles are stored in refrigerated coolers. Alternatively, seedlings may be placed in a trench, or heeling-in bed, and covered with soil and mulch until spring. At the time of lifting, seedlings should be culled to eliminate those that will not survive after planting—*i.e.,* seedlings infested with insects or disease, badly damaged in lifting and handling, having distinctly poor root systems, or falling below minimum size standards. It is imperative that the seedlings be kept cool and the root systems moist in all phases of the lifting, storage, transport, and planting processes.

Container-grown seedlings are culled in a manner similar to the bare-rooted stock and in most cases are shipped in the containers in which they were produced. The container method, which has traditionally been used in the tropics or in locations that are hot and dry, has become the principal method of seedling production in Canada, Scandinavia, and portions of continental Europe, Japan, and China.

Planting tree seedlings is one of the most costly investments in the production of a forest crop. The success of a whole rotation is often determined by the soundness of decisions made about planting. These decisions concern the selection of the planting stock, the density of the planting, the use of mixed plantings, the season of planting, preparation of the site prior to planting, and even the method of planting. In temperate climates planting is generally conducted from late winter to late spring, but the use of container-grown seedlings extends the planting season into the early summer and includes a period in early autumn.

On level ground, machine planting is preferred over hand planting. A planting machine forms a groove in the soil in which seedlings are placed at specified intervals; a set of blades then cuts into the soil around the planted seedling, and a set of packing wheels firms the soil around it. A planting machine pulled behind a single tractor on prepared level ground can set 8,000–10,000 seedlings per day. On steep slopes, broken or rocky ground, or amid tree stumps and tops, planting is done by hand. The planter uses a spade, planting bar, or mattock (or a variation of one of these) to cut a notch, or dig a pit, into which the seedling roots are inserted. Soil is then replaced and stamped firmly around the base of the seedling.

Weed control

During the following growing season, and possibly two to three years thereafter, weed control may be essential for the survival and early growth of the planted seedling. Weeds may be removed by hand with a sharp tool or hoe or by other mechanical means such as mowing or cultivating between the planted rows. Herbicides may offer a more effective and efficient means of weed control. While care must be exercised to shield the tree from many chemicals, compounds are available that kill unwanted vegetation but do not harm the tree seedling. In some regions the lower branches of conifers and certain highly valued hardwoods are pruned from saplings and young trees to improve the quality and value of the main stem and improve access into the plantation. Otherwise, the artificially established plantation needs, and receives, no more attention than does the naturally regenerated crop.

Until the 20th century foresters usually accepted the land much as they found it. Their reaction to infertile soil was to plant aggressive species of trees, regardless of their potential market value, and to accept lower returns in plant production. Development of modern machines and a growing understanding of plant nutrition and soil chemistry now enable foresters to improve sites much as a farmer does and thereby to increase output substantially. Mechanical draining, using tractor-drawn plows to create deep open drains and so aerate the soil, is now usual on the peaty swamps of Europe, especially in Finland. On the hard heathlands of Great Britain, 120,000 hectares of new afforestation land were broken up after 1940 with sturdy plows designed to turn over firmly compacted soil layers. Plowing facilitates penetration of air, water, and tree roots, checks weed growth, and lessens fire hazard. So far it has usually been confined to strips for each row of trees, but full plowing as done on a farm promises further advantages.

In the poorly drained Great Lakes states and in coastal areas in the southeastern and southern United States, sites are prepared by a bedding plow, which creates an alternative ridge and valley surface that improves soil drainage, aeration, and nutrient availability. Subsequent to bedding, seedlings are planted on the ridge or bed. Because forest crops are rarely irrigated (returns are too low for the capital cost invested), forest plantings on droughty sites require a careful selection of the species and the time for planting and an effective weed control program.

Tree nutrition

The fundamental relationship between mineral nutrition and growth is the same for trees as for other plants. An understanding of forest tree nutrition requires recognition of factors distinctive to forests: (1) The nutrient demands of the plantation vary from season to season and with the developmental stage of the stand. During the life of a forest tree crop, large quantities of nutrients are returned to the soil in organic matter, which is, in turn, mineralized and made available for reuse by the same or the following crop. (2) Retranslocation of absorbed nutrients is highly developed in trees; *i.e.*, nutrients in leaves move back into stems prior to fall leaf drop and then move into new leaves in the spring. (3) Except for the first year after planting, trees start the growing season with a developed framework for photosynthesis and an established root system for nutrient and water uptake. (4) The use of soil resources such as water and nutrients by trees may often be strongly influenced by mechanisms involved in adaptations for survival from one season to another, rather than in growth.

Judicious management of nutrition ensures not only increased productivity of existing forests but also sustained productivity over many rotations. In southern Australia, for example, declines in yield of 25–30 percent in second rotation radiata pine (*Pinus radiata*) plantations have been corrected by a number of means, including intensive silviculture (site preparation, weed control, fertilization) during the early stages, retention and management of forest debris (leaves, branches, etc.) to conserve nutrients, and intercropping with annual legumes, which supply nitrogen and other nutrients.

Range and forage. Important among the broad spectrum of forest resources are the understory plants that can provide forage for grazing animals, both domestic and wild. Grazing livestock are useful to the forest manager. Dense old-growth forest or vigorous second-growth stands with closed canopies generally have sparse, low-quality forage. Large forest management units, however, generally contain extensive logged or burned areas where understory forage plants temporarily dominate the site. These areas are transitory since the tree canopies close in 10 to 20 years, but they can provide good forage until canopy closure. Cutting cycles in the managed forest and even wildfires provide a continuing grazing resource that shifts from one location to another. In addition, open meadows occurring in valley bottoms, open forests on shallow soils, and grassland balds on windswept ridge tops greatly enrich the grazing potential of the forest. Grazing fees offset the long-term investments that must be carried in renewing the forest.

Hardwood forests are more susceptible than coniferous forests to grazing damage. The current year's growth on broad-leaved trees provides palatable forage during most seasons of the year, whereas coniferous needles are much less palatable. Uncontrolled livestock-grazing in some parts of the world has been particularly devastating to forests and is a serious problem.

Recreation activities

Recreation and wildlife. From the earliest times human beings have looked to the forests for recreation. Today, recreation in forests assumes ever-growing importance with the growth of cities whose inhabitants need a change of scene, fresh air, and freedom to wander, as a relief to the stresses of industrial and commercial life. Imaginative planning is essential to ensure that people actually find what they are seeking without damage to the forest environment or conflict with the pleasures of others. The most popular outdoor recreation activities utilize forestland and include hunting and fishing, picnicking and camping, hiking, mountain climbing, driving for pleasure, boating and other water sports, winter sports, photography, and nature study. The challenge is to balance the varied demands for recreational use with the other forest uses.

For many recreationists the main attraction of the woods is the abundance of animal and plant life. The forest manager must attempt to satisfy the diverse needs of hunters and sportsmen, outdoorsmen, and preservationists. This requires a broad expertise drawing on principles from the social sciences, natural history, wildlife management, landscape design, law, and public administration, among other disciplines.

Recreation management includes visitor management as well as resource management. Reasonably accurate assessments of the type and amount of use that areas receive are important to allow for efficient allocation of budgets and employee time and to ensure that the degree of use does not cause excessive impacts on resources and thus destroy the recreational value of the site. Skillful location of roads, picnic points, parking lots, and campgrounds ensures that the great majority of visitors congregate in relatively small portions of a large forest. Visitor management for some situations can be aided by use of computer-generated simulation models.

Some types of recreation require intensive management and special amenities. Vehicular camping facilities, for example, are designed for intensive use by large numbers of people and typically provide electrical hookups, toilets, showers, picnic tables, fireplaces, garbage receptacles, directional and interpretive signs, and play areas. These features must be durable and easily maintained. Downhill ski areas are most popular when well equipped with various runs, lifts, restaurants, and lodges. Other types of recreation, such as trail hiking and cross-country skiing, demand larger tracts of land but fewer improvements. Wilderness areas afford the personal challenge and serenity of backpacking, tent camping, and canoeing.

The interpretation of what visitors see in the forests has become a growing activity of most forest services. Nature trails, guidebooks, signposts, interpretive museums, and information stations assist visitors who come to learn as well as to enjoy.

Forests contain natural habitats for a wide range of wildlife, from the elks, wolves, lynxes, and bears of northern coniferous forests to the antelopes, giraffes, elephants, lions, and tigers of tropical savannas and jungles. Certain birds, such as pheasants, wood grouse, and quail, have high sporting value, while others are cherished for attractive song, appearance, or rarity. Many endangered species depend on forest habitats that are carefully protected by national and international laws.

Forest managers must attend to the interrelated, and sometimes directly opposed, wildlife interests of hunters, conservationists, and farmers. Obviously the same animal can present a different aspect to each group. A Bengal tiger, for example, provides a biologist with a classic example of a carnivorous beast living in harmony with a jungle environment and restraining its main prey, deer, from undue increase in numbers. But to a village peasant it is a menace to his cows and goats and a threat to the safety of himself and his family, while a game hunter regards it as a magnificent quarry demanding all his skill. The needs of the forest itself require the numbers of grazing and browsing animals to be kept to a tolerable level. Otherwise renewal of tree crops becomes impossible.

Wildlife requirements

Virtually every change that occurs in a forest benefits some wildlife species and harms others. Some species require a diversity of conditions; one type for feeding, another for nesting, and yet another for cover. Some have very specific requirements essential to their existence, whereas others have a broad range of tolerance. In any case, the life history characteristics of the species must be known in order for the resource manager to plan and implement practices necessary for the well-being of the species. Sometimes the best management involves increasing the forest edge habitat, frequented by many kinds of wildlife. Forest edge improvement may be integrated with timber harvesting and the construction of fire lanes and logging roads. Because food and cover for wildlife are often more plentiful in the early stages of forest development, retardation of succession by prescribed burning may be beneficial to wildlife. Food crops may be planted in certain areas to improve the wildlife-carrying capacity. Adjustments are often made by foresters in cutting procedures, rotation age, regeneration methods, and other practices to accommodate the food and cover needs of wildlife and fish. Certain areas may be managed exclusively for wildlife, particularly in situations where habitat for endangered species must be protected.

In virtually every country the sporting aspect of woodland wildlife management is controlled, to some degree, by general game laws, which also apply outside the forests. These prescribe licenses for firearms and the taking of specified birds and beasts; they usually lay down closed seasons during which certain game may not be shot and also set limits to the sportsman's bag of rare species. In the United States a peculiar situation exists whereby the game legislation of the separate states applies unchanged over most publicly owned forests. In other countries the forest managers are in a stronger position, since local game laws are adjusted to their particular requirements.

Watershed management and erosion control. Not only is the presence of water in soils essential to the growth of forests, but improved water yield and quality are becoming increasingly important management objectives on many forested lands. Forests and their associated soils and litter layers are excellent filters as well as sponges, and water that passes through this system is relatively pure. Forest disturbances of various kinds can speed up the movement of water from the system and, in effect, reduce the filtering action. While disturbances are inevitable, in most instances they need not contribute to poor water quality.

In mountainous territory the value of forests for watershed and erosion protection commonly exceeds their value as sources of lumber or places of recreation. The classic example is found in Switzerland and the neighbouring Alpine regions where the existence of pastoral settlements in the valley is wholly dependent on the maintenance of continuous forest cover on the foothills of the great peaks. This is combined skillfully with limited lumbering and widespread recreational use by tourists.

The guiding principle of management where erosion threatens is therefore the maintenance of continual cover. Ideally, this is achieved by single-stem harvesting; only one tree is felled at any one point, and the small gap so created is soon closed by the outward growth of its neighbours.

The progress of water, from the time of precipitation until it is returned to the atmosphere and is again ready to be precipitated, is called the hydrologic cycle. The properties of the soil plant system provide mechanisms that regulate interception, flow, and storage of water in the cycle. The water that moves downward into the soil, or infiltrates, is the difference between precipitation and the losses due to canopy interception, forest floor interception, and runoff. The amount of water stored in the soil is largely dependent on the physical properties of the soil, its depth, and the amount of water lost due to evaporation from the soil surface and transpiration from plants (evapotranspiration). Transpiration is the water absorbed by plant roots that is subsequently evaporated from their leaf surfaces. Deep forest soils have a high water-storage capacity. Unless they are very porous and drain freely, they have a water table below which the subsoil is saturated. The depth of the water table varies seasonally and is higher during periods of low evapotranspiration. Removal of the forest canopy in wet areas also raises the water table. Most tree roots need air to survive and cannot exploit soil below the water table. The drainage of land having a high water table usually increases the productivity of the forest.

Transpiration

When incoming precipitation exceeds the soil's water-storage capacity, the excess water flows from the soil and can be measured as streamflow. The water yield of a forest is a measure of the balance between incoming precipitation and outflow of water as streamflow. The amount of increase in water yield depends on annual precipitation as well as the type and amount of overstory vegetation removed. As forests regrow following cutting, increases in streamflow decline as a result of increased transpirational losses. Streamflow declines are greater in areas that are restocked with conifers than in those restocked with hardwoods. This results from greater transpiration losses during the winter months from coniferous species.

Despite the uncertain balance of water gain and loss, forests offer the most desirable cover for water management strategies. Water yields are gradual, reliable, and uniform, as contrasted to the rapid flows of short duration characteristic of sparsely vegetated land. Unforested land sheds water swiftly, causing sudden rises in the rivers below. Over a large river system, such as that of the Mississippi, forests are a definite advantage since they lessen the risk of floods. They also provide conditions more favourable to fishing and navigation than does unforested land. All natural streams contain varying amounts of dissolved and suspended matter, although streams issuing from undisturbed watersheds are ordinarily of high quality. Waters from forested areas are not only low in foreign substances, but they also are relatively high in oxygen and low in temperature. Nonetheless, some deterioration of stream quality can be noted during and immediately after clearcut harvesting, even under the best logging conditions. The potential for water-quality degradation following timber harvest may involve turbidity (suspended solids) as well as increases in temperature and nutrient content. Sediment arising from logging roads is the major water-quality problem related to forest activities in many areas.

The belief that forests increase rainfall has not been substantiated by scientific inquiry. Local effects can, however, prove substantial, particularly in semiarid regions where every millimetre of rain counts. The air above a forest, as contrasted with grassland, remains relatively cool and humid on hot days, so that showers are more frequent. Fog belts, such as those found along the Pacific seaboard of North America and around the peaks of the Canary Islands, give significant water yields through the interception of water vapour by tree foliage. The vapour condenses and falls in a process described as fog drip.

Fire prevention and control. A forest fire is unenclosed and freely spreading combustion that consumes the natural fuels of a forest; *i.e.,* duff, grass, weeds, brush, and trees. Forest fires occur in three principal forms, the distinctions

Types of forest fires

depending essentially on their mode of spread and their position in relation to the ground surface. Surface fires burn surface litter, other loose debris of the forest floor, and small vegetation; a surface fire may, and often does, burn taller vegetation and tree crowns as it progresses. Crown fires advance through the tops of trees or shrubs more or less independently of the surface fire and are the fastest spreading of all forest fires. Ground fires consume the organic material beneath the surface litter of the forest floor; ground fires are the least spectacular and the slowest-moving, but they are often the most destructive of all forest fires and also the most difficult to control.

A forest fire does a number of specific things. First, and perhaps most obviously, it consumes woody material. Second, the heat it creates may kill vegetation and animal life. In most fires, much more is killed, injured, or changed through heat than is consumed by fire. Third, it produces residual mineral products that may cause chemical effects, mostly in relation to the soil. The lethal temperatures for the living tissues of a tree (*i.e.,* the phloem and cambium, which are located under the bark) begin at 49° C (120° F) if exposure is prolonged for one hour. At 64° C (147° F) death is almost instantaneous. The ignition temperature for woody material is approximately 343° C (650° F), with a flame temperature of 870°–980° C (1600°–1800° F).

Forest fires seldom occur in tropical rain forests or in the deciduous broad-leaved forests of the temperate zones. But all coniferous forests, and the evergreen broadleaf trees of hot, dry zones, frequently develop conditions ideally suited to the spread of fire through standing trees. For this, both the air and the fuel must be dry, and the fuel must form an open matrix through which air, smoke, and the gases arising from combustion can quickly pass. Hot, sunny days with low air humidity and steady or strong breezes favour rapid fire spread. In coniferous forests the resinous needles, both living and dead, and fallen branch wood make an ideal fuel bed. The leaves of evergreen broadleaf trees, such as hollies, madrone, evergreen oaks, and eucalyptus, are coated in inflammable wax and blaze fiercely even when green. Once started, fire may travel at speeds of up to 15 kilometres (10 miles) per hour downwind, spreading slowly outward in other directions, until the weather changes or the fuel runs out.

Fire danger rating

Well over 95 percent of all forest fires are caused by people, while lightning strikes are responsible for 1–2 percent. In some countries the setting of fires for clearing cropland is an integral technique of agriculture. In other areas forest fire prevention, including public education, hazard reduction, and law enforcement, consumes a considerable amount of time and money. The two basic steps in preventing forest fires are reducing risk and reducing hazard. Risk is the chance of a fire's starting as determined by the presence of activity of causal agents, most likely human beings. Hazard is reduced by compartmentalizing a forest with firebreaks (alleyways in which all vegetation is removed) and reducing the buildup of fuel (litter, branches, fallen trees, etc.) by controlled burning. In the United States the Forest Service devised a National Fire-Danger Rating System, which is the resultant of both constant and variable fire danger factors that affect the inception, spread, and difficulty of control of fires and the damage they cause.

Effective fire control begins with a field survey and map to identify the areas at risk, delineate them, and define and improve the barriers or firebreaks that may limit fire spread. Natural barriers include rivers, lakes, ridge tops, and tracts of bare land. Artificial barriers can be roads, railways, canals, and power-line tracks, but usually extra firebreaks must be cut to link these and provide wider gaps that fire cannot readily jump. Belts of land from 10 to 20 metres wide are cut clear of trees or left unplanted when a new forest is formed. Sometimes the soil is left bare and cultivated only at intervals to check invasion by weeds. Usually it is sown with an even crop of low perennial grasses or clovers and kept short by mowing or grazing. This checks soil erosion, provides an evergreen fireproof surface, and allows access on foot, by car, or in an emergency by fire-fighting trucks. Surfaced roads, serving also for lumber haulage and access for recreation, are of critical importance in fire fighting. Signposts are needed to guide fire crews unfamiliar with the woods and to mark water supplies and rendezvous points.

Detection is the first step in fire suppression. Many countries have organizations of trained professionals to detect and fight fires; others rely on volunteers or a combination of the two. Tower lookouts are the mainstay of nearly all detection systems, although the use of aircraft and satellites has modified this view in countries with an advanced fire control program. Fire surveillance is essential during seasons of high risk. Towers are set on hilltops where observers equipped with binoculars, maps, and a direction scale determine the compass direction of smoke and notify the fire control base via telephone or radio. If a fire can be seen from two or more towers, its precise position is quickly determined by mapping the intersection of cross bearings. Aircraft are used to detect fires and to carry out reconnaissance of known fires. Aerial surveillance has probably been most successful in detecting lightning-caused fires and is most often employed in areas of relatively low-value lands and inaccessible areas. An aircraft is essentially a moving fire tower, and the problems of detection that apply to a tower also apply to an aircraft; however, new developments in remote-control television, high-resolution photography, heat-sensing devices, film, and radar make fire detection by aircraft and satellite more efficient and location more accurate. Satellites provide a rapid means of collecting and communicating highly precise information in fire detection, location, and appraisal.

The "fire triangle"

Once a fire has been detected, the next step is fire suppression. The first job is to stop or slow the rate of spread of the fire, and the second job is to put it out. The aim of suppression is to minimize damage at a reasonable cost. This does not necessarily mean the same thing as minimizing the area burned, but it is a major goal. Suppression is accomplished by breaking the "fire triangle" of fuel, temperature, and oxygen by robbing the fire of its fuel (by physically removing the combustible material or by making it less flammable through application of dirt, water, or chemicals); by reducing its temperature (through application of dirt, water, or chemicals and partial removal or separation of fuels); and by reducing the available oxygen (by smothering fuels with dirt, water, fog, or chemical substances).

The great majority of all forest fires are contained by professional fire fighters equipped with numerous hand tools (spades, beaters, axes, rakes, power saws, and backpack water pumps). Trained fire crews with light, hand equipment can be carried quickly to a fire by truck, delivered by helicopter, or even dropped by parachute. When necessary, large machines (bulldozers or plows) are used to clear openings, or firebreaks, which stop the spread of the fire (Figure 2). This requires clearing surface and sometimes aerial fuels from a strip of land and then digging down to mineral soil to stop a creeping or surface fire. A control line can also be established by directly extinguishing the fire along the edge or by making fuels nonflammable. In some cases a backfire may be deliberately set between the control line and the oncoming fire to burn out or reduce the fuel supply before the main fire, or head fire, reaches the control line.

Water is the most obvious, efficient, and universal fire extinguisher, but large-scale use of water in fire fighting is limited because it is usually in short supply and application methods are not adequate. For these reasons other materials have been tested for persistence and efficiency in putting out fires. Wetting agents change the physical characteristics of water to increase its penetrating and spreading abilities. Retardants, such as sodium calcium borate, reduce the flammability of wood and therefore its rate of burning. Foaming agents in powder or liquid form can greatly increase the mixture volume and thereby cool, moisten, and insulate the fuel.

Aircraft can quickly carry in water and other chemicals to be dropped or sprayed on the fire. A method developed on Canadian lakes is to fill the floats of a seaplane with water, which is done as it skims the lake on takeoff, and to discharge this through nozzles over the fire.

The prescribed use of fire in forestland management

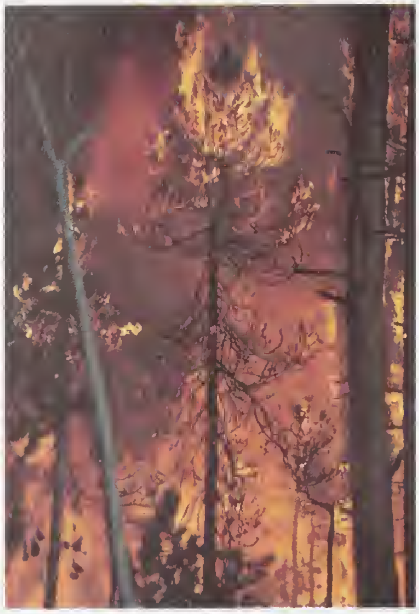

Figure 2: Forest fire in Yellowstone National Park, 1988, one of the most destructive forest fires in the history of the United States.

is approached with understandable reluctance by many foresters and wildland managers. Yet, fire has a place in the management of particular ecosystems. The decision to use fire is usually based on a balancing of pros and cons; *i.e.*, damage, possible or expected, must be weighed against benefits. Under proper circumstances, prescribed burning can be used to prepare seedbeds for natural germination of most tree species, to control insect and disease infestations, to reduce weed competition, to reduce fire hazard, and to manipulate forest cover type.

Insect and disease control. Enormous numbers and varieties of insects, fungi, bacteria, and viruses occur in forests and are adapted to live on or around trees. Many of these are beneficial, and even the destructive ones are usually held in check by their natural enemies or an unfavourable environment. The normal population levels of pest organisms result in limited reduction in tree growth or the total destruction of only a small number of trees in the forest. The losses are generally accepted by foresters as unavoidable and are tolerated as long as the annual destruction does not seriously affect the net annual increase in wood production.

Every part of a growing tree—root, trunk, bark, leaf, flowers, and seeds—is potentially subject throughout every stage of its life to attack by some harmful insect or fungus (Figure 3). Insects actually destroy more standing timber than does any other agent. Bark beetles, including species of *Dendroctonus* and *Ips*, are among the most destructive insects. They bore into the tree and feed just below the bark, where they create tiny channels that disrupt the flow of food to the roots, often killing the tree. Diseases frequently retard growth of trees and are less of a factor in mortality. A particularly destructive disease is caused by fungi that decay the wood of trees. The heartrot fungi gain entrance through any wound resulting from fire scars, broken limbs, or anything else that damages the tree's protective tissue. Were it not for heartrot, a large number of conifers and broad-leaved trees could be left to grow for many more years.

Bark beetles

Insect and disease organisms accidentally introduced to forests from other parts of the world often develop serious epidemic conditions because of the lack of any natural control. Because of rapid global transportation, insects and fungal spores can be spread easily throughout the world and arrive in a healthy condition. The seriousness of the situation cannot be overestimated, and the enforcement and improvement of plant quarantine laws is essential. Typically disasters have arisen where quarantine has failed or has been imposed too late. The American chestnut, *Castanea dentata,* has been virtually wiped out by the chestnut blight fungus, *Endothia parasitica,* which does little harm to related trees in its native China. Elms have suffered severely, both in Europe and in the United States, from the elm disease fungus, *Ceratocystis ulmi,* which was first detected in The Netherlands and is carried from tree to tree by flying beetles. Minute aphids, probably introduced on living plants from Asia, now make it impossible to raise commercial crops of two conifers once valued in Britain, namely, the white pine, *Pinus strobus,* from New England, and the European silver fir, *Abies alba,* native to Switzerland.

Generally the healthier the forest, the more resistant it is to widespread pest attack. Overmature, weak, windthrown, and lightning- or fire-killed trees have little or no defense against infestation and are a factor in the buildup of pest populations. Selective cutting of susceptible trees, thinning that accelerates growth, and other similar long-range forest management practices that stimulate vigorous tree growth are good methods for indirect control of insects and diseases. These practices reduce the host material and breeding grounds of pests that may spread to healthy trees. In regions with a high incidence of a known pest, foresters attempt to avoid serious trouble by planting only trees known to resist existing pests in the regions where the trees are grown. Many forest genetic programs have as a major goal the selection and breeding of trees with insect and disease resistances.

Occasionally the natural conditions that suppress the population of pest organisms change, and outbreaks in forests may reach epidemic proportions. Even-aged stands and plantations with trees of the same species and of uniform size and age often create perfect conditions for the rapid spread of insects and diseases. Even the more complex uneven-aged forests with their inherent check-and-balance systems can develop devastating populations of pests. At this point the forester must consider direct control measures.

Because effective direct control of insects and diseases of standing timber is generally expensive, it is employed only when the potential mortality or loss in growth is extreme. Routine monitoring of insects and diseases allows foresters to schedule timely harvests of infested trees and to limit the spread of the problem to uninfested trees or areas. These sanitation and salvage harvests, coupled with piling and burning the limbs and branches left after logging, reduce the material and conditions that allow pest populations to develop. Traps baited with sex-attractant chemicals, or pheromones, are a promising method to reduce breeding populations of certain insects. Application of insecticidal or fungicidal sprays from the ground or from low-flying aircraft offer a short-term measure to check sudden plagues of insects or outbreaks of fungal diseases. Action has most frequently been taken against exceptional outbreaks of defoliating caterpillars, including those of the gypsy moth in the United States, the nun moth in central Europe, and the pine looper moth in England. At the time of year when feeding caterpillars are most vulnerable, light aircraft fly across the forest on carefully planned courses, distributing pesticides.

Control of defoliating caterpillars

A disadvantage of these blanket treatments by potent, broad-spectrum chemicals is that they also eliminate parasitic and predatory insects that serve as natural controls on the pest's numbers; they may also adversely affect birdlife. In practice, large-scale chemical treatments of forests are infrequent and are restricted to a small proportion of the areas at risk. Generally, natural control through predatory organisms, which also cycle opportunistically in a slightly delayed sequence with the pest populations, combined with physical factors like cold winters, provides adequate checks. Biological control involving the release of predators or diseases of pests is promising in some situations.

Less spectacular preventive measures are commonly taken as routine steps in practical forestry to lessen anticipated losses. Nursery stock, easily reached and handled, may be grown in fumigated seedbeds and sprayed during production so that uninfested and vigorous seedlings are planted in the forests. Prompt removal of logs from the forest to distant processing mills transfers beetles that may emerge from beneath the bark to areas where they can do no harm. Stumps of freshly felled conifers can be easily and cheaply treated by brushing on a fungicide to check the white root-rot fungus, *Fomes annosus*. This is a serious agent of decay that spreads underground through root grafts after gaining entry via the exposed surface of a felled stump.

Agroforestry. Agroforestry is a practice that has been utilized for many years, particularly in developing countries, and is now widely promoted as a land-use approach that yields both wood products and crops. Trees and crops may be grown together on the same tract of land in various patterns and cycles. The trees may be planted around the perimeter of a small farm to provide fuelwood and to serve as a windbreak. The limbs and foliage may be removed periodically for livestock fodder. Trees also may be planted in rows that alternate with crops or they may be planted more densely with interplanting of crops until crown closure of the trees precludes further crop production. These practices are most extensively used as a part of subsistence agriculture, but their use in large-scale production systems is becoming more common.

Urban forestry. Urban forestry, which is the management of publicly and privately owned trees in and adjacent to urban areas, has emerged as an important branch of forestry. Urban forests include many different environments such as city greenbelts; street and utility rights-of-way; forested watersheds of municipal reservoirs; and residential, commercial, and industrial property. An important distinction between urban and rural forestry is that urban trees are more highly valued than rural trees and often receive expensive individual care and attention. Many professional foresters are trained to handle the special problems of urban trees and to foster the diverse benefits they provide. (W.R.C./P.E.P./H.L.E.)

Wood production

Wood, botanically the principal strengthening and water-conducting tissue of stems and roots, is produced by many plants, including herbaceous ones, but wood valuable as a material, as considered in this article, derives mainly from the trunks of forest trees. As such, wood has been in service since humans appeared on Earth and has contributed to survival and to the development of civilization. In contemporary times, in spite of technological advancement and competition from metals, plastics, cement, and other materials, wood maintains a place in most of its traditional roles, and its serviceability is expanding through new uses with the result that its consumption is steadily increasing. The long list of present wood uses includes products in which its natural texture is retained and others in which the wood is mechanically and chemically modified to the extent that its presence cannot be recognized. In addition to well-known products, such as lumber, furniture, and plywood, wood is the raw material for wood-based panels, for pulp and paper, and many other products, especially chemical derivatives of cellulose and lignin. Finally, wood is still an important fuel in much of the world.

The versatility of wood is basically attributable to its structure, chemical composition, and properties. Produced by many botanical species, it is available in various colours and grain patterns. In relation to its weight, wood has high strength. It is insulating to heat and electricity and has desirable acoustical properties. Further, wood imparts a feeling of "warmth" not possessed by competing materials, such as metals, and is relatively easily worked. Cellulose is mostly obtained from wood. Wood is found throughout the world and is a renewable resource—in contrast to coal, ores, and petroleum, which are gradually exhausted. Wood has certain undesirable characteristics, however. It may burn and decay. It is hygroscopic (moisture absorbing), and in gaining or losing moisture it changes dimensions. As a biological product, wood is variable in quality.

STRUCTURE OF WOOD

Growth rings

General xylem structure and cell types. Examination of a stump or the cross section of a tree trunk reveals a series of successive growth layers of wood that surround a small central pith and are protected by a layer of bark. Between the bark and the wood is a narrow sheath of tissue called the vascular cambium. This lateral meristem is indistinguishable with the naked eye and produces all the cells that develop into xylem, or wood. In the temperate zones each growth ring of wood may be a product of one year's growth, but various environmental conditions may induce in each year the formation of more than one growth layer or discontinuous growth layers. In tropical areas growth rings are formed in response to wet and dry periods or other environmental cues. For these reasons, the term growth ring is preferred over annual ring.

Earlywood and latewood. Growth rings are visible because of distinct boundaries that result from the transition of earlywood to latewood. Earlywood cells are produced by the cambium early in the growth period and are typically less dense than the latewood cells because wider cells with thinner walls predominate in the earlywood (Figure 4). The latewood forms a distinct boundary between growth rings because of its sharp contrast to the earlywood of the following season. The transition from earlywood to latewood in the same growth ring is more or less gradual. The relative amounts of early- and latewood are affected by environmental conditions and differences in tree species. The proportion of early- and latewood affects the physical properties of wood and hence is an important concern related to utilization of wood derived from intensively managed tree plantations where growth conditions are altered.

Sapwood and heartwood. The sapwood is the portion of the xylem that stores food produced in photosynthesis and conducts water and dissolved nutrients to the crown of a tree. As a tree ages, the earlier produced growth rings of xylem usually become nonfunctional and develop into heartwood. Formation of heartwood involves the accumu-

lation of metabolic by-products that may be inhibitory or even toxic to living cells. Movement of these substances occurs along the rays toward the centre of the tree where they eventually result in the death of living cells. Although sometimes pale, heartwood is generally darker in colour than the sapwood and is often preferred for many uses because the gums and resins deposited in the cell cavities and spaces between cells impart resistance to insects and decay, and they give the wood a rich colour.

Vascular rays

Transverse, radial, and tangential sections. Examination of a block of wood with the aid of low magnification reveals two distinct systems of cells. The axial system contains files of cells with their long axes oriented vertically in the stem, while the radial system comprises files of cells oriented horizontally with respect to the stem axis. Each of the two systems has its characteristic appearance in the three kinds of sections employed in the study of wood: transverse, radial, or tangential. The transverse, or cross section, cuts at right angles to the main axis of the tree to reveal the smallest dimension of cells in the axial system. The radiating pattern of vascular rays across growth rings is exposed. When a tree is cut lengthwise, either radial or tangential sections are obtained. Both show the vertical extent of cells of the axial system, but they give different views of the rays. The radial section passes through the pith and exposes the rays as horizontal bands lying across the axial system. Growth rings appear as parallel bands. A tangential section cuts at a tangent to the growth rings and cuts rays perpendicular to their horizontal extent to reveal the height and width. Growth ring arrangement is paraboloid in appearance. This occurs because the wood is cut at an angle due to the slight taper of the tree trunk. The different structural aspects of wood revealed in these respective sections accounts for the various grains or patterns seen in sawn lumber.

Cell types. Wood is a composite of tiny cells. Indicative of their small size is the estimate that one cubic metre of spruce wood contains 350,000,000,000–500,000,000,000 cells. Differences in cell form and arrangement account for an anatomy unique to each tree species. The principal cell types of wood are tracheids, vessel members, fibres, and parenchyma. Most cells are tubelike and are arranged parallel to the axis of the trunk. The tracheid is a primitive cell type with closed ends.

Evolutionary development of the xylem followed two lines that enhanced efficiency of conduction through development of vessel members and structural support through development of fibres. Both of these types of cells evolved from tracheids. Vessel members present wide variation in length, from 0.3 to 1.3 millimetres. Diameters range, in general, from about 0.01 to 0.5 millimetres. Pits in the sidewalls of vessel members generally are smaller than those in tracheids, but their function in translocation of water in the xylem is limited because of the large perforations in the end walls. Obstructions in vessel members called tyloses may occur and are frequent in heartwood. Fibres, too, are shorter than tracheids (one to two millimetres on the average) and have narrow diameters, closed ends, and thick walls. Cells with characteristics of more than one type of the basic cells occur in wood and are known as vascular tracheids, fibre tracheids, and libriform fibres.

Parenchyma cells are the simplest cell type in wood. They are blocklike and very small (0.1–0.2 millimetres in length). The epithelial cells that line resin canals and gum ducts are specialized parenchyma cells. Almost all wood cells in living trees are dead. Their protoplasmic contents have disintegrated, but the rigid cell walls remain around the cell cavities. The exceptions are a few rows of young cells next to the cambium that are produced during current growth and have not completed development and parenchyma cells located in the sapwood.

Structural variations and defects. The cellular composition and arrangement of wood varies among species. This influences appearance and properties and makes for a wide choice of woods for various uses. It also is the basis for wood identification. Woods of gymnosperm species, such as pine and spruce, are known as softwoods, whereas those of broad-leaved angiosperm species, such as oak and beech, are hardwoods. However, the implied distinction is not true; some hardwoods (*e.g.*, balsa) are softer than some softwoods (*e.g.*, yew).

Porous and nonporous wood

In terms of wood anatomy, trees are placed in two general categories—porous or nonporous. With only rare exceptions these anatomical categories correspond to the taxonomic classification of trees. Gymnosperms are nonporous and angiosperms are porous. Gymnosperm wood is relatively simple in structure. Its most striking feature is the absence of vessels and hence the name nonporous. The wood consists primarily of tracheids and fibres in the axial system. Axial parenchyma and resin canals are present in certain species, but radial parenchyma is always present and constitutes the rays, sometimes together with

radial tracheids (Figure 5A). The wood of angiosperm trees consists of vessels, tracheids, fibres, and parenchyma in various proportions. All four cell types occur in the axial system. The size and distribution of vessels allows for further classification as ring-porous and diffuse-porous woods. Ring-porous trees such as oak and ash have distinct vessels of larger diameter in the earlywood, whereas diffuse-porous trees such as birch and maple have vessels of about the same size uniformly distributed throughout a growth ring (Figure 5B,C). Parenchyma cells and occasionally tracheids constitute the radial system.

Variation in wood is caused by the presence of defects such as knots, spiral grain, compression and tension wood, shakes, and pitch pockets. Knots are caused by inclusion of dead or living branches as a tree grows in circumference. Spiral grain is the spiral arrangement of cell elements with regard to tree axis. Compression and tension wood are structural abnormalities in gymnosperms and angiosperms, respectively, that form when trees deviate from the normal, vertical position because of wind or other loads. Shakes are separations of wood tissue, and pitch pockets are separations filled with resin. Defects, according to kind and extent, may adversely affect the appearance, strength, dimensional stability, and other properties of wood.

Ultrastructure and chemical composition. Polarization microscopy, X rays, electron microscopy, and other techniques provide information regarding the structure of cell walls and other features hidden to light microscopes. Cell walls are crystalline. They are composed of a thin primary wall and a much thicker secondary wall, the latter made of three layers. The smallest visible building units of cell wall are the fibrils, which appear stringlike under the electron microscope. The orientation and weaving of microfibrils varies, which makes possible the distinction of layers. The secondary wall is absent in pit areas, and the primary wall, consisting of randomly and loosely arranged fibrils, forms the pit membrane. In tracheids of gymnosperms, the pit membrane possesses a central thickening, the torus.

The principal compound in cell walls is cellulose. Its molecules are linear chains of glucose, which may reach four microns in length. Orderly arrangement of cellulose molecules in fibrils (micelles) accounts for its crystalline properties. Noncellulosic constituents (hemicelluloses, lignin, and pectins) encrust the matrix among fibrils. Some hemicelluloses appear to serve as an important cross-link between the noncellulosic polymers and cellulose. Lignin is a complex substance that imparts rigidity to cell walls. Pectins are important constituents of the layer between cell walls (middle lamella).

Cellulose and the other chemical constituents are contained in wood in the following proportions (in percent of the oven-dry weight of wood): cellulose 40–45 percent (about the same in gymnosperms and dicotyledonous angiosperms); hemicelluloses 20 percent in gymnosperms and 15–35 percent in angiosperms; lignin 25–35 percent in gymnosperms and 17–25 percent in angiosperms; and pectic substances in very small proportion. In addition, wood contains extractives (gums, fats, resins, waxes, sugars, oils, starches, alkaloids, tannins) in various amounts (usually 1–10 percent, sometimes 30 percent or more). Extractives are not structural components but are deposited in cell cavities and intercellular spaces and may be removed (extracted) without change of wood structure.

Extractives

WOOD PROPERTIES

Density and specific gravity. Density is the weight or mass of a unit volume of wood, and specific gravity is the ratio of the density of wood to that of water. In the metric system, density and specific gravity are numerically identical; *e.g.*, the average density of the wood of Douglas fir is 0.45 grams per cubic centimetre (28 pounds per cubic foot) and its specific gravity 0.45, because one cubic centimetre of water weighs one gram. The density of wood varies from about 0.1 to 1.2 grams per cubic centimetre (specific gravity 0.1 to 1.2; Table 2). Differences between species and among samples of the same species are attributable to different proportions of wood substance, void volume (volume of cell lumens and wall spaces), and the content of extractives. The amount of extractives in wood varies from less than 3 percent to more than 30 percent of the oven-dry weight. It is obvious that the presence of these materials, located to a large extent within the cell wall, can have a major effect upon the density.

Determination of the density of wood in relation to that of other materials is difficult because wood is hygroscopic, and both its weight and volume are greatly influenced by moisture content. In order to obtain comparable figures, weight and volume are determined at specified moisture contents. The standards are oven-dry weight (practically zero moisture content) and either oven-dry or green volume (moisture content above fibre saturation point, which averages about 30 percent).

Green volume

Most mechanical properties of wood are closely correlated to density and specific gravity. It is possible to learn more about the nature of a wood sample by determining its specific gravity than by any other simple measurement.

Hygroscopicity. Wood is hygroscopic (*i.e.*, exhibits an affinity for water) and can absorb water as a liquid, if in contact with it, or in the form of vapour from the surrounding atmosphere. Though wood may absorb other liquids and gases, water is the most important. Because of its hygroscopicity, wood, either as a part of the living tree or as a material, always contains moisture. (Water and

Source: Adapted from Kollmann, *Technologie des Holzes und der Holzwerkstoffe* (1951).

moisture are used here without distinction.) This moisture affects all wood properties, but it should be noted that only moisture contained in cell walls is important; moisture in the cavities merely adds weight.

The amount of moisture held in cell walls varies from about 20 to 35 percent (on the basis of oven-dry weight of wood). The theoretical point at which cell walls are completely saturated and cell cavities empty is known as the fibre saturation point. Beyond this point, moisture goes into the cavities, and when these are completely filled, the maximum moisture content of the wood is reached. Moisture content of some woods can be high. Very light woods, such as balsa, can hold up to about 800 percent, pine 250 percent, beech 120 percent, and so on.

When green wood is exposed to the atmosphere, its moisture content gradually decreases. Moisture in the cell cavities is lost first. In time the moisture content of wood falls to levels ranging (for localities in the temperate zones) from about 6 to 25 percent (average 12–15 percent). Local conditions of air temperature and relative humidity dictate the final moisture level.

Hygroscopicity is of primary importance because moisture in wood affects all wood properties. It has a direct relation to weight of logs and green lumber, with consequent influence on transportation costs. Dimensions change, as explained below (see *Shrinkage and swelling*). Resistance to decay and insects is greatly affected. Also influenced is processing, such as drying, preservative treatment, and pulping. Gluing and finishing and the mechanical, thermal, and acoustical properties of wood are all affected by its moisture content.

Shrinkage and swelling. Wood is subject to dimensional changes when its moisture fluctuates below the fibre saturation point. Shrinkage of the cell wall, and therefore of the entire wood, occurs as moisture escapes from between long-chain cellulose and hemicellulose molecules. These molecules can then move closer together. The amount of shrinkage that occurs is generally proportional to the amount of water removed from the cell wall. Swelling is simply the reverse of this process. It is characteristic that dimensional changes are anisotropic; *i.e.*, different in axial, radial, and tangential directions. Average values for shrinkage are roughly 0.2 percent, 4 percent, and 8 percent, respectively. Volumetric shrinkage averages 12 percent (Table 2). These values refer to changes from green to oven-dry conditions and are expressed in percent of green dimensions. The negligible longitudinal shrinkage of normal wood is one of the characteristics that makes lumber and lumber products such usable building materials. The factors, in addition to moisture content, that affect shrinkage and swelling are density (specific gravity), extractives, mechanical stresses, and abnormalities in wood structure.

Dimensional changes in wood caused by shrinkage and swelling may result in change of shape, checking (formation of cracks), warping, case hardening (release of stresses in resawing or other machining that causes warping), honeycombing, and collapse. Thus, the fact that wood shrinks and swells constitutes a great obstacle to its utilization. Several methods are used to improve the dimensional stability of wood, including resin impregnation to replace water in cell walls and treatment with various chemicals to eliminate the binding sites for water molecules. Though suitable for some commercial use, these are sufficiently expensive to limit their application to specialty items. Large-scale dimensional stabilization is accomplished by special wood construction. Plywood, discussed below, is an example.

Dimensional stabilization techniques

Mechanical properties. The mechanical or strength properties of wood measure its ability to resist applied forces that might tend to change its shape and size. Resistance to such forces depends on the magnitude and manner of application of the force. It also depends on various characteristics of the wood, such as moisture content and density. The term strength is often used in a general sense to refer to all mechanical properties. This can lead to confusion since there are many different types of strength and elastic properties. A wood that is relatively strong with respect to one strength property may rank lower in a different property when compared to another species. It is also important to note that wood has drastically different strength properties parallel to the grain than it does across the grain—*i.e.*, is anisotropic.

The mechanical properties of wood include strength in tension and compression (axial and transverse), shear, cleavage, hardness, static bending, and shock (impact bending, toughness). Respective tests determine stresses per unit of loaded area (at elastic limit and maximum load) and other criteria of strength, such as modulus of elasticity (a criterion of stiffness), modulus of rupture (bending strength), elastic resilience, and toughness. Tests are normally conducted with small, clear specimens, usually two by two inches or two by two centimetres in cross section. Laboratory data are analyzed to produce working stresses, which are available for use by engineers and architects in designing wooden structures. Mechanical properties of woods of several tree species are given in Table 2. Tests are sometimes conducted with structural components of actual size. Individual cells (tracheids, fibres) are also subject to testing since their strength is related to the strength of products (*e.g.*, paper).

Density is the best index of the strength of clear wood; higher density indicates greater strength. The strength of wood is also influenced by its moisture content when it fluctuates below the fibre saturation point. Generally, a decrease in moisture content is accompanied by an increase in most strength properties. Temperature and duration of loading also affect strength. In general, strength falls as temperature rises. Wood loaded permanently will support smaller loads than those indicated by a short-time test in the laboratory. The most important strength-reducing factors are wood defects, such as knots, abnormal anatomy resulting from compression and tension, and grain deviations. Their adverse effect depends on the kind and extent of the defect, position, and manner of loading.

Lumber grading

Defects constitute the basis for visual grading rules of lumber and other wood products. The rules for grading hardwood lumber are different than those for softwoods. Hardwood lumber grades were developed with the assumption that the lumber would be cut into smaller pieces for the manufacture of furniture or millwork parts. Grading is based upon the percentage of the board that is usable in smaller clear pieces free of defect on one or both sides. The regular hardwood lumber grades are thus not readily adaptable to applications where the entire board will be used as a single piece.

Softwood lumber grades, in contrast, are based principally on structural uses for which the strength or appearance of the entire board is important. Grades are usually assigned by a lumber grader, who must make a rapid judgment about the strength-reducing defects present in each piece. Most structural lumber is graded in this way. Grading leads to more efficient utilization of wood and is essential in order to achieve adequate standards of safety in wooden structures.

Thermal properties. Although wood expands and contracts with varying temperature, these dimensional changes are small in comparison to the shrinkage and swelling caused by variation of moisture content. In most cases expansion and contraction are negligible and without practical importance; only temperatures below 0° C (32° F) may cause surface checks, and in living trees, unequal contraction of outer and inner layers may result in frost cracks. Such low thermal expansion and contraction, in conjunction with low heat conductivity, constitute advantages of wood when it is exposed to fire. In addition, the low heat conductivity of wood (high insulating value) makes it desirable for building construction. Heat conductivity is about two to two and a half times greater axially than transversely and increases with density and moisture content.

Exposed to high temperatures, wood burns; at a temperature of about 400° C (752° F) wood ignites easily because of the production of flammable gases. The heating value of one kilogram of dry wood is about 4,000–5,000 kilocalories. Differences among species derive from differences in density and the presence of extractives (*e.g.*, resin in pines).

Electrical properties. Very dry, especially oven-dry, wood constitutes an excellent insulator. As moisture content increases, however, electric conductivity increases; and the behaviour of saturated wood approaches that of water. Noteworthy is the spectacular decrease of electric resistance when moisture content increases from zero to fibre saturation point. Within this range, electric resistance decreases about 10,000,000 times, whereas from fibre saturation point to maximum moisture content it decreases only about 50 times or less. Other factors, such as species and density, have little effect on the electric resistance of wood.

Dielectric property of wood

Important also is the dielectric property of wood. Wood is a nonconductor of electricity but will sustain the force of an electric field passing through it. This property, expressed in dielectric constant and power factor, assumes a practical importance with wood in drying, gluing (with high-frequency electric current), or making electrical meters (capacity and radio-frequency power-loss type) for measuring its moisture content.

Wood exhibits the piezoelectric effect; *i.e.*, electric polarization occurs under mechanical stress and also mechanical strain in an electric field.

Acoustic properties. Wood can produce sound (by direct striking) and can amplify or absorb sound waves originated from other bodies. For these reasons, it is a unique material for musical instruments and other acoustic purposes. The pitch of sound produced depends on the frequency of vibration and the dimensions, density, moisture content, and modulus of elasticity of the wood. Larger dimensions, lower moisture content, and higher density and elasticity produce sounds of higher pitch (more acute in tone). Sound waves originating from other bodies and striking wood are partly absorbed and partly reflected; wood is also set in vibration. The sound may be amplified, as in violins, guitars, organ pipes, and other musical instruments, or absorbed, as in wooden partitions. Normally, wood absorbs only a small portion of acoustic energy (3–5 percent), but special constructions with empty spaces and porous insulation boards may increase this capacity up to 90 percent. The velocity of sound in wood is high (3,500–5,000 metres per second axially and 1,000–1,500 metres per second transversely). Defects such as decay affect acoustic properties; use of this fact is made in nondestructive testing of wood.

HARVESTING THE WOOD CROP

A prerequisite to harvest is a management plan, which determines the yearly yield and the method of removal. The harvest method chosen can involve clear-cutting large areas or selective cutting of individual trees or groups of trees. For a forest harvested under the sustained-yield concept the volume of timber removed at periodic time intervals is dependent on the net growth of all trees during that interval. This concept, combined with natural and artificial seeding and planting, ensures a continuous production of wood and conservation of forests. The season of harvest is not determined by the time of ripening, as with agricultural crops, but by such factors as the conditions of work for personnel, machines and animals, and the danger of damage to the remaining forest and to the harvested wood. Because felled trees are vulnerable to attack by fungi and insects, the harvest is timed to avoid conditions favourable for these organisms.

Harvesting includes felling, bucking (cross-cutting into logs), limbing, debarking, and skidding (*i.e.*, moving the logs from the felling location) to the roadside or concentration yard, from where the logs are transported to industries. Felling is commonly accomplished by chain saw; the ax and handsaw are little used today. The chain saw is also used for bucking and in most cases for limbing. Bucking is not always done at the felling site. Sometimes whole trees are skidded to a concentration yard for further processing. Debarking is sometimes done in the forest by ax or spud (a combination spade and chisel) or by portable mechanical debarkers, and sometimes in factories by stationary mechanical debarkers or water jets. Special equipment has been developed for harvesting pulpwood (Figure 8). An example is a combine harvester equipped with giant scissors, which shear the tree at the base. It is then lifted to a carriage and drawn through a trimmer, which strips off the branches. Another blade bucks the trunk into logs, which fall into an attached cradle. Sometimes the entire tree, including its branches, is chipped in the woods. The chips are blown directly into a truck or are carried by pipeline to a pulp mill.

Pulpwood harvesting

Skidding is done by tractors or by animals; in various forests of the world, horses, mules, oxen, and elephants are employed. Tractors are usually employed in combination with steel cables, and the logs are skidded on the ground or lifted partially or wholly off the ground. In the northwest United States tall trees, 80–100 metres high, are topped by a climbing logger and are employed as masts, or spar trees, to attach cables for skidding. In rare cases where slopes are steep and erosive, helicopters or giant balloons are used. In general, mechanization of harvesting operations is the trend, but regions of small annual yield and unfavourable topography restrict the potential of expensive machines, and in many countries human and animal labour is still commonly used.

The main source of usable wood is the tree trunk. Tree tops and heavy branches are cut into short lengths for cordwood and stacked wood, or they are chipped. Stumps, which should be as low as possible, roots, logging residues, and bark, if logs are debarked, remain in the forest. Machines also have been designed to extract the roots of the trees. This technique is employed to some degree in the coniferous forests of the southeastern United States.

WOOD UTILIZATION

This section is concerned with the main products of primary processing of wood, and related treatments, such as drying and preservation, that ensure its better performance in use. Some of these products, such as poles, posts, and railroad ties, are used directly, but most constitute intermediate materials that by further processing are manufactured into final products or structures.

Roundwood products. Poles, posts, and certain mine timbers are products in round form. Poles are used in telecommunication lines (telegraph, telephone) or as pilings (*i.e.*, foundations for wharves or buildings), and posts in fences, highway guards, and various supports. As a rule, these products are subjected to preservative treatment. The bark is removed in the forest or factory.

Sawn wood. Lumber is the main sawn-wood product. Lumber of large dimensions (more than about 10 centimetres in width and thickness) suitable for heavy constructions is called timber. This term, however, is also loosely applied to wood of a forest stand and to products of round form. Another important product made by sawing, and sometimes by hewing, is railroad ties.

Processing logs into lumber

Lumber is usually the product of the sawmill and is produced in varying sizes (usual, approximate dimensions: thickness two to 10 centimetres, width eight centimetres and over, length two to six metres). Conversion of logs to lumber involves breakdown into boards of various thicknesses, resawing, ripping, and crosscutting. The organization of production varies by manufacturing plants, but a generalized scheme is as follows. Logs, transported from the forest, are stored in water, usually a pond or river, or in a ground storage yard. If a long ground-storage time is anticipated, the logs are kept under a constant water mist. Each log enters the mill on a conveyor; in large operations it is mechanically debarked and in some is crosscut to length. Supported on a carriage, it is brought to a headsaw, which may be of three types: band saw, gang saw, or circular saw. A band saw consists of an endless band of steel, equipped with teeth usually on one edge only and moving around two wheels—one powered and the other free-running. Gang saws commonly consist of a reciprocating (vertical or horizontal) frame in which a number of saw blades are mounted at predetermined lateral distances. A circular saw consists of a circular blade having teeth (sometimes removable) on its periphery and mounted on a shaft. Band and gang saws have relatively thin blades and are therefore less wasteful than circular saws; band and circular saws permit changing board thickness and turning of the log after each cut; therefore, breakdown is more advantageous in terms of yield and grade. In general, and except for logs of very large diameter, gang saws are extensively used, especially in Europe, as headsaws for softwoods, and band saws are used for hardwoods.

Breakdown is accomplished in one or more operations by the use of one, two, or more machines in combination; *e.g.*, if two gang saws are used, the first saw removes slabs (the outside pieces cut from a log) and, in certain cases, some boards. The piece produced is then turned 90° and introduced into the second saw, which converts it to boards. The second operation may be considered resawing; in general, resawing consists of either dividing thick boards into thinner ones or producing boards from slabs. Ripping, or edging, is the removal of wane or bark from the sides of boards by passing them through a band saw or a machine that has two small circular saw blades mounted on a shaft; one is stationary and the other may move sidewise, thus setting board width. Finally, certain boards are crosscut to square their ends and remove defects. Modern sawmills are controlled with the aid of computers and other types of electronic equipment.

Drying. Drying is an essential preparation of lumber and wood. Proper drying reduces the magnitude of dimensional changes due to shrinkage and swelling, protects wood from microorganisms, reduces weight and transportation costs, prepares wood better for most finishing and preservation methods, and increases its strength. Drying is accomplished in the open air or in kilns. Other special methods of drying also exist.

The air-drying yard

The air-drying yard is located close to the lumber plant on a dry site, where air movement is not obstructed by tall trees or buildings. The ground surface is kept free from debris and vegetation. The time required to air dry from green to 20 percent moisture content varies in general from about 20 to 300 days for material 2.5 centimetres thick, depending on species, place, and time of the year.

Air drying can be accelerated by means of fans, the application of "solar heat," and "predriers" (fans and low-temperature heating). With beech, walnut, and some other woods, steaming is also employed before air drying; this reduces drying time by increasing the rate of drying and at the same time darkens the wood and makes it more desirable for use as furniture.

Kiln-drying is conducted in a closed chamber, under artificially induced and controlled conditions of temperature, relative humidity, and air circulation. This method permits much faster reduction of moisture content to levels independent of weather conditions: reduction of moisture from 20 to 6 percent is accomplished in two to 15 days, and from green to 6 percent in two to 50 days for material 2.5 centimetres thick. The source of heat is usually steam circulating in pipe coils. Relative humidity is controlled by allowing steam to enter the chamber through a perforated pipe; such control is necessary in order to regulate the exit of moisture and avoid defects such as checking (cracking or splitting). In order to obtain satisfactory results air movement is necessary to carry the heat from its source to the lumber and to carry away the evaporated moisture; air circulation is produced by means of fans located within the kiln, and sometimes by blowers placed outside. Kiln-drying normally involves temperatures below 100° C (212° F), usually in the range 40°–75° C (104°–167° F). Such temperatures are high enough to kill insects, which is another advantage of kiln-drying over air drying.

In addition, wood may be dried by special methods that include the use of solvents, vapours, and chemicals and high-temperature drying, boiling in oily liquids, vacuum drying, electric drying, and drying by infrared radiation. The last three methods are expensive and therefore not commercially applicable.

Fungi

Preservation. Wood is subject to deterioration by fungi (causing stain and decay), insects, marine organisms, fire, and other destructive agents. By far the most important cause of wood loss is decay. Wood decays if the conditions are suitable for the growth and activity of fungi. Such conditions include favourable moisture, air, and temperature. A moisture content below 20 percent inhibits growth of fungi. If wood is kept under water, it also cannot be attacked because of the lack of sufficient available oxygen. There are many examples of wooden structures lasting hundreds or even thousands of years; *e.g.*, in the tombs of pharaohs. Under conditions favourable for fungi (for example, when wood is used in contact with soil) no wood is immune, although some species do better than others. The durability of exposed timber, such as railroad ties or mine timbers, can be greatly increased by impregnation with toxic chemicals. The application of preservatives is accomplished by brushing, spraying, dipping, steeping, hot and cold bath, and diffusion, but impregnation under pressure is the most efficient. This requires special installations such as treating cylinders (up to 50 metres in length and three metres in diameter, storage tanks, pumps, a boiler plant (for steam production), and other auxiliary equipment.

Veneer. Veneer is a thin layer, or sheet, of wood that is uniform in thickness—commonly about 0.6–eight millimetres. According to the method of production (see Figure 6), it is classified into rotary cut (cut in a lathe by rotating a log against a knife, similar to peeling), sliced (cut sheet by sheet from a log section or "flitch"), and sawn (produced by sawing with a special tapered saw). More than 90 percent of all veneer is rotary cut, but figured woods producing veneer for furniture and other decorative purposes are sliced; sawn veneer is seldom produced because it is a wasteful operation.

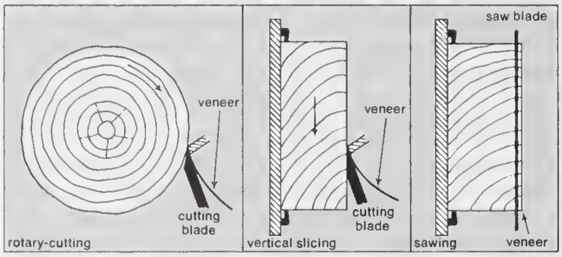

Figure 6: Methods of veneer production.

Veneers are used primarily for plywood and furniture, but they are also used in toys, containers of various kinds, matches, battery separations, and other products. An experimental product related to veneer is slice wood; this is thicker, and its production is less wasteful than lumber of the same thickness.

Plywood and laminated constructions. Plywood and laminated constructions are glued-wood products. Although gluing is an old art, practiced since ancient times, the modern development of various products was made possible by the improvement of glues—especially by the production of synthetic resin adhesives.

Manufacturing plywood

Plywood is a panel product manufactured by gluing together one or more veneers to both sides of a veneer, solid wood, or reconstituted wood core (see Figure 7). In the case of solid-wood-core plywood and reconstituted-wood-core plywood, an additional intermediate step is the production of cores, which are made by lateral gluing of blocks or strips of wood or by gluing oriented wood chips or flakes with resin adhesives.

In plywood the grain of alternate layers is crossed, in general at right angles; species, thickness, and grain direction of each layer are matched with those of their opposite number on the other side of the core; usually the total number of layers is odd (three, five, or more). Thus assembled, the panels are brought to presses for gluing with either natural (animal, casein, soybean, starch) or synthetic resins, such as phenol- or urea-formaldehyde. Certain synthetic resins, such as phenol-formaldehyde, properly used, may produce joints more durable than the natural wood itself—highly resistant to weather, microorganisms, cold, hot and boiling water, and steam and dry heat; such plywood is known as exterior plywood (in contrast to interior).

Plywood has many advantages over natural wood, an important one being greater dimensional stability. Its uniformity of strength, resistance to splitting, panel form, and decorative value make it adaptable to various uses. In addition to flat panels, plywood is manufactured in curved form (molded plywood), used for boats, furniture, and many other products; this is done by bending and gluing veneer sheets in one operation—by use of curved forms in

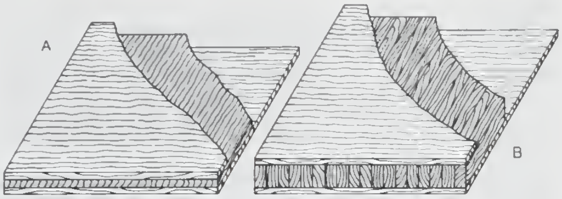

Figure 7: *Types of plywood.*
(A) Three-ply all-veneer. (B) Three-ply solid wood core (laminboard).

a press or by fluid pressure applied with a flexible "bag" or "blanket" of an impermeable material.

Another important glued product is laminated wood. This is produced mainly from lumber with the grain of all boards parallel to one another. The product is used in beams, columns, and arches for buildings, boat keels, aircraft carrier decking, minesweepers, and helicopter propellers. In curved products, production involves simultaneous bending and gluing. Laminated wood possesses several advantages over solid wood. Large members of various sizes and shapes impossible to make from solid wood can be fabricated; the individual boards used, due to their relatively small thickness, may be properly dried without checking, and defects, such as knots, may be removed; structures may be designed on the basis of required strength, and wood of low grade can be positioned accordingly; gluing permits utilization of small dimensions.

"Improved wood"

Special products are made of veneer sheets that are impregnated with synthetic resin, assembled parallel or in the conventional plywood manner, then pressed and glued. This results in "improved wood," characterized by high density; improved dimensional stability, strength, and appearance; and resistance to fungi, insects, fire, and weathering. Finally, veneer and plywood are fabricated into sandwich constructions by gluing in combination with other materials, such as fibreboard, paper, cloth, asbestos, metal, and plastics.

Particle board. This panel product is manufactured of particles of wood glued together. Particles are flakes, shavings, or splinters produced by cutting or breaking. Boards are produced either with the same particle geometry throughout or in layers—with different particle patterns on the faces and in the core.

Particle board production is a relatively new industrial development, begun in the early 1940s and rapidly expanding since in all countries. It was made possible by the development of synthetic resins and has greatly contributed to better wood utilization by permitting the use of residues of other wood-using industries and of harvesting operations in forests. Debarking is not always necessary.

Fibreboard. This panel product is made of fibres of wood. As in the case of particle board, unbarked wood of low quality may be utilized through pulp preparation, sheet formation, pressing, and finishing treatment. Pulping is usually mechanical or semichemical, but a so-called explosion process is also used, in which chips are subjected to high-temperature steam in a "gun" or high-pressure vessel; ejected through a quick-opening valve, they are reduced to pulp. Two basic processes—wet felting and air felting—are employed in sheet formation. Before entering into sheet formation, certain materials are added to the pulp to improve water resistance, strength, and other properties. In wet felting, glue (synthetic resin) is usually not used, though in the dry process it is added in a proportion of 1–4 percent (on the basis of dry fibre mass). Other additives, such as rosin, paraffin, wax, and chemicals, are used to increase resistance to microorganisms, insects, and fire. Air felting offers advantages with regard to water consumption and pollution and, for this reason, is preferred over the wet process. Air felting produces either semidry wood (12–45 percent moisture content) or dry wood (8–10 percent).

In general, panel products (plywood, particle, and fibreboard) serve a wide range of uses: building construction, including walls, floors, roofs, and doors; exterior siding, interior finishing (*e.g.*, wall paneling), and shelves; furniture; shipbuilding; automobile manufacture; refrigeration cars; toys; concrete formwork; and many others. Special types combine decorative value with thermal- and sound-conditioning properties.

Pulping processes

Pulp and paper. Wood is the main source of pulp and paper. Preliminary production steps are debarking and chipping. Pulping processes are of three principal types: mechanical, or grinding; chemical, or cooking with chemicals added; and semichemical, a combination of heat or chemical pretreatment with subsequent mechanical reduction. The yield of pulp ranges from about 40 percent by chemical methods to 95 percent by mechanical ones. Chemical processes are based on either acids (sulfite pulping) or alkalies (alkaline pulping, including the soda and the sulfate process). The pulp produced is washed, screened, thickened by the removal of most water, and bleached. Paper manufacture involves beating the pulp, loading, introducing various additives, refining, and running the pulp into the paper machine (see INDUSTRIES, CHEMICAL PROCESS: *Papermaking*).

Other products. The total number of products made of wood and its derivatives (*e.g.*, cellulose) is enormous, according to some estimates as high as 10,000.

Mechanically derived products. In addition to those already mentioned, some of the principal applications of wood include agricultural tools, aircraft, artificial limbs, barrels, baseball bats, baskets, blackboards, blinds (Venetian), bobbins, bowling pins, brush blocks, caskets, clothespins, crates, dowels, excelsior (wood-wool), fishing rods, golf clubs, gun stocks, handles, ice-cream spoons, insulating pins, ironing boards, ladders, novelties, oars, pallets, patterns and models, parquet flooring, paving blocks, pencils, picture frames, rules, scaffolding, scientific instruments, shingles, shoe lasts, skis, sleighs, smoking pipes, spools, tanks, tennis rackets, tongue depressors, toothpicks, vats, wood flour, and many others.

Chemically derived products. These include acetic acid, acetone, cellophane, cellulose acetate, charcoal, dyestuffs, ethyl alcohol, explosives, furfural, lacquer, methanol, molasses, oils, paper products, photographic films, pitch, plastics, rayon, rosin, sugars, synthetic sponges, tannins, tar, turpentine, vanillin, yeast, and many others. Promising developments include ablative carbon composite, a substance resistant to very high temperatures (2,800° C [5,072° F]); structural graphite composite—stronger, lighter, and more rigid than advanced metal alloys, suitable for airplane construction; and permanently fire-retarding rayon. The list of chemicals that can theoretically be produced from wood is a long one indeed and not materially different in length and contents from the list of products that can be made from petroleum.

The use of wood for fuel is diminishing in industrialized countries because of the increased use of petroleum; gas; electricity generated by solar, wind, atomic, and water

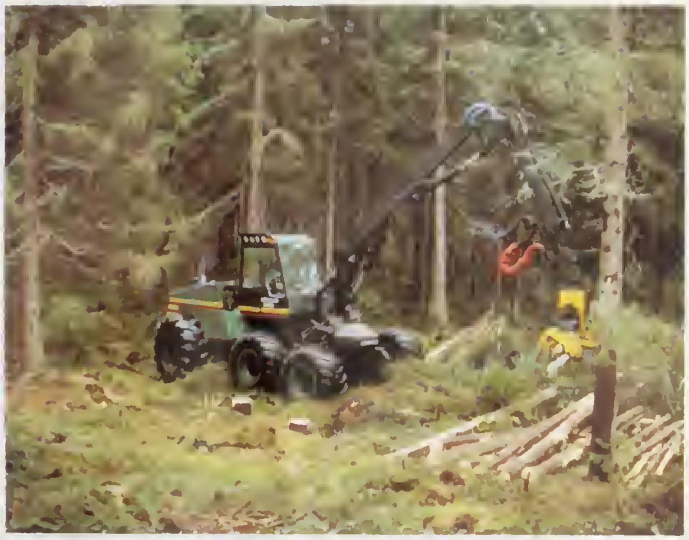

Figure 8: Single grip harvester at work in a tree plantation in Finland.

power; and coal. During periods of petroleum shortages wood is used for home heating, for generation of electricity via direct combustion, in the production of ethanol, and as a mixture with high-sulfur coal. Some countries are dependent on wood as the primary or sole source of fuel for cooking and heating. The production of fuelwood (from large coppice and low-quality forests) is essential to the survival of vast numbers of people, yet the problem of wood shortages is becoming more acute; this contributes to more complete utilization, which in turn depletes the existing wood resource and its potential for regeneration.

In addition to wood, increased attention is being focused on bark, which constitutes 10–15 percent of a tree volume. Bark is used in charcoal, as cork, in fibreboard (in mixture with wood), for soil improvement, and as a source of tannins and other chemicals. But further possibilities are recognized, particularly with respect to its chemical utilization. (G.Ts./W.R.C./P.E.P.)

BIBLIOGRAPHY

Forestry: Forestry textbooks usually deal with a specialized aspect of the science, often in one geographic region. WILLIAM M. HARLOW, ELLWOOD S. HARRAR, and FRED M. WHITE, *Textbook of Dendrology, Covering Important Forest Trees of the United States and Canada,* 6th ed. (1979), provides descriptions of major tree species in the region. Forest ecology is the subject of K.A. LONGMAN and J. JENÍK, *Tropical Forest and Its Environment,* 2nd ed. (1987); J.J. LANDSBERG, *Physiological Ecology of Forest Production* (1986); and HERMAN H. SHUGART, *A Theory of Forest Dynamics: The Ecological Implications of Forest Succession Models* (1984). For a general historical overview of forestry and related fields, see RICHARD C. DAVIS (ed.), *Encyclopedia of American Forest and Conservation History,* 2 vol. (1983).

Principles of forest management, worldwide in application, are systematically outlined by WILLIAM A. LEUSCHNER, *Introduction to Forest Resource Management* (1984); and JOSEPH BUONGIORNO and J. KEITH GILLESS, *Forest Management and Economics: A Primer in Quantitative Methods* (1987). KARL F. WENGER (ed.), *Forestry Handbook,* 2nd ed. (1984), is a reference book of data and methods in all aspects of forestry and allied fields. GRANT W. SHARPE, CLARE W. HENDEE, and WENONAH F. SHARPE, *Introduction to Forestry,* 5th ed. (1986); and CHARLES H. STODDARD and GLENN M. STODDARD, *Essentials of Forestry Practice,* 4th ed. (1987), give a complete overview of modern multiple-use forestry. The requisite elements of forest inventory are detailed in BERTRAM HUSCH, CHARLES I. MILLER, and THOMAS W. BEERS, *Forest Mensuration,* 3rd ed. (1982). Financial implications are studied in G. ROBINSON GREGORY, *Resource Economics for Foresters* (1987). The leading international sources of statistics on forestry and timber output are the publications of the Food and Agriculture Organization of the United Nations: *World Forest Inventory* (irregular), *FAO Forestry and Forest Product Studies* (irregular); and the special reports *Forest Resources of Tropical Africa,* 2 vol. (1981), *Forest Resources of Tropical Asia* (1981), and *Forestry in China* (1982). Fundamental studies of the physical bases of forest distribution and yield are given in *World Resources 1986* (1986), a report prepared by the World Resources Institute and the International Institute for Environment and Development.

The theory and practice of raising and tending tree crops are treated in such manuals as THEODORE W. DANIEL, JOHN A. HELMS, and FREDERICK S. BAKER, *Principles of Silviculture,* 2nd ed. (1979); and DAVID M. SMITH, *The Practice of Silviculture,* 8th ed. (1986), discussing temperate-zone forests. Details of handling seed and young stock are treated in R.L. WILLAN (comp.), *A Guide to Forest Seed Handling: With Special Reference to the Tropics* (1985); U.S. DEPARTMENT OF AGRICULTURE, *Woody-Plant Seed Manual* (1948); and MARY L. DURYEA and THOMAS D. LANDIS (eds.), *Forest Nursery Manual: Production of Bareroot Seedlings* (1984). Genetic improvement is discussed in KLAUS STERN and LAURENCE ROCHE, *Genetics of Forest Ecosystems* (1974); and M.N. CHRISTIANSEN and CHARLES F. LEWIS (eds.), *Breeding Plants for Less Favorable Environments* (1982). The intensive culture of forest plantations is discussed in BRUCE J. ZOBEL, GERRIT VAN WYK, and PER STAHL, *Growing Exotic Forests* (1987); and W.E. HILLIS and A.G. BROWN (eds.), *Eucalypts for Wood Production* (1978, reprinted 1984). Management of forest soils, a primary concern in intensive silviculture, is described in WILLIAM L. PRITCHETT and RICHARD F. FISHER, *Properties and Management of Forest Soils,* 2nd ed. (1987); and PEDRO A. SANCHEZ, *Properties and Management of Soils in the Tropics* (1976). Manipulation of soil fertility and study of soil microorganisms are presented in G.D. BOWEN and E.K.S. NAMBIAR (eds.), *Nutrition of Plantation Forests* (1984); ROBERT L. TATE, III, and DONALD A. KLEIN (eds.), *Soil Reclamation Process: Microbiological Analyses and Applications* (1985); and J.C. GORDON and C.T. WHEELER (eds.), *Biological Nitrogen Fixation in Forest Ecosystems: Foundations and Applications* (1983). The care of tree crops in tropical jungles of both hemispheres is outlined in I.T. HAIG, M.A. HUBERMAN, and U. AUNG DIN, *Tropical Silviculture* (1958). A wide range of Asiatic conditions is discussed in HARRY G. CHAMPION and S.K. SETH, *General Silviculture for India* (1968).

The management of forests as watersheds and the impact of forestry activities on water quantity and quality are discussed in WILLIAM E. SOPPER and HOWARD W. LULL (eds.), *Forest Hydrology: Proceedings of a National Science Foundation Advanced Science Seminar* (1967); H.C. PEREIRA, *Land Use and Water Resources in Temperate and Tropical Climates* (1973); and K.W.G. VALENTINE, *Soil Resource Surveys for Forestry* (1986). Nutrient losses from disturbed watersheds and the potential for accelerated loss attributable to acid deposition are examined in F.E. CLARK and T. ROSSWALL (eds.), *Terrestrial Nitrogen Cycles: Processes, Ecosystem Strategies, and Management Impacts* (1981); and S. BEILKE and A.J. ELSHOUT (eds.), *Acid Deposition* (1983).

Forest protection is treated in textbooks discussing specific hazards. ARTHUR A. BROWN and KENNETH P. DAVIS, *Forest Fire: Control and Use,* 2nd ed. (1973), outlines fire dangers and methods of control. T.T. KOZLOWSKI and C.E. AHLGREN (eds.), *Fire and Ecosystems* (1974); and HENRY A. WRIGHT and ARTHUR W. BAILEY, *Fire Ecology, United States and Southern Canada* (1982), discuss the environmental interactions associated with fire. JOHN S. BOYCE, *Forest Pathology,* 3rd ed. (1961); and ROBERT O. BLANCHARD and TERRY A. TATTAR, *Field and Laboratory Guide to Tree Pathology* (1981), give details of fungal diseases, climatic dangers, and airborne fume and salt damage. See also CARL F. JORDAN (ed.), *Amazonian Rain Forests: Ecosystem Disturbance and Recovery* (1987). Insect pests are described in ALAN A. BERRYMAN, *Forest Insects: Principles and Practice of Population Management* (1986).

Wood production: The structure and properties of wood are treated in F.W. JANE, *The Structure of Wood,* 2nd ed., rev. by K. WILSON AND D.J.B. WHITE (1970); GEORGE TSOUMIS, *Wood as Raw Material: Source, Structure, Chemical Composition, Growth, Degradation, and Identification* (1968), mainly on structure, with keys for identification of North American and European commercial woods; A.J. PANSHIN and CARL DE ZEEUW, *Textbook of Wood Technology: Structure, Identification, Properties, and Uses of the Commercial Woods of the United States and Canada,* 4th ed. (1980); FRANZ P. KOLLMANN and WILFRED A. CÔTÉ, JR., *Principles of Wood Science and Technology,* vol. 1, *Solid Wood* (1968), on structure, chemical composition, and biologic deterioration, with detailed coverage of properties; ALFRED J. STAMM, *Wood and Cellulose Science* (1964), fundamental information on properties; H.E. DESCH, *Timber: Its Structure and Properties,* 6th ed., rev. by J.M. DINWOODIE (1981), including a discussion of drying, preservation, and grading; and JOZSEF BODIG and BENJAMIN A. JAYNE, *Mechanics of Wood and Wood Composites* (1982). JOHN G. HAYGREEN and JIM L. BOWYER, *Forest Products and Wood Science* (1982), provides basic information concerning physical and chemical properties of wood and the nature of major wood products. H.A. CORE, W.A. CÔTÉ, and A.C. DAY, *Wood Structure and Identification,* 2nd ed. (1979), contains photomicrographs of wood structure.

Basic principles of tree felling and timber haulage are covered in STEVE CONWAY, *Logging Practices: Principles of Timber Harvesting Systems,* rev. ed. (1982); GEORGE STENZEL, THOMAS A. WALBRIDGE, JR., and J. KENNETH PEARCE, *Logging and Pulpwood Production,* 2nd ed. (1985); and ROELOF A.A. OLDEMAN (ed.), *Tropical Hardwood Utilization: Practice and Prospects* (1982). Methods and machines evolve so rapidly that recent issues of a trade periodical, such as *World Wood* (bimonthly), should be consulted for current practice and equipment. An interesting historical overview of the industry is provided in KENNETH L. SMITH, *Sawmill: The Story of Cutting the Last Great Virgin Forest East of the Rockies* (1986).

Works on the commercial utilization of wood include A.J. PANSHIN *et al., Forest Products: Their Sources, Production, and Utilization,* 2nd ed. (1962), which provides general information on all products; FRANZ P. KOLLMANN and WILFRED A. CÔTÉ, JR., *Principles of Wood Science and Technology,* vol. 2, *Wood Based Materials* (1975); DARREL D. NICHOLAS (ed.), *Wood Deterioration and Its Prevention by Preservative Treatments,* 2 vol. (1973); FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS, *Plywood and Other Wood-Based Panels* (1966); and KENNETH W. BRITT (ed.), *Handbook of Pulp and Paper Technology,* 2nd rev. ed. (1970). Certain products (and properties) are discussed in the U.S. DEPARTMENT OF AGRICULTURE, *Wood Handbook: Wood as an Engineering Material,* rev. ed. (1987); and GERMAN GURFINKEL, *Wood Engineering,* 2nd ed. (1981), containing data for use in design and specification.

France

Historically and culturally among the most important nations in the Western world, the French Republic (République Française) has also played a highly significant role in international affairs, with former colonies in every corner of the globe. Bounded by the Atlantic Ocean and the Mediterranean Sea, the Alps and the Pyrenees, France has long provided a geographic, economic, and linguistic bridge joining northern and southern Europe. It is Europe's most important agricultural producer and one of the world's leading industrial powers.

France is among the globe's oldest nations, the product of an alliance of duchies and principalities under a single ruler in the Middle Ages. Today, as in that era, central authority is invested in the state, even though a measure of autonomy has been granted to the country's 22 *régions* in recent decades. The French people look to the state as the primary guardian of liberty, and the state in turn provides a generous program of amenities for its citizens, from free education to health care and pension plans. Even so, this centralist tendency is often at odds with another longstanding theme of the French nation: the insistence on the supremacy of the individual. On this matter historian Jules Michelet remarked, "England is an empire, Germany is a nation, a race, France is a person." Statesman Charles de Gaulle, too, famously complained, "Only peril can bring the French together. One can't impose unity out of the blue on a country that has 265 kinds of cheese."

This tendency toward individualism joins with a pluralist outlook and a great interest in the larger world. Even though its imperialist stage was driven by the impulse to civilize that world according to French standards (*la mission civilisatrice*), the French still note approvingly the words of writer Gustave Flaubert:

> I am no more modern than I am ancient, no more French than Chinese; and the idea of *la patrie*, the fatherland—that is, the obligation to live on a bit of earth coloured red or blue on a map, and to detest the other bits coloured green or black—has always seemed to me narrow, restricted, and ferociously stupid.

At once universal and particular, French culture has spread far and greatly influenced the development of art and science, particularly anthropology, philosophy, and sociology.

France has also been influential in government and civil affairs, giving the world important democratic ideals in the age of the Enlightenment and the French Revolution and inspiring the growth of reformist and even revolutionary movements for generations. The present Fifth Republic has, however, enjoyed notable stability since its promulgation on Sept. 28, 1958, marked by a tremendous growth in private initiative and the rise of centrist politics. Although France has engaged in long-running disputes with other European powers (and, from time to time, with the United States, its longtime ally), it emerged as a leading member in the European Union (EU) and its predecessors. From 1966 to 1995 France did not participate in the integrated military structure of the North Atlantic Treaty Organization (NATO), retaining full control over its own air, ground, and naval forces, though since 1995 France has been represented on the NATO Military Committee. As one of the five permanent members of the United Nations Security Council—together with the United States, Russia, the United Kingdom, and China—France has the right to veto decisions put to the council.

The capital and by far the most important city of France is Paris, one of the world's preeminent cultural and commercial centres. A majestic city known as the *ville lumière*, or "city of light," Paris has often been remade, most famously in the mid-19th century under the command of Georges-Eugène, Baron Haussman, who was committed to Napoleon III's vision of a modern city free of the choleric swamps and congested alleys of old, with broad avenues and a regular plan. Paris is now a sprawling metropolis, one of Europe's largest conurbations, but its historic heart can still be traversed in an evening's walk. Confident that their city stood at the very centre of the world, Parisians were once given to referring to their country as having two parts, Paris and *le désert*, the wasteland beyond it. Metropolitan Paris now extends far beyond its ancient suburbs into the countryside, however, and nearly every French town and village now numbers a retiree or two driven from the city by the high cost of living, so that, in a sense, Paris has come to embrace the desert and the desert Paris.

PHYSICAL AND HUMAN GEOGRAPHY

Land

France lies near the western end of the great Eurasian landmass, largely between latitudes 42° and 51° N. Roughly hexagonal in outline, its continental territory is bordered to the northeast by Belgium and Luxembourg, to the east by Germany, Switzerland, and Italy, to the south by the Mediterranean Sea, Spain, and Andorra, to the west by the Bay of Biscay, and to the northwest by the English Channel (La Manche). To the north, France faces southeastern England across the narrow Strait of Dover (Pas de Calais). Monaco is an independent enclave on the south coast, while the island of Corsica in the Mediterranean is treated as an integral part of the country.

RELIEF

The French landscape, for the most part, is composed of relatively low-lying plains, plateaus, and older mountain blocks, or massifs. This pattern clearly predominates over that of the younger, high ranges, such as the Alps and the Pyrenees. The diversity of the land is typical of Continental Europe.

The three geologic regions

Three main geologic regions are distinguishable: the skeletal remains of ancient mountains that make up the Hercynian massifs; the northern and western plains; and the higher young fold mountains in the south and southeast, including the Alps and the Pyrenees, with their attendant narrow plains. Much of the detailed relief can be attributed geologically to the varying differences in the resistance of rocks to erosion. A great deal of the present landscape detail is due to glaciation during the Pleistocene Epoch (1,600,000 to 10,000 years ago). France lay outside the range of the great ice sheets that descended upon northern Europe, so the direct sculpting of the land by ice was restricted to the Alps, the Pyrenees, the Vosges, Corsica, and the highest summits of the Massif Central. Just outside these glacial areas, in what are known as periglacial lands, repeated freezing and thawing of unprotected surfaces modified slopes by the movement of waste sheets (formed of shattered bedrock), producing very much the landscape that exists today. Pleistocene periglacial action generated the sheets of the fine windblown *limon*, or loess, that is the basis of the most fertile lowland soils, and it possibly also created the Landes, a sandy plain in southwestern France. The development of river terraces (flat, raised surfaces alongside valleys) was another characteristic of periglacial action.

The Hercynian massifs. The physical structure of France is dominated by a group of ancient mountains in the shape of a gigantic V, the sides of which form the two branches of Hercynian folding that took place between 345 and 225 million years ago. The eastern branch comprises the Ardennes, the Vosges, and the eastern part of the Massif Central, while the Hercynian massifs to the west comprise the western part of the Massif Central and the Massif Armoricain.

These highlands are composed of resistant metamorphic, crystalline, and sedimentary rocks from the Paleozoic Era (540 to 245 million years ago), the last including coal deposits. They share the common characteristic of repeated planation, or flattening.

The Ardennes. The Ardennes massif is an extension, from Belgium into France, of the great Rhine Uplands, characterized by rocks of slate and quartz from the Paleozoic Era. Differential erosion of Paleozoic rocks has produced long ridges alternating with open valleys crossed by the Sambre and Meuse rivers.

The Vosges. The Alpine earth movements produced a great upswelling along the line of the present upper Rhine, leaving the Vosges with steep eastern slopes that descend to a rift valley containing the plains of Alsace and Baden; on the west the upland descends rather gently into the scarplands of Lorraine. The Vosges reaches its maximum elevation in the south, near the Alps, where crystalline rocks are exposed; the highest summits are called *ballons*, and the highest is the Ballon de Guebwiller (Mount Guebwiller), with an elevation of 4,669 feet (1,423 metres). To the north the Vosges massif dips beneath a cover of forested sandstone from the Triassic Period (245 to 208 million years ago).

The *ballons*

The Massif Central. The vast plateau of the Massif Central covers about 33,000 square miles (86,000 square km), or some one-sixth of the area of the country. The Massif Central borders the Rhône-Saône valley to the east, the Languedoc lowlands to the south, the Aquitaine Basin to the southwest, and the Paris Basin to the north. Much of the western massif, notably Limousin, consists of monotonous erosion surfaces. The centre and eastern parts of the massif were much fractured in the course of the Alpine movements, leaving behind upthrust blocks, of which the

Cinder cones of the Chaîne des Puys in the Massif Central.
© Christian Kempf from TSW—CLICK/Chicago

most conspicuous is the Morvan, the forested bastion of the northeastern corner of the massif. Downfaulted basins filled with Tertiary sediments (those formed 66.4 to 1.6 million years ago), such as the Limagne near the city of Clermont-Ferrand in south-central France, were also formed. Faulting was associated with volcanic activity, which in the central part of the region formed the vast and complex structures of the massifs of Cantal and Monts Dore, where the Sancy Hill (Puy de Sancy), at 6,184 feet, is the highest summit of the Massif Central. Farther west, on the fringe of the Limagne, is the extraordinary Chaîne des Puys, whose numerous cinder cones were formed only about 10,000 years ago and still retain the newness of their craters, lava flows, and other volcanic features. Numerous mineral springs, such as those at Vichy in the central Auvergne region, are a relic of volcanic activity.

The eastern and southern Massif Central

The eastern and southern portions of the massif, from the Morvan through the Cévennes to the final southwestern termination of the massif in the Noire Mountains (Montagne Noire), are marked by a series of hill masses that overlook the lowlands of the Rhône-Saône river valley and the *région* of Languedoc-Roussillon; at least one of these uplands, Beaujolais, has become famous for the grapevines grown at its foot. Between the hill masses lie infolded coal deposits at locations such as Alès, Decazeville, Saint-Étienne, and Blanzy (Le Creusot) that are of more historical than contemporary importance. To the southwest the rocks of the massif are overlain by a great thickness of limestones (*causses*) from the Jurassic Period (208 to 144 million years ago). Lacking in surface water and little populated, this portion of the massif is crossed by rivers that trench dramatic gorges, notably that of the Tarn. Extensive cave systems bear remains of prehistoric art, such as that of Pêche-Merle in the Lot valley and the Lascaux Grotto in the Vézère valley.

The Massif Armoricain. The Massif Armoricain is contained mostly within the *région* of Brittany (Bretagne), a peninsula washed by the Bay of Biscay on the south and the English Channel on the north. The massif continues beyond Brittany eastward and across the Loire to the south. It is much lower than the other Hercynian massif; its highest point, the Mont des Avaloirs, on the eastern edge of the massif, attains an elevation of 1,368 feet.

The great lowlands. *The Paris Basin.* Between the Ardennes, the Vosges, the Massif Central, and the Massif Armoricain lie the sedimentary beds that make up the Paris Basin. Alternating beds of limestone, sand, and clay dip toward the central Paris Basin, their outcrops forming concentric patterns. Especially to the east, erosion has left the more resistant rocks, usually limestones, with a steep, outward-facing scarp edge and a gentler slope toward the centre of the basin. The central Paris Basin is filled by Tertiary rocks, mostly limestones, that form the level plateaus of regions such as Beauce, Brie, Île-de-France, Valois, and Soissonnais. This area is mostly covered with windblown *limon*, which is the basis of an excellent loamy soil. The limestone levels overlap in sandwich formation. Eroded remnants of higher formations have been left behind as isolated hills called buttes, perhaps the most famous of which is in Paris—the Butte de Montmartre, on which is one of the city's most famous districts. Sandy areas adjoining the limestone formations bear forests, such as the Forest of Fontainebleau, southwest of Paris. In the east, in the regions of Lorraine and Burgundy, are Triassic and Jurassic rocks; among the scarps the Moselle Hills are noted for their *minette*, low-grade iron ore. In the western part of the Paris Basin, scarps in the Jurassic and Cretaceous rocks of Normandy are not prominent. The chalk plateau is trenched by the lower Seine in a course marked by spectacular meanders and river cliffs. Farther north, many stretches of magnificent white chalk cliffs line the English Channel coast.

The chalk plateau

The Flanders Plain. In the extreme north the French boundary includes a small part of the Anglo-Belgian basin. Coastal sand dunes protect the reclaimed marshes of French Flanders from invasion by the sea.

The Alsace Plain. East of the Paris Basin is the Alsace Plain. The terrace and foothills bordering the Rhine are covered with soil-enriching *limon*. Alluvial fans, which are laid down by tributaries emerging from the Vosges, and much of the floodplain of the Rhine and its major tributary, the Ill River, are forested. The Sundgau region of the Alsace Plain, which lies between the Jura and the Ill River above Mulhouse, is another great alluvial fan overlaying impermeable clays, which hold up numerous lakes. The Rhine River and its tributaries continue to deposit thick sediments on the floodplain.

The Loire plains. Toward the southwest the Paris Basin opens on a group of plains that follow the Loire valley. The hills of this area, such as the limestone plateaus of the Touraine region and the crystalline plateaus of the Anjou and Vendée areas, are cut by the broad valleys of the Loire and its tributaries. The middle Loire valley, which varies in width from about 3 to 6 miles (about 5 to 10 kilometres), is famous for its châteaus and its scenic beauty.

The Aquitaine Basin. The Loire countryside links with the Aquitaine Basin of southwestern France through the gap known as the Gate of Poitou. The Aquitaine Basin is much smaller than the Paris Basin, and, while it is bounded in the south by the Pyrenees, in the northeast it runs into the low foothills of the Massif Central.

The younger mountains and adjacent plains. *Pyrenees, Jura, and Alps.* The Pyrenees, whose foothills shelter the picturesque countryside of the Basque region, constitute the most ancient of the more recently formed mountains in France. They stretch for more than 280 miles (450 kilometres), making a natural barrier between France and Spain. Their formation, which began in the Mesozoic Era (245 to 66.4 million years ago), continued in the Tertiary and perhaps even in the beginning of the Quaternary, about 1.6 million years ago. The central and highest part of the barrier is composed of a series of parallel chains with only a few, difficult-to-reach passes that have sheer drops. A section of the mountain chain centring on Mont Perdu (Spanish: Monte Perdido) was named a UNESCO World Heritage site in 1997.

The Jura Mountains, extending into Switzerland, are composed of folded limestone. The northeastern part of the Jura, which has the most pronounced folding, is in Switzerland. The highest point, however, is Mount Neige (5,636 feet), in France.

The French Alps are only a part of the great chain that extends across Europe, but they include its highest point, Mont Blanc (15,771 feet [4,807 metres]). These majestic mountains were formed in a series of foldings that lasted from the beginning of the Tertiary to the Quaternary Peri-

od. They include the two greatest regions of permanent snow and glaciers in Europe. The northern Alps are relatively easy to cross because of the numerous valleys created by the movement of glaciers. The relief of the southern Alps is much less orderly, and the valleys, which were not affected by glaciation, form narrow and winding gorges. Like the Pyrenees, the Alps form a natural barrier, dropping sharply down to the Po River plain in Italy.

The French Riviera

The southern plains. Between these young mountains and the ancient Massif Central is a series of plains, including those of the Saône and the Rhône rivers, which extend southward to the great triangular delta of the Rhône on the Mediterranean coast. Its seaward face, the Camargue region, comprises a series of lakes, marshes, and sand spits and includes one of Europe's important wetland nature reserves. West of the Rhône delta the Languedoc coastal plain is broad and rather featureless. At the southwestern end the foothills of the Pyrenees reach to the rocky coast of the Roussillon region. East of the Rhône delta the lowlands are more fragmentary; in the Côte d'Azur region the Alpine foothills and the ancient Maures and Esterel massifs reach to the Mediterranean, forming the coves, capes, and harbours of the country's most famous tourist and retirement area, the French Riviera. Corsica is also highly regarded for its natural scenery. A number of the island's peaks reach over 6,500 feet, with parts of it under wild forest or covered with undergrowth, or maquis.

DRAINAGE

The river systems of France are determined by a major divide in the far eastern part of the country, running from the southern end of the Vosges down the eastern and southeastern edge of the Massif Central to the Noire Mountains, the southwestern promontory of the massif. This divide is broken by occasional cols (depressions) and lowland corridors, notably the Langres Plateau, across the Jurassic outer rim of the Paris Basin. Along the divide originate most of the rivers of the larger, western part of the country, including the Seine and the Loire. Other major rivers include the Garonne, originating in the Pyrenees, and the Rhône and the Rhine, originating in the Alps.

The Seine system. The main river of the Paris Basin, the Seine, 485 miles in length, is joined upstream on the left bank by its tributary the Yonne, on the right bank south of Paris by the Marne, and north of the city by the Oise. While the Seine has a regular flow throughout the year, there may be flooding in the spring and, occasionally more severely, during the customary fall-winter peak of lowland rivers. Efforts have been made to reduce flooding on the Seine and its tributaries by the building of reservoirs. A number of islands dot the Seine along its meandering, generally westward course across the central Paris Basin and through the capital city itself. One of these, the Île de la Cité, forms the very heart of the city of Paris. Eventually the river enters the English Channel at Le Havre.

The Loire system. The Loire, the longest French river, flows for 634 miles and drains the widest area (45,000 square miles). It is an extremely irregular river, with an outflow eight times greater in December and January than in August and September. Rising in the Massif Central on Mount Gerbier-de-Jonc, it flows northward over impervious terrain, with many gorgelike sections. Near Nevers it is joined by the Allier, another river of the massif. Within the Paris Basin the Loire continues to flow northward, as if to join the Seine system, but then takes a wide bend to the west to enter the Atlantic past Nantes and Saint-Nazaire. The Loire is artificially joined to the Seine by several

canals. The river's torrential flow, a hindrance to navigation, covers its floodplain with sand and gravel, which has commercial importance. The river is also a source of cooling water for a chain of atomic power stations near its course, which has raised concerns among environmentalists, as have various dam projects along the river. UNESCO designated the valley between Sully-sur-Loire and Chalonnes a World Heritage site in 2000.

The Garonne system. The Garonne, in the southwest, flows through the centre of the Aquitaine Basin. It is the shortest of the main French rivers, with a length of 357 miles, and it drains only 21,600 square miles. Its outflow is irregular, with high waters in winter (due to the oceanic rainfall) and in spring, when the snow melts, but with meagre flows in summer and autumn. Its source is in the central Pyrenees in the Aran (Joyeuse) Valley in Spain, and its main tributaries, the Tarn, the Aveyron, the Lot, and the Dordogne, originate in the Massif Central. With some exceptions, the whole network is generally useless for navigation and is filled with powerful, rapid, and dangerous currents.

Source of the Garonne

The Rhône system. In eastern France the direction of the main rivers is predominantly north-south through the Alpine furrow. The Rhône is the great river of the southeast. Rising in the Alps, it passes through Lake Geneva (Lac Léman) to enter France, which has 324 miles of its total length of 505 miles. At Lyon it receives its major tributary, the Saône. The regime of the Rhône is complex. Near Lyon the Rhône and its important Isère and Drôme tributaries, draining from the Alps, have a marked late spring–early summer peak caused by the melting of snow and ice. The course of the river and the local water tables have been much modified by a series of dams to generate power and to permit navigation to Lyon. The Rhône also supplies cooling water to a series of atomic power stations. West of the Rhône the Bas Rhône–Languedoc canal, constructed after World War II to provide irrigation, has proved to be an essential element in the remarkable urban and industrial development of Languedoc. East of the Rhône the Canal de Provence taps the unpolluted waters of a Rhône tributary, the Durance, supplying Aix-en-Provence, Marseille, Toulon, and the coast of Provence with drinking water and providing impetus for urban expansion. At its delta, beginning about 25 miles from the Mediterranean, the Rhône and its channels deposit significant amounts of alluvium to form the Camargue region.

The Rhine system. The Rhine forms the eastern boundary of France for some 118 miles. In this section its course is dominated by the melting of snow and ice from Alpine headstreams, giving it a pronounced late spring–summer peak and often generally low water in autumn. The Ill, which joins the Rhine at Strasbourg, drains southern Alsace. The Rhine valley has been considerably modified by the construction on the French side of the lateral Grand Canal d'Alsace, for power generation and navigation. The eastern Paris Basin is drained by two tributaries, the Moselle, partly canalized, and the Meuse.

The lakes. The French hydrographic system also includes a number of natural lakes of different origin. There are the lakes in depressions carved out by glaciation at the western periphery of the Alps, such as the lakes of Annecy and Bourget, the latter being the largest natural lake entirely within France. Others occur on the surfaces of ancient massifs and include the lakes of the Vosges. Some lakes are caused by structural faults and are lodged in narrow valleys, as are the Jura lakes. There are also lakes of volcanic origin, such as those in the Massif Central (crater lakes and lakes ponded behind lava flows), and regions scattered with lagoons or ponds, either created by coastal phenomena, as on the Landes (Atlantic) and Languedoc (Mediterranean) coasts, or caused by impervious terrain and poor local drainage, as in the Sologne plain. Major artificial lakes include the Serre-Ponçon reservoir, on the Durance River in the Alps, and the Sarrans and Bort-les-Orgues reservoirs, both in the Massif Central.

Alpine lakes

SOILS

On a broad, general scale, virtually the whole of France can be classified in the zone of brown forest soils, or brown earths. These soils, which develop under deciduous forest cover in temperate climatic conditions, are of excellent agricultural value. Some climate-related variation can be detected within the French brown earth group; in the high-rainfall and somewhat cool conditions of northwestern France, carbonates and other minerals tend to be leached downward, producing a degraded brown earth soil of higher acidity and lesser fertility; locally this may approach the nature of the north European podzol. The brown earth zone gives way southward to the zone of Mediterranean soils, which in France cover only a limited area. They are developed from decalcified clays with a coarse sand admixture and are typically red in colour because of the up-

ward migration of iron oxides during the warm, dry summers. These soils can be quite fertile.

The *limon*

Over large areas of France, soils have developed not directly from the disintegrated bedrock but from the waste sheets created by periglacial action. These may provide a particularly favourable soil material; most notable is the windblown *limon* that mantles the Tertiary limestone plateaus of the central Paris Basin and the chalk beds to the northwest, the basis of the finest arable soils of France. Limestone and chalk enrich soils with lime, which is generally favourable, but there is a marked north-south contrast. The limestone areas of southern France tend to be swept almost bare of soil by erosion; the soil then collects in valleys and hollows. The soils of the higher mountains are naturally stony and unfavourable.

CLIMATE

Three major climatic zones

The climate of France is generally favourable to cultivation. Most of France lies in the southern part of the temperate zone, although the subtropical zone encompasses its southern fringe. All of France is considered to be under the effect of oceanic influences, moderated by the North Atlantic Drift to the west and the Mediterranean Sea to the south. Average annual temperatures decline to the north, with Nice on the Côte d'Azure at 59° F (15° C) and Lille on the northern border at 50° F (10° C). Rainfall is brought mainly by westerly winds from the Atlantic and is characterized by cyclonic depressions. Annual precipitation is more than 50 inches (1,270 millimetres) at higher elevations in western and northwestern France, in the western Pyrenees, in the Massif Central, and in the Alps and the Jura. In winter eastern France especially may come under the influence of the continental high-pressure system, which brings extremely cold conditions and temperature inversions over the cities, during which cold air is trapped below warmer air, with consequent fogs and urban pollution. The climate of France, then, can be discussed according to three major climatic zones—oceanic, continental, and Mediterranean, with some variation in the Aquitaine Basin and in the mountains.

PLANT AND ANIMAL LIFE

Plant life. Vegetation is closely related to climate, so that in France it is not surprising that there are two major but unequal divisions: the Holarctic province and the smaller Mediterranean province. Most of France lies within the Holarctic biogeographic vegetational region, characterized by northern species, and it can be divided into three parts. A large area of western France makes up one part. It lies north of the Charente River and includes most of the Paris Basin. There the natural vegetation is characterized by oak (now largely cleared for cultivation), chestnut, pine, and beech in uplands that receive more than 23.6 inches of annual rainfall. Heathland is also common, as a predominantly man-made feature (created by forest clearance, burning, and grazing). Broom, gorse, heather, and bracken are found. South of the Charente, the Aquitaine Basin has a mixture of heath and gorse on the plateaus and several varieties of oak, cypress, poplar, and willow in the valleys. On the *causses* of the Massif Central and on other limestone plateaus, broom, heath, lavender, and juniper appear among the bare rocks. The vegetation of eastern France, constituting a second part of the Holarctic division, is of a more central European type, with trees such as Norway maple, beech, pedunculate oak, and larch; hornbeam is often present as a shrub layer under oak. The various high mountain zones form a third Holarctic part; with cloudy and wet conditions, they have beech woods at lower elevations, giving way upward to fir, mountain pine, and larch but with much planted spruce. Above the tree line are high mountain pastures, now increasingly abandoned, with only stunted trees but resplendent with flowers in spring and early summer.

Vegetation of the Mediterranean zone

The second major vegetation division of the country lies within the Mediterranean climatic zone and provides a sharp contrast with the plant life elsewhere in France. The pronounced summer drought of this zone causes bulbous plants to die off in summer and encourages xerophytic plants that retard water loss by means of spiny, woolly, or glossy leaves; these include the evergreen oak, the cork oak, and all the heathers, cistuses, and lavenders. Umbrella, or stone, pine and introduced cypress dominate the landscape. The predominant plant life of the plateaus of Roussillon is the maquis, comprising dense thickets of drought-resistant shrubs, characterized in spring by the colourful flowers of the cistuses, broom, and tree heather; in most areas this is a form that has developed after human destruction of the evergreen forest. A large part of Provence's hottest and driest terrain is covered by a rock heath known as garigue. This region is a principal domain of the vineyard, but lemon and orange trees grow there also. At elevations of about 2,600 feet, as in the Cévennes, deciduous forest appears, mainly in the form of the sweet chestnut. At elevations of 4,500 feet this gives way to a subalpine coniferous forest of fir and pine.

Forest covers 58,000 square miles of France (15,000,000 hectares), which is more than a quarter of its territory. Most forests are on the upland massifs of the Ardennes and Vosges and within the Jura, Alps, and Pyrenees mountain chains, but extensive lowland forests grow on areas of poor soil, such as that of the Sologne plain south of the Loire River. The planted forest of maritime pine covering about 3,680 square miles (953,000 hectares) in the Landes of southwestern France is said to be the most extensive in western Europe. Increasingly, forests are less a source of wood and more a recreational amenity, especially those on the fringe of large urban agglomerations, such as Fontainebleau and others of the Île-de-France region.

Animal life. The fauna of France is relatively typical of western European countries. Among the larger mammals are red deer, roe deer, and wild boar, which are still hunted; the fallow deer is rather rare. In the high Alps are the rare chamoix and the reintroduced ibex. Hares, rabbits, and various types of rodents are found both in the forests and in the fields. Carnivores include the fox, the genet, and the rare wildcat. Among endangered species are the badger, the otter, the beaver, the tortoise, the marmot of the Alps, and the brown bear and the lynx of the Pyrenees. Seals have almost entirely disappeared from the French coasts. While French bird life is in general similar to that of its neighbours, southern France is at the northern edge of the range of African migrants, and such birds as the flamingo, the Egyptian vulture, the black-winged stilt, the bee-eater, and the roller have habitats in southern France.

People

ETHNIC GROUPS

The Basques

The French are, paradoxically, strongly conscious of belonging to a single nation, but they hardly constitute a unified ethnic group by any scientific gauge. Before the official discovery of the Americas at the end of the 15th century, France, located on the western extremity of the Old World, was regarded for centuries by Europeans as being near the edge of the known world. Generations of different migrants traveling by way of the Mediterranean from the Middle East and Africa and through Europe from Central Asia and the Nordic lands settled permanently in France, forming a variegated grouping, almost like a series of geologic strata, since they were unable to migrate any farther. Perhaps the oldest reflection of these migrations is furnished by the Basque people, who live in an isolated area west of the Pyrenees in both Spain and France, who speak a language unrelated to other European languages, and whose origin remains unclear. The Celtic tribes, known to the Romans as Gauls, spread from central Europe in the period 500 BC–AD 500 to provide France with a major component of its population, especially in the centre and west. At the fall of the Roman Empire, there was a powerful penetration of Germanic (Teutonic) peoples, especially in northern and eastern France. The incursion of the Norsemen (Vikings) brought further Germanic influence. In addition to these many migrations, France was, over the centuries, the field of numerous battles and of prolonged occupations before becoming, in the 19th and especially in the 20th century, the prime recipient of foreign immigration into Europe, adding still other mixtures to the ethnic melting pot.

LANGUAGES

French is the national language, spoken and taught everywhere. Brogues and dialects are widespread in rural areas, however, and many people tend to conserve their regional linguistic customs either through tradition or through a voluntary and deliberate return to a specific regional dialect. This tendency is strongest in the frontier areas of France. In the eastern and northern part of the country, Alsatian and Flemish (Netherlandic) are related to the Germanic languages; in the south, Occitan (Provençal or Languedoc), Corsican, and Catalan show the influence of Latin. Breton is a Celtic language related to languages spoken in some western parts of the British Isles (notably Wales), and Basque is a language isolate. Following the introduction of universal primary education during the Third Republic in 1872, the use of regional languages was rigorously repressed in the interest of national unity, and pupils using them were punished. More recently, in reaction to the rise in regional sentiment, these languages have been introduced in a number of schools and universities, primarily because some of them, such as Occitan, Basque, and Breton, have maintained a literary tradition. Recent immigration has introduced various non-European languages, notably Arabic.

RELIGION

About three-fourths of the French people belong to the Roman Catholic church. Only a minority, however, regularly participate in religious worship; practice is greatest among the middle class. The northwest (Brittany-Vendée), the east (Lorraine, Vosges, Alsace, Jura, Lyonnais, and the northern Alps), the north (Flanders), the Basque Country, and the region south of the Massif Central have a higher percentage of practicing Roman Catholics than the rest of the country. Recruitment of priests has become more difficult, even though the church, historically autonomous, is very progressive and ecumenical.

Protestant sects

Reflecting the presence of immigrants from North Africa, Algeria, and Morocco, France has one of Europe's largest Muslim populations: more than 4,000,000 Muslims, a sizable percentage of them living in and around Marseille in southeastern France, as well as in Paris and Lyon. Protestants, who number 700,000, belong to several different denominations. They are numerous in Alsace, in the northern Jura, in the southeastern Massif Central, and in the central Atlantic region. There are more than 700,000 adherents of Judaism, concentrated in greater Paris, Marseille, and Alsace and the large eastern towns. In addition to the religious groups, there also are several societies of freethinkers, of which the most famous is the French Masonry. Large numbers, however, especially among the working class and young population, profess no religious belief.

SETTLEMENT PATTERNS

Rural landscape and settlement. Centuries of human adaptation of the various environments of France have produced varied patterns of rural landscape. Scholars have traditionally made an initial contrast between areas of enclosed land (*bocage*), usually associated with zones of high rainfall and heavy soils, and areas of open-field land (*campagne*), generally associated with level and well-drained plains and plateaus. Two other patterns have evolved in the Mediterranean region and in the mountains.

Bocage. In its classic form, *bocage* is found in Brittany, where small fields are surrounded by drainage ditches and high earthen banks, from which grow impenetrable hedges arching over narrow sunken lanes. Similarly enclosed land is found elsewhere, however, notably on the northern, western, and southern fringes of the Paris Basin, such as in Normandy, as well as in the western and northern parts of the Massif Central, parts of Aquitaine, and the Pyrenean region. At higher levels hedges may be replaced by stone walls. Settlement mostly takes the form of hamlets and isolated farms.

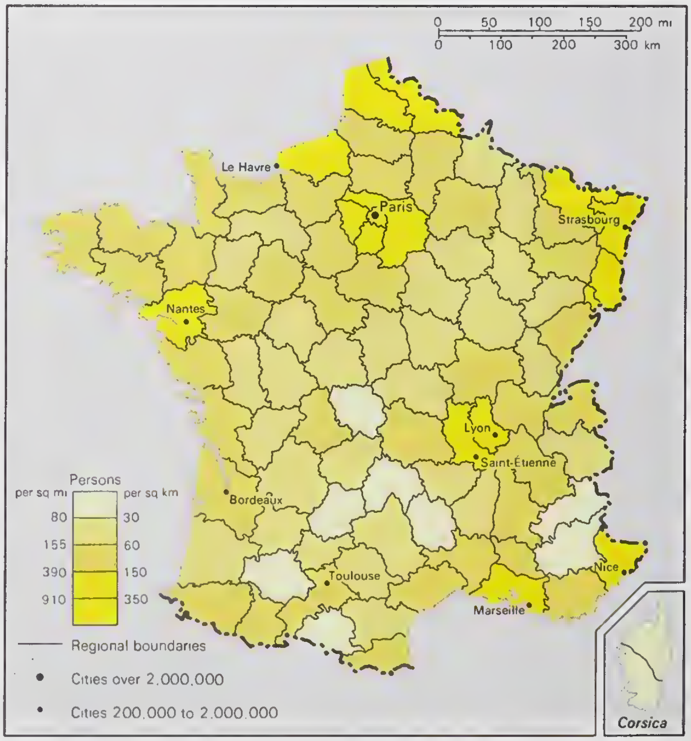
Open-field. The greatest extent of open-field land is found in the Paris Basin and in northern and eastern France, but there are pockets of it elsewhere. The landscape typically lacks hedges or fences; instead, the bewildering pattern of small strips and blocks of land is defined by small boundary stones. The land of one farmer may be dispersed in parcels scattered over a wide area. The land is predominantly arable, and the farmsteads are traditionally grouped into villages, which may be irregularly clustered or, as in Lorraine, linear in form.

Mediterranean. The generally block-shaped Mediterranean lowland parcels normally are not enclosed or are enclosed only by rough stone banks. However, in areas where delicate crops would be exposed to wind damage, there are screens of willows and tall reeds. Hillsides are frequently terraced, although much of this land type has been abandoned except in areas of intensive cultivation, such as the flower-growing region around Grasse. A very large farmhouse built on three floors is characteristic of wine-growing and sheep-raising regions, such as Provence. Rural population was formerly often clustered at high elevations, both for defense and in order to be above the malarial plains. In modern times there has been a move to more convenient lowland locations.

The *adrets* and *ubacs*

Mountain. In the high mountains and especially in the Alps, there is a contrast between the *adrets*, the sunny and cultivated valley slopes, and the *ubacs*, the cold and humid slopes covered with forests. The variety of vegetation on the slopes of the mountains is remarkable. Cultivated fields and grasslands are found in the depths of the valleys, followed in ascending order by orchards on the first sunny embankments, then forests, Alpine pastures, bare rocks, and, finally, permanent snow. A unique aspect of the mountain environment is that Alpine villages of the lower valley sides were often combined with *chalets* (*burons* in the Massif Central), temporary dwellings used by those tending flocks on summer pastures above the tree line.

Postwar transformation. After World War II the French government instituted a program of consolidation, whereby the scattered parcels of individual farmers were grouped into larger blocks that would accommodate heavier, mechanized cultivation. Initially progress was greatest in the open-field areas, particularly the Paris Basin, where there were few physical obstacles to the process. Subsequent extension to *bocage* areas had more severe consequences for landscape values and ecology, as hedges, sunken lanes, and ponds disappeared in favour of a new open landscape. At the same time, the vast numbers of people abandoning agricultural pursuits enormously changed the nature of



Population density of France.

rural settlement. Particularly in the more attractive areas, abandoned farms were purchased as second homes or for retirement. Where alternative employment was available, rural people stayed and became commuters, transforming barns and stables for other uses, such as garages. On the fringes of the expanding city regions, new houses and housing subdivisions for urban commuters were built in the villages, markedly changing their character.

Urban settlement. The primacy of Paris as the predominant urban centre of France is well known. After World War II the French government had an ambivalent attitude toward the development of the urban structure. On the one hand there was the desire to see Paris emerge as the effective capital of Europe, and on the other there was the policy of creating "*métropoles d'equilibre*," through which cities such as Lille, Bordeaux, and Marseille would become growth poles of regional development. Even more evident was the unplanned urbanization of small and medium-size towns related to spontaneous industrial decentralization from Paris, such as that along the Loire valley, or to retirement migration, such as that along the coastlands of southern France.

DEMOGRAPHIC TRENDS

In the second half of the 20th century, France's high postwar birth rate slowed, and about 1974 it fell into a sharp decline, eventually reaching a point insufficient for the long-term maintenance of the population. Since mid-century, because of a corresponding decline in the death rate, the rate of natural increase (balance of births against deaths) has remained positive, though declining. By the late 1990s France had an average population increase of more than 250,000 people each year. These changes were not exceptional to France; the same postwar pattern was largely paralleled in neighbouring countries. A number of factors combined to reduce the birth rate, among them the introduction of the contraceptive pill and the new preference for smaller families.

Emigration. Unlike many of its neighbours, France has never been a major source of international migrants, though in centuries past some left because of religious persecution (the Huguenots), while others settled in parts of France's colonial domain. Now, small numbers of French, especially from Brittany and Normandy, continue to relocate to Canada, and a number of Basques go to Argentina.

Immigration. From the middle of the 19th century there has been a substantial flow of immigrants into France, with waves of immigrants arriving especially after the two World Wars. France had the reputation into the early 20th century of being the European country most open to immigrants, including political refugees, but this reputation changed in the late 20th century, when opposition rose to continued immigration from Africa. Although immigration flattened out after 1974, natural increase dropped, so that immigration continued to contribute significantly to population growth. At the end of the century, there were more than three million foreigners resident in France, amounting to some 6 percent of the population, a proportion that had remained constant since 1975. Neighbouring countries such as Portugal, Italy, and Spain continued to be significant contributors, but recent immigrant streams came from North Africa, notably Algeria (an integral part of France until 1962) and the former protectorates of Morocco and Tunisia. Peoples from French or former French territories in Central Africa, Asia, and the Americas provided an additional source of immigrants.

Effects of wars on population trends

As the numbers of immigrants grew, so did incidents of racial discrimination in housing and employment, as well as social activism among immigrant groups. Initially, immigrants from Africa and the Americas were predominantly males, living in low-standard housing and working in undesirable, low-skilled occupations. As families were progressively reconstituted, immigrants continued to work in jobs that Frenchmen were reluctant to accept. With the beginning of an economic downturn in 1974, though, French workers began to reclaim some of the jobs held by immigrants, and the government began to restrict immigration. Adding to the job competition were approximately one million persons with French citizenship, the so-called *pieds-noirs* (literally "black feet"), who were repatriated from territories in North Africa decolonized in 1962–64. The policy of restricting immigration remains in force, with the result that in the early 21st century the net annual increase of population from immigration averaged little more than 50,000 people. With the enactment in 1999 of the Amsterdam Treaty in France, many issues of immigration became shared by participating members of the European Union.

Repatriation from North Africa

Population structure. The aging of the population is common to western Europe, but because of low birth rates it has been observable in France since the beginning of the 19th century. By the end of the 20th century, one-fifth of French citizens were at least 60 years old. The tendency for the proportion of the elderly population to increase also reflects medical advances, which have produced a longer expectation of life. The age structure of the population is of considerable social and economic importance. The steady increase in the proportion of the aged puts an increasing strain on the working population to provide pensions, medical and social services, and retirement housing. The increase in births between 1944 and the mid-1970s, however, brought its own problems, notably the need to rush through a school-building program, followed by the creation of new universities. But this demographically young population also stimulated the economy by creating a greater demand for consumer goods and housing.

Another important aspect of population structure is the proportion of men to women, in society as a whole and in the various age groups. As in most western European countries, women outnumber men in French society, particularly in the older age groups, which is the result of two factors: the wars, which caused the death of a large number of men, and the natural inequality of life expectancy for men and women. A French woman at birth has one of the highest life expectancies in the world (83 years), while a man's is much lower (75 years), although still relatively high when compared with the world in general. The ratio of men to women in employment is another measure of population structure, and in the late 20th century women steadily increased their share of the job market.

Proportion of men to women

Population distribution. Particularly low population densities are characteristic of the mountain regions, such as the Massif Central, the southern Alps, the Pyrenees, and Corsica, but are also reflected in some lowland rural areas, such as the eastern and southern Paris Basin and large parts of Aquitaine. The four least-populated French *régions*—Corsica, Limousin, Franche-Comté, and Auvergne—have one-sixteenth of the national population in about one-eighth of the area. By contrast, the four most populated French *régions*—Île-de-France (Paris region), Rhône-Alpes, Provence-Alpes-Côte d'Azur, and Nord-Pas-de-Calais—have more than two-fifths of the French population in less than one-fifth of the area. Other high-density areas are the industrial cities of Lorraine; isolated large cities, such as Toulouse; and certain small-farm areas, such as coastal Brittany, Flanders, Alsace, and the Limagne basin of Auvergne.

Until about the mid-19th century, rural and urban populations both increased; thereafter there was a marked depopulation of the more remote, mostly mountainous, rural areas and a swing to urban growth. In the space of a century, from the 1860s to the 1960s, rural population decreased by more than one-third, though since that time it has remained constant. There were still as many rural as urban inhabitants even up to the period between the two World Wars, but since the 1980s three-fourths of the population has been urban. Postwar rural depopulation was associated with the exodus of labour following the modernization of French agriculture and the growth of urban industrial regions.

Rural depopulation

From about 1975, the older industrial *régions*, such as Nord-Pas-de-Calais and Lorraine, were in decline and became regions of out-migration. The most dramatic reversal was that of the deindustrialized Île-de-France *région*; although still the greatest population concentration of France, it had a negative migration balance after 1975. Growth subsequently switched to the south, to the coastlands of Languedoc and of Provence-Alpes-Côte d'Azur;

to the west, in the Atlantic *régions* of Poitou-Charentes and Pays de la Loire; and to the southwest, in the Midi-Pyrénées and Aquitaine *régions*. These shifts reflect a combination of economic decentralization, retirement migration, sunbelt industrialization, changing residential preferences, and expanding tourism. Population increase has also been strong on the southern and western fringes of the Paris Basin, favoured for industrial decentralization from the Île-de-France *région*.

Suburbanization

In the first half of the 20th century, suburban growth, where it did occur, was not the result of middle-class suburbanization, as it was in the United States and the United Kingdom. It was the working class and the lower middle class that moved out of Paris, while higher-income groups endeavoured to maintain a foothold in the central city. In the postwar period, however, suburbanization took increasingly middle-class forms, with the building up of satellite low-density subdivisions known as "new villages." Similar postwar suburbanization occurred in cities such as Marseille, Lyon, Lille, and Bordeaux.

Increasingly, the most rapid population growth is relegated to small towns and nominally rural communes on the expanding fringes of the city regions. This dispersal of population is associated with an increasing length of daily commuter movements, with all their human disadvantages, as well as other problems of urban sprawl.

(T.H.El./J.N.T./Ed.)

Economy

France is one of the major economic powers of the world, ranking along with such countries as the United States, Japan, Germany, Italy, and the United Kingdom. Its financial position reflects an extended period of unprecedented growth that lasted for much of the postwar period until the mid-1970s; frequently this period was referred to as the *trente glorieuses* ("thirty years of glory"). Between 1960 and 1973 alone, the increase in gross domestic product (GDP) averaged nearly 6 percent each year. In the aftermath of the oil crises of the 1970s, growth rates were moderated considerably and unemployment rose substantially. By the end of the 1980s, however, strong expansion was again evident. This trend continued, although at a more modest rate, through the end of the century.

Despite the dominance of the private sector, the tradition of a mixed economy in France is well established. Successive governments have intervened to protect or promote different types of economic activity, as has been clearly reflected in the country's national plans and nationalized industries. In the decades following World War II, the French economy was guided by a succession of national plans, each covering a span of approximately four to five years and designed to indicate rather than impose growth targets and development strategies.

The public sector in France first assumed importance in the post-World War II transition period of 1944–46 with a series of nationalizations that included major banks such as the National Bank of Paris (Banque Nationale de Paris; BNP) and Crédit Lyonnais, large industrial companies such as Renault, and public services such as gas and electricity. Little change took place after that until 1982, when the then-Socialist government introduced an extensive program of nationalization. As a result, the enlarged public sector contained more than one-fifth of industrial employment, and more than four-fifths of credit facilities were controlled by state-owned banking or financial institutions. Since that period successive right-wing and, more recently, left-of-centre governments have returned most enterprises to the private sector; state ownership is primarily concentrated in transport, defense, and broadcasting.

Improved living standards

Postwar economic growth has been accompanied by a substantial rise in living standards. As incomes have risen, proportionately less has been spent on food and clothing and more on items such as housing, transportation, health, and leisure. Workers' incomes are taxed at a high to moderate rate, and indirect taxation in the form of a value-added tax (VAT) is relatively high. Overall, taxes and social security contributions levied on employers and employees in France are higher than in many other European countries.

AGRICULTURE, FORESTRY, AND FISHING

France's extensive land area—of which more than half is arable or pastoral land and another quarter is wooded—presents broad opportunities for agriculture and forestry. The country's varied relief and soils and contrasting climatic zones further enhance this potential. Rainfall is plentiful throughout most of France, so water supply is not generally a problem. An ample fish supply in the Atlantic Ocean and Mediterranean Sea provides an additional resource.

Agriculture employs relatively few people—about 4 percent of the labour force—and makes only a small contribution to GDP—about 3 percent. Yet France is the EU's leading agricultural nation, accounting for more than one-fifth of the total value of output, and alone is responsible for more than one-third of the EU's production of oilseeds, cereals, and wine. France also is a major world exporter of agricultural commodities, and approximately one-eighth of the total value of the country's visible exports is related to agriculture and associated food and drink products.

Agricultural land use

France has a usable agricultural area of nearly 74 million acres (30 million hectares), more than three-fifths of which is used for arable farming (requiring plowing or tillage), followed by permanent grassland (about one-third) and permanent crops such as vines and orchards (about one-twentieth). Areas in which arable farming is dominant lie mostly in the northern and western regions of the country, centred on the Paris Basin. Permanent grassland is common in upland and mountainous areas such as the Massif Central, the Alps, and the Vosges, although it is also a notable feature of the western *région* of Basse-Normandie. Conversely, the major areas devoted to permanent cultivation lie in Mediterranean regions.

Grains. More than half of the country's arable land is used for cereals, which together provide about one-sixth of the total value of agricultural output. Wheat and corn (maize) are the main grains, with other cereals, such as barley and oats, becoming progressively less important. There are few areas of the country where cereals are not grown, although the bulk of production originates in the Paris Basin and southwestern France, where natural conditions and (in the former case) proximity to markets favour such activity. A considerable area (about one-seventh of the agricultural area), predominantly in western France, is also

Harvesting grapes in a vineyard at Ay, near Épernay, in the Champagne region.

given over to forage crops, although the acreage has been shrinking since the early 1980s as dairy herds have been reduced in accordance with EU guidelines. In contrast, there has been a substantial increase in oilseed output; the area under cultivation has quadrupled since the early 1980s and now approaches one-tenth of agricultural land.

Fruits and wine making. Vines, fruits, and vegetables cover only a limited area but represent more than one-fourth of the total value of agricultural output. France is probably more famous for its wines than any other country in the world. Viticulture and wine making are concentrated principally in Languedoc-Roussillon and in the Bordeaux area, but production also occurs in Provence, Alsace, the Rhône and Loire valleys, Poitou-Charentes, and the Champagne region. There has been a marked fall in the production of vin ordinaire, a trend related to EU policy, which favours an increase in the output of quality wines. Fruit production (mainly of apples, pears, and peaches) is largely concentrated in the Rhône and Garonne valleys and in the Mediterranean region. Vegetables are also grown in the lower Rhône and Mediterranean areas, but a large part of output comes from western France (Brittany) and the southwest and the northern *régions* of Nord–Pas-de-Calais and Picardy, where sugar beets and potatoes are produced.

Dairying and livestock. Cattle raising occurs in most areas of the country (except in Mediterranean regions), especially in the more humid regions of western France. Animal-related production accounts for more than one-third of the total value of agricultural output. In general, herds remain small, although concentration into larger units is increasing. Overall, however, the number of cattle has been falling since the early 1980s, largely as a result of EU milk quotas. These have adversely affected major production areas such as Auvergne, Brittany, Basse-Normandie, Pays de la Loire, Rhône-Alpes, Lorraine, Nord–Pas-de-Calais, and Franche-Comté. One result has been an increasing orientation toward beef rather than dairy breeds, notably in the area of the Massif Central. The raising of pigs and poultry, frequently by intensive methods, makes up more than one-tenth of the value of agricultural output. Production is concentrated in the *régions* of Brittany and Pays de la Loire, encouraged originally by the availability of by-products from the dairy industry for use as feed. Sheep raising is less important. Flocks graze principally in southern France on the western and southern fringes of the Massif Central, in the western Pyrenees, and in the southern Alps.

Reduction in cattle numbers

Agribusiness. Agriculture has changed in other ways. Farm structures have been modified substantially, and the number of holdings have been greatly reduced since 1955, numerous small farms disappearing. By the late 1990s there were fewer than 700,000 holdings, compared with more than 2,000,000 in the mid-1950s. The average size of farms has risen considerably, to nearly 100 acres (40 hectares). Large holdings are located primarily in the cereal-producing regions of the Paris Basin, while small holdings are most common in Mediterranean regions, the lower Rhône valley, Alsace, and Brittany. Important technical changes have also occurred, ranging from the increased use of intermediate products such as fertilizers and pesticides to the widespread use of irrigation (nearly one-tenth of agricultural land is now irrigated) and the growth of crops within controlled environments, such as under glass or plastic canopies. Marketing systems have also been modified, as an increasing proportion of output is grown under contract. Together such changes have led to a remarkable increase in output of major agricultural products, but they have also resulted in a large reduction in the number of agricultural workers and the increased indebtedness of many farmers, and the related negative effects on the environment have given rise to the organic farming movement.

Forestry. With more than 57,000 square miles of woodland, France possesses one of the largest afforested areas in western Europe, offering direct employment to more than 80,000 people. Forested areas are unevenly distributed, with the majority lying to the east of a line from Bordeaux to the Luxembourg border. Aquitaine and Franche-Comté have a particularly dense forest cover. This vast resource is, however, generally underexploited, partly because of the multitude of private owners, many of whom are uninterested in the commercial management of their estates. Less than one-fourth of the afforested area is controlled by the National Office of Forests.

Fishing. Despite the extent of France's coastlines and its numerous ports, the French fishing industry remains relatively small. Annual catches have averaged about 700,000 tons since the mid-1970s, and by the end of the 1990s there were fewer than 16,500 fishermen. The industry's problems are related to its fragmented character and to inadequate modernization of boats and port facilities, as well as to overfishing and pollution. Activity is now concentrated in the port of Boulogne in Nord–Pas-de-Calais and to a lesser degree in ports in Brittany such as Concarneau, Lorient, and Le Guilvinic. France is also known for its aquaculture, with activity increasing over recent years along the coastal waters of western France. Oyster beds are found particularly in the southwest, centred on Marennes-Oléron.

Major fishing ports

RESOURCES AND POWER

Compared with its agricultural resources, the country is far less well endowed with energy resources. Coal reserves are estimated at about 140 million tons, but French coal suffered from being difficult and expensive to mine and from its mediocre quality. In 1958 annual production amounted to some 60 million tons; 40 years later this total had dropped to less than 6 million tons, and in 2004 the last coal mine was shuttered. Consequently, imported coal long supplemented indigenous production and greatly exceeded domestic output. Imports originate mainly from Australia, the United States, South Africa, and Germany.

Other energy resources are in short supply. Natural gas was first exploited in southwestern France (near Lacq) in 1957. Production then increased substantially, only to decline after 1978 as reserves became exhausted. By the late 1990s, production was negligible, requiring a high level of imports, principally from the North Sea (Norway and The Netherlands), Algeria, and Russia. France has few oil reserves, and production from wells in Aquitaine and the Paris Basin is extremely limited. Uranium is mined in the Massif Central, and, although recoverable reserves are estimated at approximately 50,000 tons, more than half of the annual consumption has to be imported. France, however, does possess fast-moving rivers flowing out of highland areas that provide it with an ample hydroelectric resource.

Minerals. The metal industry is poorly supplied by indigenous raw materials, although traditionally France was an important producer of iron ore and bauxite. Iron ore output exceeded 60 million tons in the early 1960s, originating principally in Lorraine; but production has now ceased, despite the continued existence of reserves. Low in metal content and difficult to agglomerate, Lorraine ores were thus long supplemented and have now been replaced by richer overseas supplies from such countries as Brazil, Sweden, and Australia. Bauxite production is negligible, though other mineralized ores, such as those containing lead, zinc, and silver, are mined in very small quantities. Greater amounts of potash (mined in Alsace), sodium chloride (from mines in Lorraine and Franche-Comté and from salt marshes in western and southern France), and sulfur (derived from natural gas in Aquitaine) are produced, but again the trend is toward declining output as reserves are depleted. The supply of stone, sand, and gravel is relatively ubiquitous.

Energy. Through the post-World War II years, the increase in the demand for energy has closely followed the rate of economic growth. Thus, for much of the period until 1973, consumption increased rapidly. Then, in the wake of the two oil price rises of 1973 and 1979, demand stabilized, followed by a fall in the early 1980s until growth rates recovered after the mid-1980s.

The demand for different types of energy has changed considerably over time. In the early postwar years, coal provided the larger part of energy needs. By the 1960s, however, oil, as its price fell in real terms, was being used in ever-greater quantities, so that by 1973 about two-thirds of energy consumption was accounted for by crude oil. Since then a more diversified pattern of use has emerged. Coal now plays only a minor role, while the use of oil has also fallen, replaced partly by natural gas and notably by nuclear energy, which now accounts for more than one-third of primary energy consumption. One of the main consequences of these changes has been a reduction in the country's previously high dependence on external sources of supply.

Oil has long been France's principal energy import, which has led to the growth of a major refining industry, with plants concentrated in two areas of the lower Seine valley (Le Havre and Rouen) and in the region around Fos-sur-Mer and the Étang de Berre. Many markets are supplied with oil products by pipeline, which is also the distribution method for natural gas. Algerian imports arrive in the form of liquefied natural gas (primarily methane) and are unloaded at French ports where regasification plants operate.

Nuclear energy

Since the early 1980s one of the most significant changes in energy supply has been the greatly increased role of nuclear power, at the expense of fuel oil and coal; even the production of hydroelectric power has stabilized, as most suitable sites have already been exploited, particularly those of the Rhine and Rhône valleys, the Massif Central, and the Alps. In contrast, nuclear production, benefiting from major government investment from the early 1970s, expanded enormously in the 1980s, notably with the construction of sites in the Rhône and Loire valleys, a reflection of the need for large quantities of cooling water. By the late 1990s more than three-fourths of electricity in France was produced in nuclear plants, the highest proportion in the world, which enabled the country to become a large exporter of such energy. More recently development has slowed substantially, as demand has eased and environmental groups have campaigned against further investment. France's nuclear industry also includes a large uranium-enrichment factory at Pierrelatte in the lower Rhône valley and a waste-reprocessing plant at La Hague, near Cherbourg.

MANUFACTURING

Industrial trends. French industry was long the powerhouse of the country's postwar economic recovery. Yet, after a period of substantial restructuring and adjustment, particularly during successive periods of recession since the late 1970s, this sector (including construction and civil engineering) now employs only about one-fourth of the country's workforce and contributes the same proportion of GDP.

Changes in industrial location have also occurred. Industrial expansion in the 1960s and '70s was accompanied by large-scale decentralization, favouring many areas of the Paris Basin (where there was an abundant and relatively cheap supply of labour) at the expense of the capital. Few company headquarters followed the dispersion of manufacturing plants, however, so that the centre of industrial operations remained rooted in the Paris region. The decline of industrial employment since the mid-1970s has had the greatest impact in traditional manufacturing regions, such as Nord–Pas-de-Calais and Lorraine. Nevertheless, the broad arc of *régions* stretching through northern and eastern France, from Haute-Normandie to Rhône-Alpes, remains the most heavily industrialized part of the country.

The automobile industry

Branches of manufacturing. On the basis of employment and turnover, seven branches of manufacturing stand out as particularly important: vehicles, chemicals, metallurgy, mechanical engineering, electronics, food, and textiles. The vehicle industry is dominated by the activities of the two automobile manufacturers, Peugeot SA (including Citroën) and Renault, which together produced nearly four million cars annually at the beginning of the 21st century. Automobile production generates a substantial number of direct jobs as well as employment in subsidiary industries, such as the major tire manufacturer Michelin. France also possesses an important industry for the manufacture of railway locomotives and rolling stock, for which the expanding high-speed train (*train à grande vitesse*; TGV) network represents a major market.

Within the chemical industry, manufacturing ranges from basic organic and inorganic products to fine chemicals, pharmaceuticals, and other parachemical items, including perfumes. Because of the capital-intensive nature of these activities, a dominant role is played by large manufacturers such as Rhône-Poulenc. Extensive research is carried out in this field. Basic chemical production is concentrated in areas offering access to raw materials, such as Nord–Pas-de-Calais, Étang-de-Berre, and Rhône-Alpes, whereas pharmaceutical production is more closely related to major market areas and research centres, notably Île-de-France.

The metallurgical industry, dominated by the production of steel, experienced major restructuring in the late 1970s and the '80s as demand fell and competition from other international producers increased. Originally concentrated in Lorraine because of the presence of iron ore, steel production shifted to the coastal sites of Dunkirk and Fos-sur-Mer, which relied on imported ore and coal. France is also an important producer of aluminum, notably through the Pechiney group. Such basic metal industries support a diverse range of engineering activities, spread widely throughout France but with important concentrations in the highly urbanized and industrialized *régions* of Île-de-France and Rhône-Alpes. Similar features characterize the electrical engineering and electronics industries. France is a major manufacturer of professional electronics, such as radar equipment, but is weakly represented in the field of consumer electronics, which has led to a high level of imports. The country also has a number of high-tech aerospace industries, which manufacture aircraft, missiles, satellites, and related launch systems. These industries are concentrated in the Paris region and in the southwest around Toulouse and Bordeaux.

Food and beverage production

Food and beverage industries represent the largest branch of French manufacturing, reflecting the considerable volume and diversity of agricultural production. Although present in most regions, food manufacturers are particularly concentrated in major urban market areas and in western agricultural regions such as Brittany, Pays de la Loire, and Basse-Normandie. The beverage sector is dominant in the main wine-growing areas of northern and northeastern France; it represents an important source of exports.

Textile and clothing industries have experienced a long period of decline in the face of strong foreign competition, with substantial job losses and plant closures affecting the major production areas of northern France and Rhône-Alpes (textiles), as well as Île-de-France (clothing). Unlike other major industrial branches, these activities remain characterized by small firms.

A varied group of construction and civil engineering industries employs about one-fourth of the labour in the industrial sector. Activity and employment have fluctuated considerably in relation to changing government and private investment programs and the varying demand for new homes. This sector is characterized by the coexistence of a large number of small firms with a limited number of large companies, many of which work on civil engineering contracts outside France.

FINANCE

Growth of branch banking

Banking and insurance. France possesses one of the largest banking sectors in western Europe, and its four major institutions, Crédit Agricole, BNP-Paribas, Crédit Lyonnais, and Société Générale, rank among the top banks on the continent. Traditionally, banking activities were tightly controlled by the government through the Banque de France. However, deregulation beginning in the 1960s led to a substantial increase in branch banking and bank account holders, and legislation in 1984 further reduced controls over banks' activities, which thereby enabled them to offer a wider range of services and led to greater competition. Since then, encouraged by the lifting of restrictions on the free movement of capital within the EU in 1990, banks have broadly internationalized their activities. In 1993 the Banque de France was granted independent status, which freed it from state control. In general, employment in the banking sector has declined, largely because of the widespread computerization of transactions and this restructuring. At the turn of the 21st century, the franc gave way to the euro as the legal currency in France.

France has a large insurance industry dominated by major companies such as Axa, CNP, and AGF but also including a number of important mutual benefit societies, which administer pension plans. The deregulation of this sector has led to vast reorganization, with activity still concentrated in Paris though a number of provincial towns have developed as specialist centres through the location of various mutual societies.

The stock exchange. Share transactions in France are centred on the Bourse de Paris (Paris Stock Exchange), a national system that since 1991 has incorporated much smaller exchanges at Lyon, Bordeaux, Lille, Marseille, Nancy, and Nantes. Share dealings and stock market activity have increased greatly since the early 1980s, corresponding with a period of deregulation and modernization: official brokers lost their monopoly on conducting share transactions; a second market opened in 1983 to encourage the quotation of medium-size firms; and in 1996 the "new market" was launched to help finance young, dynamic companies in search of venture capital. Also in 1996 the Bourse was restructured, reinforcing the powers of its controlling body, Commission des Opérations de Bourse.

Foreign investment. Financial deregulation, the movement toward a single European market, and the general freeing of world trade are among the influences that have encouraged investment by French firms outside France and increased the reverse flow of foreign investment funds into the country. In the industrial field French companies have shown a growing interest in investing in other advanced economies, especially the United States. Over recent years investments have also multiplied in the developing economies of Asia and eastern Europe. Foreign firms investing in France have been principally from the EU (notably the United Kingdom, The Netherlands, and Germany) and the United States. Most investment is related to the fields of engineering, electronics, and chemicals and generally is directed at the more highly urbanized centres of the country. The sources and nature of foreign investment in France are becoming more diverse, however. Japanese interests have increased substantially, for instance, and investment in property and the service industry has been growing, particularly in and around Paris.

TRADE

France, a leading trading nation, has grown into one of the world's foremost exporting countries, with the value of exports representing more than one-fifth of GDP. France is also a major importer, especially of machinery, chemicals and chemical products, tropical agricultural products, and traditional industrial goods such as clothes and textiles. The high level of imports led to a trade deficit for much of the period between the early 1970s and early 1990s. However, from 1992 France experienced a trade surplus, combined with a positive balance from invisible (nonmerchandise) transactions, especially tourism.

Most foreign trade is based on the exchange of goods. In the case of agricultural commodities, France has become an increasingly important net exporter of raw agricultural products (such as grains) as well as agro-industrial products, such as foods and beverages, including wines, tinned fruits and vegetables, and dairy products. The need to import large quantities of oil (and to a lesser extent gas and coal), however, has resulted in a sizable deficit for those exchanges. Although France imports a great deal of industrial goods, the country has long been a major exporter of vehicles and transport equipment, as well as armaments and professional electronics. More recently exports of pharmaceuticals and parachemical products have risen.

Principal trading partners

The greater part of foreign trade is carried out with other developed countries, and some four-fifths of transactions take place with Organisation for Economic Co-operation and Development (OECD) countries. Among these the EU plays a major role, reflecting the growing exchange of goods and services between its member countries. More than three-fifths of French exports and imports are destined for or originate in EU countries, of which Germany is easily the most important. Outside the EU the United States is France's other major trading partner. EU countries are an important source of industrial imports, whereas fuel products and raw materials tend to originate from more distant sources. Conversely, agricultural and food exports are oriented predominantly toward European markets, whereas industrial goods are exported to a more global marketplace.

SERVICES

Tertiary-sector growth

The various service, or tertiary, industries in France account for about two-thirds of the country's employment and of GDP. These levels were reached following an extended period of sustained growth, notably since the 1960s. This sector covers a highly diverse range of activities, including social and administrative services, such as local government, health, and education; wholesaling, distribution, and transport and communication services; consumer services, such as retailing and the hotel and catering trades; and producer or business services, including banking, financial, legal, advertising, computing, and data-handling services.

Not all tertiary activities have developed in the same way. For example, rationalization in the banking and financial services sector has limited the creation of jobs. Conversely, the continuously strong growth, since the early 1970s, of hypermarkets and other large frcestanding retail outlcts that allow for purchasing in bulk and in greatcr variety has led to a significant rise in related employment. In particular the large group of producer services has expanded rapidly. In part this trend is the inevitablc consequence of the increasingly complex and highly competitivc nature of the modern economy. It also results from companies' strategies of externalizing (outsourcing) such service rcquircments for reasons of efficiency and cost savings.

Central-ization in Paris

Tertiary activities are located predominantly in urban areas, especially the larger citics. Such concentration is most evident in relation to thc capital. The Île-dc-France *région* surrounding Paris accounts for ncarly one-fourth of all tertiary employment alone, despite containing less than one-fifth of the population. In Paris the scctor's importance is qualitative as well as quantitative. Paris houscs more than two-thirds of the headquarters of the country's major companies and a disproportionatcly largc share of senior managcment and rcsearch staff. This attraction to the capital is influenced by a numbcr of factors, including the size and diversity of the labour market, thc high level of accessibility to other French and international business centres, prestige, and the prcsence of numerous spccialized services.

Civil service. The largest groups of employces are those in national education and thc postal systcm. As in the judicial system, French administration has bccn strongly marked by a strict hierarchy since the time of Napolcon. Civil servants are grouped into diffcrent corps and different ranks and are classified according to their rccruitmcnt level into four different categories. Entry is by a compctitive examination. At the highest level, category A civil servants are recruited through a national school of administration, created in 1945, which gives access to the *grands corps de l'État*, including the Court of Accounts, the Inspection of Finance, the prcfectural corps, the diplomatic service, and the civil administrators' corps. The duties and rights of civil servants are defined by a general statute of 1946, which was partly modified in 1959. The career guarantees and disciplinary code are extensive and are protected by the Conseil d'État (Council of State). In return, civil servants are duty-bound to be discreet in expressing any personal opinions, and the right to strike, which is recognized by the constitution for all French citizens, is severely limited for them, although this varics according to the corps. Most civil servants belong to labour unions.

Tourism. With France's variety of landscapes and climatic conditions, its cultural diversity, and its renowned cuisine, it is of little surprise that tourism should have become a major industry. Directly and indirectly this activity employs about 7 percent of the workforce and contributes approximately 8 percent of GDP, earning French businesses a substantial income from foreign visitors and more than compensating for the amount spent by French tourists abroad. France is one of the world's leading tourist destinations, visited by up to 70 million foreign tourists each year at the end of the 20th century.

The tourist industry has grown rapidly since the 1960s, with an increasingly large number of French families taking a holiday each year, encouraged by greater affluence, more leisure time, and, since 1982, five weeks' statutory paid holiday. In response to this increase in demand, the industry itself has changed. An activity traditionally distinguished by small businesses has been transformed by the growth of increasingly large hotel and holiday firms; new resorts have been built, notably along the Languedoc and Aquitaine coasts and in the French Alps, and new tourist products have been developed, including spectacular theme parks. The Disneyland complex on the eastern fringe of Paris, which opened in 1992, epitomized this trend.

Comparatively few French people take their holidays abroad. Conversely, France receives a large influx of foreign visitors, mainly from European countries, especially Germany. The unequal impact of tourism on different regions is a key feature of this activity. In summer a restricted number of coastal areas, notably in the Midi and in Brittany, receive the heaviest influx of holidaymakers; in winter mountainous regions become the preferred destination, particularly the northern Alps, with such major ski resorts as Chamonix, Tignes, La Plagne, and Les Arcs. Paris itself is an enormous tourist attraction, especially for foreign visitors and for events such as exhibitions and conferences; indeed, the capital is perhaps the world's leading centre for international conferences.

LABOUR AND TAXATION

Structural changes in the economy have helped transform the French labour force. Since the 1960s there has been a growing transfer from blue- to white-collar occupations, particularly as jobs in management, the professions, and administration have greatly increased. This change has been accompanied by a marked rise in female employment, so that almost half of all jobs are now held by women. A significant increase in part-time work and employment on fixed-term contracts has also taken place for both sexes. Firms have favoured this development because of the greater flexibility it offers, as have employees themselves, seeking freer, less-formalized working arrangements. The trend has also been encouraged by short-term government measures to reduce unemployment.

Such changes away from standard jobs have also contributed to the weakened position of trade unions in France: as little as one-tenth of French workers belong to a union. Traditional support from blue-collar workers has also been eroded by heavy job losses in industries such as steel, shipbuilding, and vehicles. The main trade unions are the General Confederation of Labour, Force Ouvrière (literally "workforce"), and French Democratic Confederation of Labour. With the exception of those in 1968, major nationwide strikes have been relatively infrequent in France. Employers, for their own part, are grouped together within the Movement for French Enterprises (Mouvement des Entreprises de France), which in 1998 replaced the National Council of French Employers (Conseil National du Patronat Français). This organization represents all firms in negotiations with the government, state administrative services, and unions.

TRANSPORTATION AND TELECOMMUNICATIONS

The transportation sector includes such dynamic companies as the National Society of French Railways (Société Nationale des Chemins de Fer Français), the state-owned railways operator, and Air France, the national airline. Closely allied are manufacturers of transport equipment and the civil engineering concerns responsible for constructing new infrastructure. Generally, France benefits from a dense and diversified transport network, limited only by its still excessive focus upon the capital city. For land-based movements the road network has become increasingly important. For example, a vast majority of all freight traffic, in terms of the volume and distance of goods moved, goes by road. This dominance has been achieved at the expense of railways and inland waterways.

Growth of highway traffic

Roads. Traffic on the highways has more than doubled since 1970, and about one-fifth of vehicles are commercial. An extensive road system totaling about 600,000 miles has been developed to deal with increasingly heavy traffic conditions. However, only a small proportion of this network consists of main trunk roads (the *routes nationales*) and motorways. Construction on the latter began much later than in neighbouring countries, and it was not until the mid-1960s that a major development program was under way. To speed progress, building concessions were granted to private and semiprivate companies, which, in return for their investment, were authorized to levy tolls. Since that period the major radial routes from the capital have been completed, as have embryonic regional networks focusing on large urban centres, such as Paris, Lyon, Marseille, and Lille. Traffic is heavily concentrated on the main north-south axis between these cities. In extending the system, emphasis has been placed on improving international links and developing national routes that avoid Paris, as between Calais and Dijon, as well as Bordeaux and Clermont-Ferrand. Numerous rural roads and lanes supplement the main system.

Railroads. By the end of the 19th century, the present rail network was largely in place, dominated by the main lines radiating from Paris. Since World War II many little-used rural sections have been closed. In contrast, since the early 1980s certain new lines have been opened in conjunction with the introduction of high-speed passenger trains (*trains à grande vitesse*; TGV) between Paris and a number of provincial cities. Southeastern France was the first area to be provided with such services, reflecting the already high density of traffic between Paris, Lyon, and the Mediterranean coast. New lines are also in operation to western and northern France, with longer-term plans to serve eastern regions. International service also exists to Geneva, Lausanne, and Brussels, as well as to London, by means of the Channel Tunnel, which opened in 1994 after six years of construction. It is used for passenger and freight trains as well as for transporting cars and commercial vehicles. By the end of the 20th century, the Eurostar passenger trains linked Paris to London in three hours and carried more than seven million travelers annually. In France the TGV network alone accounts for more than one-half of passenger miles and has attracted many new customers to the railways. Generally, however, fewer than one-fifth of passenger movements in France were accounted for by rail services, with traffic heavily concentrated along the main, electrified radial routes from the capital, particularly in the direction of southeastern France. Freight traffic has declined, partly because of fallen demand for products such as coal, iron, and oil, traditionally carried by rail, and partly because of intense competition from road haulers. Like passenger traffic, freight movements are concentrated along the main radial routes, as well as along the lines linking the industrial centres of northern and northeastern France.

Decline of rail freight traffic

Within an increasing number of urban areas, investment has been made in new underground rail and tram systems in an effort to reduce congestion on the roads and related problems of pollution. Provincial cities such as Lyon, Marseille, Lille, and Toulouse now boast metro networks, while a growing number of other cities (such as Lille, Nantes, Strasbourg, and Grenoble) are served by tramways, a solution increasingly favoured because of its comparatively lower cost. However, this has not stopped further substantial investment in the Paris Métro or the high-speed regional system (Réseau Express Régional; RER). Lines have been extended farther into the suburbs, and major new capacity has been added in central Paris.

Waterways. Despite the presence of major rivers such as the Seine, Rhine, and Rhône, inland waterways carry little freight. Although they are still used to transport goods

A high-speed TGV (*train à grande vitesse*) traversing the Burgundy region between Tournous and Mâcon.

such as construction materials and agricultural and oil products, their role has progressively declined in the face of cheaper and faster alternatives. Traffic has also been lost because of the reduced inland movement of heavy raw materials and fuel products and an inefficiently organized industry with too many small-barge operators. The uneven and disjointed pattern of the waterways further restricts use. Less than one-third of the commercial waterway system is of European standard gauge; moreover, the principal river and canal systems remain unconnected for the passage of large barges, so that no truly national or international network exists.

France is served by a large number of maritime ports, which reflects not only its extensive coastline but also its importance as a trading nation. As in other Western countries, however, France's merchant fleet has steadily shrunk, largely because of the difficulty of competing with lower-cost carriers. Freight traffic, consisting mostly of imports, is concentrated in a limited number of ports, principally Marseille and Le Havre, followed by Dunkerque, Calais, Nantes-Saint-Nazaire, and Rouen. This imbalance is partly explained by the still-sizable quantities of crude oil that are unloaded. Passenger traffic is less important but is dominated by cross-channel movements from the port of Calais and the nearby Channel Tunnel.

Air transport. Air freight and passenger traffic have expanded rapidly and, like other forms of transport, are centred on Paris. The capital's two major airports (Roissy [Charles de Gaulle] and Orly) represent the second largest airport complex in western Europe (after London), handling roughly two-thirds of all French passenger traffic. Other French airports are far less important, though the country has a comprehensive network of local and regional airports. The majority of routes, however, are between provincial towns and cities and the capital rather than between regional centres, which reemphasizes the persistent centralization of economic activity and decision making in France. Nice and Marseille are the busiest regional air centres and, along with Lyon, Bordeaux, Toulouse, and Strasbourg, are the only provincial airports to have significant international traffic.

Telecommunications. At the beginning of the 21st century, France had some 34 million main telephone lines, almost all with digital capacity. Nevertheless, the nation lagged behind many EU countries in telecommunications in that just over half of its citizens used cellular telephones, only about one-third owned personal computers, and roughly one-sixth were Internet users. These comparatively low statistics were due in part to restrictive government controls on electronic commerce (e-commerce) and the presence of an existing network called Minitel (founded 1983 and owned by France Telecom)—obstacles that began to fall away in the first years of the 21st century. (J.N.T./Ed.)

Government and society

CONSTITUTIONAL FRAMEWORK

The genesis of the 1958 constitution. When France fell into political turmoil after the May 1958 insurrection in Algeria (then still a French colony), General Charles de Gaulle, an outspoken critic of the postwar constitution who had served as the provisional head of government in the mid-1940s, returned to political life as prime minister. He formed a government and, through the constitutional law of June 1958, was granted responsibility for drafting a new constitution. The drafting of the constitution of the Fifth Republic and its promulgation on Oct. 4, 1958, differed in three main ways from the former constitutions of 1875 (Third Republic) and 1946 (Fourth Republic): first, the parliament did not participate in its drafting, which was done by a government working party aided by a constitutional advisory committee and the Council of State; second, French overseas territories participated in the referendum that ratified it on Sept. 28, 1958; and, third, initial acceptance was widespread, unlike the 1946 constitution, which on first draft was rejected by popular referendum and then in a revised form was only narrowly approved. In contrast, the 1958 constitution was contested by 85 percent of the electorate, of which 79 percent were in favour; among the overseas territories only Guinea rejected the new constitution and consequently withdrew from the French Community.

Earlier constitutions

The dual executive system. In order to achieve the political stability that was lacking in the Third and the Fourth Republic, the constitution of 1958 adopted a mixed (semi-presidential) form of government, combining elements of both parliamentary and presidential systems. As a result, the parliament is a bicameral legislature composed of elected members of the National Assembly (lower house) and the Senate (upper house). The president is elected separately by direct universal suffrage and operates as head of state. The constitution gives the president the power to appoint the prime minister (often known as the premier), who oversees the execution of legislation. The president also appoints the Council of Ministers, or cabinet, which together with the prime minister is referred to as the government.

The role of the president. The French system is characterized by the strong role of the president of the republic. The office of the president is unique in that it has the authority to bypass the parliament by submitting referenda directly to the people and even to dissolve the parliament altogether. The president presides over the Council of Ministers and other high councils, signs the more important decrees, appoints high civil servants and judges, negotiates and ratifies treaties, and is commander in chief of the armed forces. Under exceptional circumstances, Article 16 allows for the concentration of all the powers of the state in the presidency. This article, enforced from April to September 1961 during the Algerian crisis, has received sharp criticism, having proved to be of limited practical value because of the stringent conditions attached to its operation.

De Gaulle's great influence and the pressures of unstable political conditions tended to reinforce the authority of the presidency at the expense of the rest of the government. Whereas the constitution (Article 20) charges the government to "determine and direct" the policy of the nation, de Gaulle arrogated to himself the right to take the more important decisions, particularly concerning foreign, military, and institutional policies, and his successors adopted a similar pattern of behaviour. The constitution of 1958 called for a presidential term of seven years, but, in a referendum in 2000, the term was shortened to five years, beginning with the 2002 elections.

The role of the prime minister, however, has gradually gained in stature. Constitutionally, the office is responsible for the determination of governmental policy and exercises control over the civil service and the armed forces. Moreover, while all major decisions tended to be taken at the Élysée Palace (the residence of the president) under de Gaulle, responsibility for policy, at least in internal matters, has slowly passed to the head of the government. Especially since the mid-1970s, a working partnership between the president and the prime minister has tended to be established. Finally, the power of the president is tied to the parliamentary strength of the parties that support him and that form a majority in the National Assembly. It is possible, however, for the president's parties to become a minority in the assembly, in which case the president must appoint a prime minister from the majority faction. From 1986 through the beginning of the 21st century, except for two years (1993–95), France experienced a form of divided government known as "cohabitation," in which the president and the prime minister belonged to different parties.

The National Assembly and the Senate

Parliamentary composition and functions. The National Assembly is composed of 577 deputies who are directly elected for a term of five years in single-member constituencies on the basis of a majority two-ballot system, which requires that a runoff take place if no candidate has obtained the absolute majority on the first ballot. The system was abandoned for proportional representation for the 1986 general election, but it was reintroduced for the 1988 election and has remained in place ever since. The Senate is composed of 321 senators indirectly elected for nine years by a *collège électoral* consisting mainly of municipal councillors in each *département*, one of the administrative units into which France is divided. The parliament retains its dual function of legislation and control over the executive but to a lesser extent than in the past. The domain of law (Article 34) is limited to determining the basic rules and fundamental principles concerning such matters as civil law, fiscal law, penal law, electoral law, civil liberties, labour laws, amnesty, and the budget. In these matters the parliament is sovereign, but the government can draw up the details for the application of laws.

The government is responsible for all other matters, according to Article 37 of the constitution, and the assemblies can in no way interfere; the Constitutional Council is responsible for ensuring that these provisions are respected. The parliament can temporarily delegate part of its legislative power to the government, which then legislates by ordinances. This procedure has been used on matters concerning Algeria, social security, natural disasters, European integration, and unemployment. Finally, government and the parliament are advised by an Economic and Social Council, composed of 230 representatives of various groups (*e.g.*, trade unions and employers' and farmers' organizations) that must be consulted on long-term programs and on developments and that may be consulted on any bill concerning economic and social matters.

The right to initiate legislation is shared by the government and the parliament. Bills are studied by parliamentary committees, although the government does control the agenda. The government can also, at any point during the debate over a bill, call for a single vote on the whole of the bill's text. Parliamentary control over the government can be exercised, but it is less intense than in the British system. There are questions to ministers challenging various aspects of performance, but these take place infrequently and are primarily occasions for lesser debates and do not lead to effective scrutiny of the government's practices. Committee inquiries are also relatively rare. The National Assembly, however, has the right to censure the government, but, in order to avoid the excesses that occurred before 1958 (as a result of which governments often fell once or twice a year), the motion of censure is subject to considerable restrictions. Only once in the first 50 years of the Fifth Republic, in 1962, did the National Assembly pass a motion of censure, when it stalled de Gaulle's referendum for direct election of the president by universal suffrage, which ultimately met with approval. The government is also strengthened by its constitutional power to ask for a vote of confidence on its general policy or on a bill. In the latter case a bill is considered adopted unless a motion of censure has obtained an absolute majority.

The motion of censure

The role of referenda. The people may be asked to ratify, by a constituent referendum (Article 89), an amendment already passed by the two houses of the parliament. The constitution made provision for legislative referenda, by which the president of the republic has the authority to submit to the people a proposed bill relating to the general organization of the state (Article 11).

This procedure was used twice in settling the Algerian question of independence, first in January 1961, to approve self-determination in Algeria (when 75 percent voted in favour), and again in April 1962, approving the Évian Agreement, which gave Algeria its independence from France (when 91 percent voted in favour). The use of this latter procedure to amend the constitution without going through the preliminary phase of obtaining parliamentary approval is constitutionally questionable, but it led to a significant result when, in October 1962, the election of the president by universal suffrage was approved by 62 percent of those voting. In April 1969, however, in a referendum concerning the transformation of the Senate into an economic and social council and the reform of the regional structure of France, fewer than half voted in favour, and this brought about President de Gaulle's resignation.

Through the end of the 20th century, national referenda were met with low voter turnout. The procedure was used in 1972 for the enlargement of the European Economic Community (EEC; later the European Community, which became part of the EU) by the proposed addition of Denmark, Ireland, Norway, and the United Kingdom; in 1988 for the proposed future status of the overseas territory of New Caledonia; and in 1992 for approval of the Maastricht Treaty, which established the EU. In 1995, when minor modifications were made to the constitution, the use of the referendum was enlarged to include proposed legislation relating to the country's economic and social life. In 2000 a referendum shortened the presidential term from seven to five years.

The role of the Constitutional Council. The Constitutional Council is appointed for nine years and is composed of nine members, three each appointed by the president, the National Assembly, and the Senate. It supervises the conduct of parliamentary and presidential elections, and it examines the constitutionality of organic laws (those fundamentally affecting the government) and rules of parliamentary procedure. The council is also consulted on international agreements, on disputes between the government and the parliament, and, above all, on the constitutionality of legislation. This power has increased over the years, and the council has been given a position comparable to that of the U.S. Supreme Court.

REGIONAL AND LOCAL GOVERNMENT

The units of local government are the *régions*, the *départements*, the *communes*, and the overseas territories.

Establishment of the *régions*

The *régions*. One of the main features of decentralization in French government has evolved through the creation of the 22 *régions*. After a number of limited changes lasting two decades, a 1982 law set up directly elected regional councils with the power to elect their executive. The law also devolved to the regional authorities many functions hitherto belonging to the central government, in particular economic and social development, regional planning, education, and cultural matters. The *régions* have gradually come to play a larger part in the administrative and political life of the country.

The *départements*. The *région* to an extent competes with the *département*, which was set up in 1790 and is still regarded by many as the main intermediate level of government. By the late 20th century, the initial number of 83 *départements* had reached 100: 96 in metropolitan France and 4 overseas (Guadeloupe, Martinique, French Guiana, and Réunion). Each *département* is run by the General Council, which is elected for six years with one councillor per *canton*. There are between 13 and 70 *cantons* per *département*. The General Council is responsible for all the main departmental services: welfare, health, administration, and departmental employment. It also has responsibility for local regulations, manages public and private property, and votes on the local budget. A law passed in 1982 enhanced decentralization by increasing the powers and authority of the *départements*. Formerly, the chief executive of the *département* was the government-appointed prefect (*préfet*), who also had strong powers over other local authorities. Since the law went into effect, however, the president of the General Council is the chief executive and the prefect is responsible only for preventing the actions of local authorities from going against national legislation.

The *communes*. The *commune*, the smallest unit of democracy in France, dates to the parishes of the ancien régime in the years before the Revolution. Its modern structure dates from a law of 1884, which stipulates that *communes* have municipal councils that are to be elected for six years, include at least nine members, and be responsible for "the affairs of the *commune*." The council administers public land, sets up public undertakings, votes on its own budget, and over recent years has played an increasing role in promoting local economic development. It elects a mayor and the mayor's assistants. Supervision by the central government, once very tight, has been markedly reduced, especially since 1982.

The importance of the mayor

The mayor is both the chief executive of the municipal council and the representative of the central government in the *commune*. The mayor is in charge of the municipal police and through them ensures public order, security, and health and guarantees the supervision of public places to prevent such things as fires, floods, and epidemics. The mayor also directs municipal employees, implements the budget, and is responsible for the registry office. French mayors are usually strong and often dominate the life of the *commune*. They are indeed important figures in the political life of the country.

French *communes* are typically quite small; there are more than 36,500 of them. Efforts have been made to group *communes* or to bring them closer to one another, but these have been only partly successful. In certain cities, such as Lyon and Lille, cooperative urban communities have been created to enable the joint management and planning of a range of municipal services, among them waste disposal, street cleaning, road building, and fire fighting. A similar approach has been adopted elsewhere, including rural areas, with the establishment of *syndicats intercommunaux* that allows services to be administered jointly by several *communes*. Moreover, since the 1999 law on Regional Planning and Sustainable Development, the *communes* within urban areas of more than 50,000 inhabitants have been encouraged to pool resources and responsibilities to promote joint development projects by means of a new form of administrative unit known as the *communauté d'agglomération*.

• **The overseas territories.** The status of many of France's overseas territories—vestiges of the French Empire—changed in the 1970s. Independence was proclaimed in 1975 by the Indian Ocean archipelago of the Comoros, with the exception of Mayotte (Mahoré) island, which chose to remain within French rule; in 1977 by Djibouti, on the Horn of Africa; and in 1980 by the Anglo-French Pacific Ocean condominium of the New Hebrides, under the name of Vanuatu. Mayotte was elevated to the status of territorial collectivity in 1976, and in North America the island territory of Saint-Pierre and Miquelon was elevated to the same status in 1985.

The only places retaining overseas territory status are French Polynesia (with its capital at Papeete on the island of Tahiti), New Caledonia, the Wallis and Futuna islands in the Pacific, and the Adélie Land claim in Antarctica. These territories have substantial autonomy except in matters reserved for metropolitan France, such as diplomacy and defense. They are governed through various but similar administrative structures, usually involving an elected council and a chief executive, but they are subject to the tutelage of a representative of the French Republic. A 1998 decision regarding New Caledonia envisaged the progressive transfer of political responsibilities to the island over a period of 15 to 20 years. Following decades of separatist violence, the overseas territory of Corsica was granted greater autonomy in the first years of the 21st century.

JUSTICE

In France there are two types of jurisdictions: the judiciary that judges trials between private persons and punishes infringements of the penal law and an administrative judicial system that is responsible for settling lawsuits between public bodies, such as the state, local bodies, and public establishments, as well as private individuals.

Civil courts

The judiciary. For civil cases the judiciary consists of higher courts (*grande instance*) and lower courts (*tribunaux d'instance*), which replaced justices of the peace in 1958. For criminal cases there are *tribunaux correctionnels* ("courts of correction") and *tribunaux de police*, or "police courts," which try minor offenses. The decisions of these courts can be referred to one of the 35 courts of appeal. Felonies are brought before the assize courts established in each *département*, consisting of three judges and nine jurors.

All these courts are subject to the control of the Court of Cassation, as are the specialized professional courts, such as courts for industrial conciliation, courts-martial, and, from 1963 to 1981, the Court of State Security, which tried felonies and misdemeanours against national security. Very exceptionally, in cases of high treason, a High Court of Justice (Cour de Justice de la République), composed of members of the National Assembly and of senators, is empowered to try the president of the republic and the ministers. They can also be tried by this court if they have committed felonies or misdemeanours during their term of office. These are the only situations in which the Court of Cassation is not competent to review the case. Otherwise, the court examines judgments in order to assess whether the law has been correctly interpreted; if it finds that this is not the case, it refers the case back to a lower court.

The more than 5,000 judges arc recruitcd by means of competitive examinations hcld by the National School of the Magistracy, which was founded in 1958 and in 1970 replaced the National Centre for Judicial Studies. A traditional distinction is made between thc *magistrats du siège*, who try cases, and the *magistrats de parquet* (public prosecutors), who prosecute. Only the former enjoy the constitutional guarantee of irremovability. The High Council of thc Judiciary is made up of 20 members originally appointed by the head of state from among the judiciary. Since 1993, however, its members have been elected, following reforms designed to free the judiciary from political control. The Council makes proposals and gives its opinion on the nomination of the *magistrats du siège*. It also acts as a disciplinary council. Public prosecutors act on behalf of thc statc. Thcy are hierarchically subject to the authority of the ministcr of justice. Judges can serve successively as members of the bench (*siège*) and the public prosecutor's department. They act in collaboration with, but are hierarchically independent of, the police.

Administrative courts. One of the special characteristics of the French judicial system is the existcnce of a hierarchy of administrative courts whose origins date to Napoleon. The duality of the judicial system has been sometimes regarded unfavourably, but the system has come to be gradually admired and indeed widely adopted in continental European countries and in the former French colonies. The administrative courts are undcr the control of the Council of State, which examines cases on appeal. The Council of State thus plays a crucial part in exercising control over the government and the administration from a jurisdictional point of view and ensures that they conform with the law. It is, moreover, empowered by the constitution to give its opinion on proposed bills and on certain decrees.

POLITICAL PROCESS

Universal suffrage at age 21 has existed in France since 1848 for men and since 1944 for women; the age of eligibility was lowered to 18 in 1974. Legislation enacted in the late 1990s penalizes political parties for failing to maintain sufficient parity between male and female candidates. Candidates for the National Assembly must receive a majority, not a plurality, of votes, and, if no candidate receives an absolute majority, then a second ballot is held the following week and the post is awarded to the plurality winner. Elections follow the model of single-member districts rather than proportional representation within a district. Two-phase voting is also used for the presidency, with the exception that, if an absolute majority is not reached after the first ballot, then only the two highest vote getters are considered for the second ballot, which is contested two weeks later.

Historically, French political parties have been both numerous and weak, which is generally accepted as the reason governments fell frequently before the advent of the Fifth Republic in 1958. Since then there has been a degree of streamlining, although, especially among centrist groups, parties are still poorly organized and highly personalized. Indeed, there have been many vicissitudes in the fortunes of the main parties since the late 1950s. In the 1960s and early '70s, Charles de Gaulle's centre-right party—first named Union for the New Republic (UNR) and later Rally for the Republic (RPR)—dominated the elections. After the election of the centrist Valéry Giscard d'Estaing to the presidency in 1974, the Gaullist party declined, while the centrists (from 1978 as the Union for French Democracy; UDF) and Socialists gained in strength. From 1981, and with the election of the Socialist president François Mitterrand, the Socialist Party became dominant, with its gains made primarily at the expense of the Communists. It was the first time since 1958 that the left had taken the leadership in French politics. While the Gaullists achieved a comeback with the election of Édouard Balladur as prime minister in 1993 and of Jacques Chirac as president in 1995, the Socialists regained control of the government in 1997 when Lionel Jospin became prime minister. In 2002 Chirac was reelected to the presidency under the coalition banner of the Union for Presidential Majority, decisively putting down Jean-Marie Le Pen of the far-right National Front, who surprised many with his strong showing in the first round of balloting. Chirac named Jean-Pierre Raffarin as his prime minister.

The French party system has continued to display volatility, though less so than in the past. Because the dominance of the Gaullist party was relatively short-lived, with other groups from the centre eroding its strength, the parliamentary base of the governments of the centre-right shrank; this was especially so since the centrists remained a loose confederation of several groupings, each of which tended to adopt different tactics. The precarious nature of political balance was underscored by recent periods of cohabitation between presidents and prime ministers of opposing parties.

SECURITY

Armed forces. The overall responsibility for national defense rests with the president, who is the constitutional chief of the armed services and presides over the higher councils and committees on national defense. Since a decree in 1964, the president can give the order to bring the air and strategic forces into action. The prime minister, assisted by the secretary-general for national defense, oversees the armed forces according to the terms of the constitution, but it is the minister of defense who actually directs the land, air, and naval forces and who, moreover, has authority over the armament policy and the arsenal.

Since 1958 the military administration has been divided by various functions; it includes strategic nuclear forces, territorial-defense forces, mobile forces, and task forces. France has had the atomic bomb since 1960 and the hydrogen bomb since 1968. The nation withdrew from the integrated command of the North Atlantic Treaty Organization (NATO) in 1966 but rejoined in 1995. An all-volunteer army was in place by 2002, though previously every French male 18 years of age had been subject to one year of compulsory military service.

Nuclear weapons

Police services. The police are responsible primarily for maintaining public law and order. Under the authority of the minister of interior, they are responsible to the prefects in the *départements* and to the prefect of police in Paris and adjacent suburban *communes*. The police force is divided into public security forces and specialized police forces, such as the vice squad. The security police include the State Security Police (Compagnies Républicaines de Sécurité; CRS), responsible for public order; the judicial police, who carry out criminal investigations and hunt down suspects; and the complex internal intelligence and antiespionage units. The municipal forces are responsible to the mayor. There is also the national gendarmerie, a kind of state police, which is responsible to the minister of defense, combats terrorism, and is of particular importance in the rural areas.

The gendarmerie

HEALTH AND WELFARE

Social security and health. Almost everyone is covered by the social security system, notably after the reform of 1998 that extended coverage to those previously excluded owing to lack of income. Social insurance was introduced in 1930 and family allowances in 1932, but the comprehensive rules for social security were established in 1946. A network of elected social security and family allowance *caisses primaires* ("primary boards"), headed by national *caisses*, manages a considerable budget. This budget relies on employers' and employees' social security contributions, as well as the proceeds from a special tax, introduced in 1991 (*contribution sociale généralisée*), on all forms of income. Deficits are made up by the state. The majority of expenditure is devoted to retirement benefits (pensions) and the partial reimbursement of most medical expenses. Other payments include family benefits for dependent children, unemployment indemnities, and housing subsidies. Since 1988, in response to a long-term problem of unemployment in France, people with little or no income have been able to benefit from a special government subsidy known as the social minimum (*revenu minimum d'insertion*).

France complies with the principles of liberal medicine, with patients free to choose doctors and treatment. Since 1960, however, agreements have been signed at a regional level between the *caisses* and the professional medical associations that regulate fees. Although doctors need not necessarily adhere to them, reimbursements from social security are based on these scales.

Hospital reforms

The hospital reform of 1960 joined hospitals and medical schools through the creation of teaching hospitals. Private hospitals and clinics operate alongside public hospitals, and the cost of treatment in private facilities may also be partially reimbursed from social security funds. Since the enactment of legislation in 1991, the government has sought to rationalize the distribution of hospitals to take advantage of shifting population densities, changing health care needs, and new technology.

Housing. The government encourages construction through premiums, loans (particularly for low-rent housing), and tax incentives. Municipal and other public bodies also have engaged in a vast program of subsidized public housing (*habitation à loyer modéré*; HLM), which was especially prominent in the 1960s and '70s. In 1970 the procedure for receiving building permits for private construction was greatly simplified, and since 1982 mayors have been responsible for granting construction permits and devising local housing policies for both the public and private sectors. The government has also sought to encourage home ownership through low-interest loans. As a result of continuing suburbanization, far greater emphasis is now placed on building houses rather than apartments. From the late 1960s city planning in France became more organized through such programs as *zone d'aménagement concerté* (ZAC), which often link both private and public developers. Reforms in 2000 updated long-term development plans (*schéma de cohérence territoriale*; SCOT) and detailed land-use plans (*plan local d'urbanisme*; PLU). The current emphasis of urban policy is on rehabilitation, particularly of the many peripheral housing estates built in the 1960s and '70s but also of older central districts.

Wages and the cost of living. Despite a history of high inflation, over recent years levels have been similar to those of other industrialized countries. Indeed, since the mid-1980s inflation has been particularly low in France. A minimum wage law has been in effect since 1950, and since 1970 it has been supplemented by a provision known as the *salaire minimum interprofessionel de croissance* (SMIC; general and growth-indexed minimum wage), which has increased the lowest salaries faster than the inflation rate. Its level is set annually, and all employers must abide by it. Women are, in general, paid less well than men. A worker earns nearly twice as much in Paris as in the less-developed *départements* of central France. The differentials between the earnings of manual workers and those of managers, while still large, have diminished progressively. In general, the majority of French society has benefited from a very substantial increase in purchasing power over the last half century.

EDUCATION

The organization of national education is highly centralized. Since 1968, however, following rioting among university students seeking a greater voice in their administration, a movement toward decentralization has been in progress in higher education. Reforms have sought to modify the character and structure of education, not only at the university level but also in primary and secondary schools; in the latter case one of the principal government aims has been to enable 80 percent of secondary-school students to obtain their *baccalauréat*.

France has both public and private education. All public education is free and is administered by the Ministry of National Education, which draws up the curricula, employs the staff, and exercises its authority through rectors placed at the heads of academies. However, while the state retains control of the educational programs and faculty, responsibility for the provision and maintenance of schools has been decentralized since the early 1980s; the *communes* look after primary schools, while in secondary education the *départements* are responsible for the *collèges* and the *régions* maintain the *lycées*.

Primary and secondary education. Education is free and compulsory between ages 6 and 16. Children under age 6 can attend *écoles maternelles* (nursery schools). Primary schools provide elementary education for those between ages 6 and 11. Secondary education begins in the *collèges* from ages 11 to 15 with further secondary education offered in general or technical *lycées*, leading to the national *baccalauréat* examination. Courses of study lasting for two or three years can lead to professional certificates or diplomas. School councils allow teachers and representatives of parents (and pupils at the secondary level) to gather to discuss the operation of schools.

Decentralization

Higher education. Following the student riots of May 1968, higher education was profoundly changed with the enactment of reforms on Nov. 12, 1968, though many centralizing features from the past remain. Previously, universities had been divided into faculties or colleges according to the subjects taught. After 1968 the faculties were replaced by teaching and research units regrouped into autonomous multidisciplinary universities comanaged by representatives elected from among the teaching staff, students, and administration. These institutions substantially determine their own research programs, teaching methods, and means of assessment. Much of the curriculum is still validated at the national level, however.

The state grants funds to the universities, which they divide among their departments. The degrees awarded are the *licence* (roughly comparable to the British-American bachelor's degree), *maîtrise* (master's degree), and doctorate. There are also special teaching qualifications, one of which is the *agrégation*, a rigorous competitive examination. Traditional university courses were considerably diversified by the creation of specialized technological sections (Instituts Universitaires de Technologies; IUT) in 1966 and by the establishment in 1991 of vocational units (Instituts Universitaires Professionnalisés; IUP), which work closely with businesses. Students may also apply to a number of prestigious *grandes écoles*, which are even more highly regarded than the universities, especially in the engineering and technical fields. The best-known among these is the École Polytechnique ("Polytechnic School"); founded in 1794 to recruit and train technicians for the army, it has become the most important technical school in both the public and private sectors.

Other features. Private education is mostly Roman Catholic. Although the French constitution proclaims that the state is secular, a 1959 law allows private establishments to sign government contracts that procure financial support in exchange for some control. Despite attempts made by the Socialist government of the early 1980s to bring private schools closer to the public sector, the system has remained basically unchanged.

Teachers are highly unionized and belong largely to the Federation for National Education and the National Syndicate of Instructors, as well as other left-wing unions. The main student unions are the National Union of French Students (Union National des Étudiants de France; UNEF), the quasi-communist UNEF Renouveau, the Union of Communist Students of France, and the National Confederation of French Students.

(F.B./J.F.P.B./J.N.T./Ed.)

Cultural life

For much of its history, France has played a central role in European culture. With the advent of colonialism and global trade, France reached a worldwide market, and French artistic, culinary, and sartorial styles influenced the high and popular cultures of countries around the globe. Today French customs, styles, and theories remain an influential export, as well as a point of great national pride, even as French intellectuals worry that the rise of globalism has prompted, in the words of the historian Pierre Nora, "the rapid disappearance of our national memory."

CULTURAL MILIEU

French culture is derived from an ancient civilization composed of a complex mix of Celtic, Greco-Roman, and Germanic elements. Monuments, especially from the period of Roman occupation, are numerous and include the amphitheatre at Arles, the *arènes* ("arenas") in Paris, and the aqueduct at Pont du Gard.

Cultural development in the Middle Ages

During the Middle Ages a rich culture developed, fostered in particular by monks and scholars in monasteries and universities and encouraged well into the 18th century by a system of royal and aristocratic patronage. Important trade fairs in growing cities such as Paris, Nancy, Strasbourg, and Lyon enabled the spread of artistic ideas and cultural trends to and from other regions, placing France at the centre of a nascent European high culture that would reach its greatest expression in the Renaissance. From the early 1700s and with the development of a middle class, the bourgeoisie, culture became more generally accessible. This was the age of the Enlightenment, of inquiry and question. Cultural activity remained largely centred in Paris, but smaller cities such as Aix-les-Bains, Grenoble, and Lyon were vital in their own right. The culture of the Enlightenment was built on reason and analytic argumentation, mirrored, as political scientist Alexis de Tocqueville remarked, in the French Revolution's

> attraction for general theories, for general systems of legislation, the exact symmetry of laws . . . the same desire to remake the entire constitution at once following the rules of logic and in accordance with a single plan, instead of seeking ways to amend its parts.

Among its tenets was the idea of meritocracy, or an aristocracy of ability and intelligence, which accorded a central place to intellectuals unknown in most other societies and opened France's schools to students from the provinces without regard for social class.

With free primary education compulsory by the late 19th century, basic literacy ensured that the general cultural level was raised. This was further aided by the increase in the number of newspapers and, later, by the development of radio, cinema, television, and the Internet. After World War II the intellectual and social development of lower-income groups benefited from the decision to make free secondary education compulsory up to age 16. Cultural literacy expanded as newspaper circulations rose, lending libraries proliferated, and in 1954 a revolution began in paperback books (*livre de poche*). This last development met with enormous success, providing people of all ages and classes with much greater access to literature and other forms of specialized knowledge.

The Ministry of Culture and Communications oversees the major cultural institutions of the nation. The department, first led by novelist André Malraux, seeks to redouble arts awareness among ordinary people, support the creation of new art, and protect existing French forms and properties as wide-ranging as monuments and language. The cultural map of France remains firmly centred on Paris, despite increased expenditure by local authorities on cultural activities following the decentralization legislation of the early 1980s. Yet, while serving, often self-consciously, the interests of the whole nation, the capital is aware of its own internal differences. Most of the city's *arrondissements* (municipal districts) have groups actively researching their history and traditions, and local art exhibitions and concerts are encouraged. In the rest of the country, provincial culture is strong and often fiercely defended—for example, in Brittany, parts of the south, and Alsace.

French culture has felt the impact made by immigrants, especially those from North Africa beginning in the 1960s. The Muslim communities that have formed, notably in Paris and Marseille, have not escaped discrimination, but there is a widespread acknowledgment of their contributions to cuisine, music, dance, painting, and literature. Verlan, a slang of standard French that reverses and reshuffles French syllables and spellings, traces its roots to the 19th century but was revived by postwar immigrant communities and in recent decades has made inroads into mainstream society. Beginning in the 1980s, second- and third-generation North Africans were often referred to as *les beurs*, and *beur* cinema, *beur* comics, and *beur* radio, among other forms of expression, have found a large audience. The label *beur* is itself a Verlan term for *arabe*, the French word for Arab. In addition, Asian and sub-Saharan African immigrants have attained prominence as artists, writers, and musicians in France's increasingly multicultural society.

DAILY LIFE AND SOCIAL CUSTOMS

In comparison with the immediate postwar era, the French now devote far more time to leisure and cultural pursuits, largely as a result of a shorter workweek, more years spent in education, and greater affluence. The increasing emphasis on home entertainment provided by television, stereo, and personal computers has not reduced cinema or theatre attendance; on the contrary, the number of moviegoers grew significantly in the 1990s.

The popularity of cultural activities is also evident, with increasing visits to historic monuments, art galleries, and museums. Especially attractive are interactive exhibitions at museums, such as the Cité de Sciences et de l'Industrie (City of Science and of Industry) at Le Parc de la Villette in Paris or the Futuroscope theme park near Poitiers. Interest also has been revived in local and regional cultures, often as part of new initiatives to develop tourism, and annual national festivals, such as the Fête de la Musique, are extremely successful.

French cuisine

Although French cuisine has a reputation as a grand national feature, regional differences are marked. Some local dishes have achieved international fame, even if they are often poorly imitated. Among these are the seafood soup, *bouillabaisse*, from Marseille; *andouillette*, a form of sausage from Lyon; *choucroute*, pickled cabbage from Alsace; and *magret de canard*, slices of breast of duck from Bordeaux. France is also renowned for the range and quality of its cheeses. More than 300 varieties are recognized. The majority are produced from cow's milk, including Camembert (Normandy), Brie (Île-de-France), Comté (Franche-Comté), Saint-Nectaire (Auvergne), and Reblochon (Savoy). Cheese is also made from ewe's milk, as in the case of Roquefort (Aveyron), as well as from goat's milk. Perhaps the best-known exports of France are the wines from some of the world's great vineyards in Burgundy, Bordeaux, and the Rhône valley. However, the reputation of French cuisine has not prevented the proliferation of fast-food outlets in France, especially over the past few decades. French consumption of wine and tobacco has dropped steadily since the mid-20th century, a mark of the nation's increased attention to health.

Paris is internationally known for its haute couture, exemplified by such houses of high fashion as Coco Chanel, Christian Dior, Hubert de Givenchy, Yves Saint Laurent, Jean-Paul Gaultier, and Christian Lacroix. Traditional dress is occasionally seen in many regions, although it is largely reserved for official ceremonies and festivals. Regional differences often reflect local customs of dressmaking and embroidery, the availability of fabrics, and adaptations to local climatic conditions. Headdresses vary greatly, ranging from elaborate lace wimples found in Normandy and Brittany to the more sober beret of southwestern France or the straw hat, worn typically in and around the area of Nice.

Jets trailing the French national colours over the Champs-Élysées in Paris, during the annual Bastille Day parade.

In addition to the Roman Catholic holy days, the French celebrate Bastille Day on June 14, commemorating the rise of the French Republic via the fall of the prison fortress of the Bastille in Paris in 1789 at the start of the French Revolution. "La Marseillaise," the French national anthem and one of the world's most recognizable national anthems, also memorializes the Revolution.

THE ARTS

Literature. French literature has a long and rich history. Traditionally it is held to have begun in 842 with the Oath of Strasbourg, a political pact between Louis the German and Charles the Bald, the text of which survives in Old French. The Middle Ages are noted in particular for epic poems such as *La Chanson de Roland* (*c.* 1100; *The Song of Roland*), the Arthurian romances of Chrétien de Troyes, and lyric poetry expressing romantic love. In the 16th century the Renaissance flourished, and figures such as the poet Pierre de Ronsard, the satirist and humorist François Rabelais, and the quintessential essayist Michel de Montaigne, were to become internationally acknowledged. French Neoclassical drama reached its apotheosis during the next hundred years in the tragedies of Pierre Corneille and Jean Racine. During the same period, Molière displayed his vast and varied talents in the theatre, particularly as a writer of comedies; Jean de La Fontaine produced moralistic verse in his *Fables*; and Madame de La Fayette created the classic *La Princesse de Clèves* (1678), generally considered the first French psychological novel.

Voltaire, Denis Diderot, and Jean-Jacques Rousseau dominated the 18th century, especially with their philosophical writings, though they made major contributions to all genres, and Voltaire's novel *Candide* (1759) is notable for its literary quality and distillation of Enlightenment ideals. Other authors of the period include playwright Pierre-Augustin Caron de Beaumarchais, best known for works such as *Le Mariage de Figaro* (1784; *The Marriage of Figaro*), and Pierre Choderlos de Laclos, remembered for his epistolary novel *Les Liaisons dangereuses* (1782; *Dangerous Acquaintances*). The 19th century witnessed the emergence of a series of writers who substantially influenced the development of literature worldwide, including the novelists Honoré de Balzac, Stendhal, Gustave Flaubert, and Émile Zola along with the poets Charles Baudelaire, Stéphane Mallarmé, and Arthur Rimbaud. Added to these was the Romantic writer Victor Hugo, whose creative energy expressed itself in all literary forms, as well as in painting.

The "new novel"

French literature in the 20th century both carried on the earlier traditions and transformed them. While the complexity of French poetry continued in the work of Paul Valéry, Guillaume Apollinaire, Paul Claudel (also a major dramatist), Saint-John Perse, Paul Éluard, Louis Aragon, René Char, and Yves Bonnefoy, the art of the novel was given new direction by Marcel Proust, in *À la recherche du temps perdu* (1913–27; *Remembrance of Things Past*). The first half of the century also produced such notable writers as André Gide, François Mauriac, André Malraux, Albert Camus, and Jean-Paul Sartre, the last arguably the chief exponent of existentialist philosophy. Their work was followed in the 1950s by the *nouveau roman* ("new novel") and by the emergence of writers such as Alain Robbe-Grillet, Nathalie Sarraute, Michel Butor, Claude Mauriac, Marguerite Duras, and Claude Simon, whose works have entered the canon of literature. Since the 1970s Michel Tournier, Patrick Modiano, Erik Orsenna, and Georges Perec have become leading novelists; feminist writers, including Hélène Cixous, Annie Leclerc, Jeanne Champion, and Marie Cardinal, have also made significant contributions. French authors have won a number of Nobel Prizes for Literature.

The literature of the 20th century was notable for its openness to nonnative writers: the Irish writer Samuel Beckett, for instance, the Czech expatriate Milan Kundera, the Russian emigrant Andreï Makine, and Chinese exile Gao Xingjian have all produced major works in French. Georges Simenon and Marguerite Yourcenar, both born in Belgium in 1903, were considered French writers, though they often lived outside France.

The works of French playwrights have enjoyed international acclaim for centuries, from the 17th-century comic theatre of Molière to the 19th-century cabaret productions known as Grand Guignol. In theatre in the 20th and 21st centuries three important currents can be discerned. Traditional playwriting was carried on largely by Jean Anouilh, Claudel, Jean Giraudoux, Henry de Montherlant, and Camus, but experimentation with both form and content also developed. Before World War II, Jean Cocteau in particular made his mark (as did to a lesser degree Claudel), but innovation came with Fernando Arrabal, Arthur Adamov, Beckett, Jean Genet, and the Romanian exile Eugène Ionesco. Since the 1950s producers have also made an important contribution to theatre; Roger Planchon, Jean-Louis Barrault, Peter Brook, Marcel Maréchal, and Ariane Mnouchkine in particular have shared in both creating new works and revitalizing traditional ones.

Philosophy and criticism have always played a central part in French intellectual and cultural life. The Surrealist movement, led by André Breton, among others, flourished in the 1920s and '30s. Existentialism in both Christian and atheist forms was a powerful force in the mid-20th century and was championed by Sartre, Étienne Gilson, Gabriel Marcel, and Camus (though he rejected the label). More broadly, Roman Catholicism and Marxism in orthodox or revised forms have influenced a large number of creative writers, including the Roman Catholic Georges Bernanos and Sartre, who was a Marxist of a sort. Since the 1950s new criticism, which began with structuralism—itself largely inspired by the anthropological work of Claude Lévi-Strauss in *Mythologiques*, 4 vol. (1964–71), and *Tristes Tropiques* (1955)—has challenged the monopoly of the historical approach to works of art and especially literature. Not limited to literary criticism, structuralism was an important component of philosophy among proponents such as Louis Althusser. The most popular expression of this approach was perhaps the work of Roland Barthes, including *Mythologies* (1957), but his work fragmented into various branches—linguistic, genetic, psychobiographical, sociocultural—each with its exponents and disciples increasingly embroiled in academic, and often abstruse, debate. Following on the heels of structuralism, poststructuralism was associated with such figures as Jacques Derrida, Michel Foucault, Jacques Lacan, Julia Kristeva, Giles Deleuze, Hélène Cixous, Luce Irigaray, and Jean-François Lyotard. Other philosophers of recent note include André Glucksmann, Bernard Henri-Lévy, and Michel Serres.

The fine arts. French traditions in the fine arts are deep and rich, and painting, sculpture, music, dance, architecture, photography, and film all flourish under state support.

Painting and sculpture. In painting there was a long tradition from the Middle Ages and Renaissance that, while perhaps not matching those of Italy or the Low Countries, produced a number of religious subjccts and court portraits. By the 17th century, paintings of peasants by Louis Le Nain, of allegories and Classical myths by Nicolas Poussin, and of formally pastoral scenes by Claude Lorrain bcgan to givc Frcnch art its own charactcristics.

Within the next hundred years, styles bccamc evcn more wide-ranging: mildly erotic works by François Boucher and Jcan-Honoré Fragonard; cnigmatic sccnes such as *Pierrot*, or *Gilles* (*c.* 1718–19), by Antoinc Wattcau; interiors by Jean-Siméon Chardin that were oftcn tingcd with violence, as in *La Raie* (*c.* 1725–26; "The Ray"); emotive portraits by Jean-Baptiste Greuze; and rigorous Ncoclassical works by Jacques-Louis David.

Much as the Académie Françaisc rcgulatcd literature, painting up to this time was subjcct to rulcs and convcntions established by the Academy of Fine Arts. In thc 19th century some artists, notably J.-A.-D. Ingrcs, followcd these rulcs. Others reacted against academic conventions, making Paris, as the century progrcsscd, a ccntre of the Western avant-garde. Beginning in the 1820s, the bold croticism and "Orientalism" of the works of Romantic painter Eugène Delacroix angcrcd the academy, while at midcentury the gritty Realism of thc art of Gustavc Courbet and Honoré Daumier was viewed as scandalous.

The Imprcssionists

Perhaps the greatest brcak from academic conventions came about through the Impressionists, who, inspircd in part by the daring work of Édouard Manet, brought on a revolution in painting beginning in the late 1860s. Some artists from this movement whose work became internationally celebrated include Claude Monet, Camille Pissarro, Alfred Sisley, and Edgar Degas. Important Post-Impressionists include Paul Cézanne, Henri de Toulousc-Lautrec, Paul Gauguin, Pierre-Auguste Renoir, and Georges Seurat.

French sculpture progressed from the straight-lined Romanesque style through various periods to reach its height in the work of Auguste Rodin, who was a contemporary of the Impressionists and whose sculpture reflected Impressionist principles. Another from this time, Aristide Maillol, produced figures in a more Classical style.

Pablo Picasso, one of the most influential forces in 20th-century art, was born in Spain but spent most of his artistic life in France. His oeuvre encompasses several genres, including sculpture, but he is best known for the Cubist paintings he created together with French artist Georges Braque at the beginning of the century. One of Picasso's greatest rivals was French painter Henri Matisse, whose lyrical work, like Picasso's, spanned the first half of the century. In the period between the World Wars, Paris remained a major centre of avant-garde activity, and branches of prominent international movements such as Dada and Surrealism were active there.

By mid-century, however, Paris's dominance waned, and the focus of contemporary art shifted to New York City. Prominent artists working in France have included Jean Dubuffet, Yves Klein, Swiss-born Jean Tinguely, Hungarian-born Victor Vasarely, Niki de Saint-Phalle, Bulgarian-born Christo, Daniel Buren, and César.

Major art exhibits are held regularly, mainly in Paris, and training for aspiring artists is provided not only at the prestigious École des Beaux-Arts ("School of Fine Arts") in Paris but also at a number of provincial colleges. Courses for art historians and restorators are available at the School of the Louvre. Building on their country's rich history as a leader in furniture design and cabinetry, French craftsmen of all sorts today study at the National Advanced School of Decorative Arts and other institutions.

Music. The growth of classical music parallels that of painting. Despite work from earlier periods by Louis Couperin, Jean-Philippe Rameau, and Jean-Baptiste Lully, for example, French music gained a broad international following only in the 19th and early 20th centuries. Such composers as Hector Berlioz, Camille Saint-Saëns, Maurice Ravel, Claude Debussy, and the Polish-born Frédéric Chopin created a distinctively French style, further developed in the 20th century by composers such as Pierre Boulez, Darius Milhaud, and Erik Satie. In the late 20th century much experimentation occurred with electronic music and acoustics. The Institute for Experimentation and Research in Music and Acoustics (Institut de Recherche et Coordination Acoustique/Musique), in Paris, remains devoted to musical innovation. A new generation of French musicians includes the pianists Hélène Mercier and Brigitte Engerer.

Training for the musical profession remains traditional. Local conservatoires throughout the country provide basic grounding; some provincial schools—at Lyon and Strasbourg, for example—offer more advanced work, but young people with talent aim for the National Conservatory of Music in Paris, where Nadia Boulanger taught. Since World War II, Paris has hosted internationally famous conductors, such as Herbert von Karajan and Daniel Barenboim, who have made contributions in revitalizing an interest in classical music. Major visiting orchestras perform at the Châtelet Theatre or the Pleyel Concert Hall, and concerts are given by smaller groups in many of the churches. There is a network of provincial orchestras.

Although interest in classical music has grown at the amateur level, it is practiced by a relatively small number. The young tend to be preoccupied with popular music, especially that imported from the United States and the United Kingdom. The tradition of the French chanson, the romantic French ballad, has continued, however, following such legendary stylists as Juliette Gréco, Edith Piaf, Belgian-born Jacques Brel, Charles Aznavour, and Georges Brassens. Moreover, France has produced rock performers such as Johnny Hallyday and the group Téléphone, as well as chanteuses of the 1960s such as Françoise Hardy, known for pop music called *yé-yé* ("yeah-yeah"). Other well-known artists of recent years include Julien Clerc, Jean-Jacques Goldman, and Renaud. However, all have been considerably more popular nationally than internationally.

The French chanson

The Paris Opéra, established in 1669, prospered under the efforts of Lully, Rameau, Christoph Gluck, Berlioz, Georges Bizet, and Francis Poulenc. France was known for the traditions of opéra comique and grand opera, among others.

Dance. France is famous for developing ballet. In 1581 the *Ballet comique de la reine* was performed at the French court of Catherine de Médicis. Because it fused the elements of music, dance, plot, and design into a dramatic whole, it is considered the first ballet. The *Ballet comique* influenced the development of the 17th-century *ballet de cour* (court ballet), an extravagant form of court entertainment.

In 1661 Louis XIV established the Académie Royale de Danse (now the Paris Opéra Ballet); the company dominated European theatrical dance of the 18th and early 19th centuries. Pierre Beauchamp, the company's first director, codified the five basic ballet positions. Extending the range of dance steps were virtuosos such as Gaëtan Vestris and his son Auguste Vestris and also Marie Camargo, whose rival Marie Sallé was known for her expressive style.

In his revolutionary treatise, *Lettres sur la danse et sur les ballets* (1760), Jean-Georges Noverre brought about major reforms in ballet production, stressing the importance of dramatic motivation, which he called *ballet d'action*, and decrying overemphasis on technical virtuosity. In 1832 the Paris Opéra Ballet initiated the era of Romantic ballet by presenting Italian Filippo Taglioni's *La Sylphide*. Jean Coralli was the Opéra's ballet master at the time, and the company's dancers of this period included Jules Perrot and Arthur Saint-Léon.

In the 20th century ballet was rejuvenated under the leadership of Russian impresario Sergey Diaghilev, who founded the avant-garde Ballets Russes in Paris in 1909. For the next two decades it was the leading ballet company in the West. The original company was choreographed by Michel Fokine. Elsewhere in Paris, Serge Lifar, the Russian-born ballet master of the Paris Opéra, reestablished its reputation as a premier ballet troupe.

Dance entertainments of a lighter kind also were developed in France. In 19th-century Paris the all-female cancan became the rage. After 1844 it became a feature of music halls, revues, and operetta.

Architecture. With a rich and varied architectural heritage (which helped to spawn, among other styles, Gothic, Beaux Arts, and Art Deco) and an organized and competitive program of study, France has shown itself to be open to a variety of styles and innovations. For example, Le Corbusier, much of whose work can be found in France, was Swiss. The development of architecture has also been sustained by the central government's penchant for *grands projets*, or great projects. The country, however, has not produced as many designers of international repute in recent years as have other Western nations. Major achievements such as the Pompidou Centre, the pyramid entrance to the Louvre, and the Grand Arch have resulted from plans submitted in open competition by foreign architects. Recent architects of acclaim, of French origin or working in France, have included Jean Nouvel, Dominique Perrault, Adrien Fainsilber, Paul Andreu, Swiss-born Bernard Tschumi, and Catalonian Ricardo Boffil of Spain. Among important contemporary designers are Andrée Putman and Philippe Starck.

Photography. Jacques Daguerre, one of the recognized founders of modern photography in the early 19th century, began the evolution of an art form that has flourished in France. In the 20th century the work of such photographers as Eugène Atget, Henri Cartier-Bresson, and Robert Doisneau ensured that the art had a dimension beyond journalistic and commercial purposes, which was apparent in the installation art of later figures such as Christian Boltanski. In 1969 an annual festival was established at Arles, and in 1976 a national museum was created. The French popularization of photography through posters and postcards was one of the most remarkable cultural events of the late 20th century.

The cinema. French cinema has occupied an important place in national culture for more than 100 years. August and Louis Lumière invented a motion-picture technology in the late 19th century, and Alice Guy-Blaché and others were industry pioneers. In the 1920s French film became famous for its poetic realist mode, exemplified by the grand historical epics of Abel Gance and the work in the 1930s and '40s of Marcel Pagnol and others. A generation later the *nouvelle vague*, or New Wave, produced directors such as Jean-Luc Godard and François Truffaut, who "wrote" with the camera as if, in critic André Bazin's words, it were a *caméra-stylo* ("camera-pen"). This shift was accompanied by an "intellectualization" of the cinema reflected in the influential review *Cahiers du cinéma*, in the establishment of several schools in Paris and the provinces where film could be studied, and in the founding of film museums such as the Cinémathèque ("Film Library") in Paris.

Other directors of international stature include Jean Renoir, Jacques Tati, Jean-Pierre Melville, Alain Resnais, Eric Rohmer, Robert Bresson, and Louis Malle. They exemplified the auteur theory that a director could so control a film that his or her direction approximated authorship. Filmmakers such as Agnès Varda, Claude Chabrol, Jacques Demy, Bertrand Tavernier, and Claude Bérri, as well as Polish-born Krzystof Kieslowski, extended these traditions to the end of the century.

The leading film stars of the 20th century ranged from Fernandel, Maurice Chevalier, and Arletty to Brigitte Bardot, Gérard Depardieu, and Catherine Deneuve. One of the world's premier film festivals is held annually at Cannes, where the Palme d'Or is awarded to the best motion picture—most, in recent years, have come from outside France, a source of consternation to French film devotees. As in television, the French film industry faces competition from the United States and the United Kingdom. This led the government in the early 1990s to elicit the support of the European Commission to protect its native film industry.

CULTURAL INSTITUTIONS

Administrative bodies. Despite increasing support from the private sector, various ministries, such as those of National Education and of Culture and Communications, are ultimately responsible for the promotion of cultural activities. Local authorities, particularly those representing the major towns and cities, as well as a variety of associations also fund cultural activities. The importance attached to culture is reflected in the substantial increase in expenditure and personnel working in this field and the growth of related industries (music, publishing, broadcasting technologies). About one-third of the populace belong to some form of cultural association. Abroad, French culture is promoted through the work of counselors and attachés at embassies, visiting speakers, the Alliance Française, and the French lycées in major cities. French institutes provide lectures, language courses, and access to books and newspapers. There are also associations ensuring international links, such as the United Nations Educational, Scientific and Cultural Organization and the International Association of French Teachers, both headquartered in Paris.

French culture abroad

Museums and monuments. Support and encouragement for cultural activities of all kinds are provided by a large number of museums, centres, and galleries, many of which are ultimately the responsibility of government ministries. In the provinces many museums traditionally reflecting their region's activities have been expanded and renovated and, like those at Saint-Étienne and Strasbourg, have achieved national importance. It is in Paris, however, that the nation's principal museums are to be found. The Louvre Museum, containing one of the world's great art collections, was extensively remodeled at the end of the 20th century, with a notable addition of a dramatic steel-and-glass pyramid entrance. The Musée d'Orsay, created out of a former railway station, houses a fine, large collection of 19th- and early 20th-century art and artifacts, while the Georges Pompidou National Centre of Art and Culture, with its industrially inspired architecture, concentrates on the 20th century. The centre has an important library and media collection, and the square in front of it provides an open-air stage for jugglers, musicians, fire-eaters, and other street performers. Smaller museums, often containing substantial private collections, are numerous; three of particular interest are the Marmottan, Cognacq-Jay, and Orangerie. In addition to the larger museums, the Grand Palais and the Petit Palais regularly provide the setting for important exhibitions, and many of the national institutes offer French people the opportunity to appreciate works from different cultures. Particularly important in this respect are the Museum of the Arab World and the Museum of African and Oceanic Arts.

Since the 1950s there has been a national program for the conservation and renovation of important historic areas. The medieval *vieux quartiers* of Lyon have been tastefully restored, as has the 18th-century Place du Parlement in Bordeaux, for example. Many significant buildings have been saved by private funding, and government financial assistance is also available, usually on the condition that the property is opened to the public. In Paris the houses in the Marais district and on the Île Saint-Louis have had their original splendour restored, while around Montparnasse, for example, poor areas of 19th-century building have been bulldozed to make room for fashionable modern apartment blocks. Four structures in particular mark the later years of the 20th century: the entrance to the Louvre; the Bastille Opera; the Grand Arch in La Défense, a futuristic business district west of Paris; and the national library, Bibliothèque François Mitterrand, all of which received the strong support of Mitterrand as monuments to his presidency.

Significant structures of the late 20th century

SPORTS AND RECREATION

Although the French have recently developed a taste for a new range of sporting activities, such as mountain biking, cross-country skiing, and rock climbing, the most common forms of recreation in France seem to be nonphysical or relatively sedentary—talking, reading, eating, going to the cinema, and so on. This no doubt has something to do with the relative absence of programmed physical education at school. Certainly organized sport has a place in French society, however, with cycling, swimming, football (soccer), skiing, tennis, *boules* (*pétanque*), and, increasingly, golf, basketball, and martial arts being the most popular activities. Walking and jogging, too, are important, and a national network of paths (*grandes randonnées*) is well maintained. Popular seaside vacation resorts include Saint-Tropez, Cannes, and Cap d'Agde on the Mediterranean, the Île de Ré and La Baule-Escoublac on the Atlantic coast, and Le Touquet on the English Channel. Inland the French Alps, the Massif Central, and the national and regional parks, such as the Morvan regional nature park in Burgundy, attract campers and hikers. Newer, artificially created attractions include a growing number of theme parks, ranging from Disneyland at Paris to more specialized sites such as the Nausicaä sea-world museum at Boulogne-sur-Mer.

The nation's showcase sporting event is the Tour de France, an international cycling road race that attracts hundreds of thousands of spectators each year. Established more than a century ago, the annual summer race covers some 3,600 kilometres (2,235 miles) over the course of three weeks, finishing in Paris. Football, especially in the larger towns, is extremely popular. The 1998 World Cup was both hosted and won by France. More than five million French people ski, and many children have the opportunity to go on school skiing trips in February; the principal resorts are in the northern Alps, notably in Savoy (Savoie). French bowls, or *boules*, is played by thousands and is highly organized at both national and local levels. Handball has an avid following, and rugby is mostly played in the southwest. Educator Pierre, baron de Coubertin, revived the Olympic Games in modern form in 1896 and founded the International Olympic Committee. Games in Paris soon followed in 1900 and 1924. Chamonix was the site of the inaugural Winter Olympic Games in 1924, followed by Grenoble in 1960 and Albertville in 1992. Olympic highlights include the successes of skier Jean-Claude Killy in 1968, the national football team in 1984, and runner Marie-José Pérec in the 1990s.

MEDIA AND PUBLISHING

Television and radio. In 1989 the Socialist government formed the Supreme Audiovisual Council (Conseil Supérieur de l'Audiovisuel; CSA) to supervise radio and television broadcasting. There are both public and private stations. Programs also have been broadcast and received via satellite since 1984, and cable broadcasting began in 1987. More than three-fourths of the population watch television an average of 22 hours per week.

Although it has been largely eclipsed by television and video, radio still has cultural impact. Two agencies managed by Radio France—France Culture and France Musique—provide the bulk of the cultural programs, but they are often indifferently presented. Major stations such as France-Inter (public) or Europe No. 1 (private) have resorted increasingly to a mix of popular music, news items, quizzes, and talk shows. Smaller private stations cater to specialized interests—for example, Radio Notre Dame (religion) and Radio Classique (classical music). Popular music stations such as Fun Radio and Skyrock have grown rapidly. Since 1994, however, with the aim of protecting French culture, such stations have been obliged to dedicate 40 percent of their playlists to songs in French.

The press. The newspaper has a long history and a strong tradition in France. The French press, in the form of reviews and news sheets, has its origins in the early 17th century with Théophraste Renaudot's *La Gazette*, which began in 1631. It was not for another 250 years, however, with the passage of an act in 1881 allowing greater freedoms, that the press began to expand significantly. At the beginning of World War II, Paris offered some 30 daily papers, many with national followings and most with a clear political affiliation. The number of newspapers (and periodicals as well) declined sharply after the war, in some cases for political reasons but in others as a result of takeovers, collaborative ventures, and competition from television. In 1944 the Paris-based *Le Monde* was founded, and it became the most informed and influential of modern French newspapers. Other influential and widely circulating Paris dailies include *Le Figaro*, *Libération*, and *France-Soir*. Among the smaller dailies are the Roman Catholic *La Croix l'Événement* and the communist *L'Humanité*. In the 1950s illustrated magazines began to proliferate (echoing a trend of the 1930s); some of these were popular magazines of general interest and some were directed at specific markets, such as *Elle*, *Marie-Claire*, and *Vogue Paris* for women and *L'Express*, *Le Point*, and *Le Nouvel Observateur*, which are political. Few, however, have enjoyed the popular success and wide distribution of the news-oriented *Paris-Match*. By the late 20th century, three specific factors characterized the French press: first, the expansion of the regional daily paper, with *Ouest-France* enjoying the largest circulation in the country; second, the growth of specialized magazine journalism; and third, the appearance since the early 1960s of free newspapers essentially for advertising purposes, which are distributed weekly in the millions.

HISTORY

Gaul

Geographic-historical scope. Gaul, in this context, signifies only what the Romans, from their perspective, termed Transalpine Gaul (Gallia Transalpina), or "Gaul across the Alps." Broadly, it comprised all lands from the Pyrenees and the Mediterranean coast of modern France to the English Channel and from the Atlantic to the Rhine and the western Alps. The Romans knew a second Gaul, Cisalpine Gaul (Gallia Cisalpina), or "Gaul this side of the Alps," in northern Italy—which, however, does not belong to the history of France. Transalpine Gaul came into existence as a distinct historical entity in the middle of the 1st century BC, through the campaigns of Julius Caesar (lived *c.* 100–44 BC), and disappeared late in the 5th century AD. Caesar's heir, the emperor Augustus (reigned 27 BC–AD 14), divided the country into four administrative provinces: Narbonensis, Lugdunensis, Aquitania, and Belgica. Following recognition of the impossibility of large-scale expansion beyond the Rhine, rulers of the Flavian dynasty (69–96) annexed the region between the middle Rhine and upper Danube, roughly the Black Forest region, to secure communications between Roman garrisons by then permanently established on both rivers. This area was called the Agri Decumates—Ten Cantons (the precise significance of the name being unknown). Its eastern border, conventionally referred to as the limes, assumed its final shape, as a defended palisade and ditch, under Antoninus Pius (138–161). The Agri Decumates were attached to Upper Germany (Germania Superior), one of two new frontier provinces (the other being Lower Germany [Germania Inferior]) created by the last Flavian emperor, Domitian (81–96). For greater administrative efficiency, the emperor Diocletian (284–305) subdivided all six Gallic provinces, forming a total of 13.

Agri Decumates

The people. Gaul was predominantly a Celtic land (see below), but it also contained pre-Celtic Ligurians and Iberians in the south and southwest and more recent Germanic immigrants in the northeast. Neighbouring Celtic communities on the Danube and in northern Italy, however, were not included. The south, in addition, had been heavily influenced by the Greek colony of Massilia (Marseille, founded around 600 BC) and its daughter-cities. In brief, the Gaul that was the foundation of medieval France was not a "natural" unit but a Roman construct, the result of a decision to defend Italy from across the Alps.

THE ROMAN CONQUEST

In the 2nd century BC Rome intervened on the side of Massilia in its struggle against the tribes of the hinterland, its main aim being the protection of the route from Italy to its new possessions in Spain. The result was the formation, in 121 BC, of "The Province" (Provincia, whence Provence), an area spanning from the Mediterranean to Lake Geneva, with its capital at Narbo (Narbonne). From 58 to 50 BC Caesar seized the remainder of Gaul. Although motivated by personal ambition, Caesar could justify his conquest by appealing to deep-seated Roman fear of Celtic war bands (see below) and further Germanic incursions (late in the 2nd century BC the Cimbri and Teutoni had invaded The Province and threatened Italy). Because of chronic internal rivalries, Gallic resistance was easily broken, though Vercingetorix' Great Rebellion of 52 had notable successes before it expired in the cruel siege of Alesia (Alise-Sainte-Reine).

Caesar's conquest of Gaul

Gaul under the High Empire (*c.* 50 BC–*c.* AD 250). The first centuries of Roman rule were remarkable for the speedy assimilation of Gaul into the Greco-Roman world. This was a consequence of both the light hand of the Roman imperial administration and the highly receptive nature of Gallic-Celtic society. Celtic culture had originated on the upper Danube around 1200 BC. Its expansion westward and southward, through diffusion and migration, was stimulated by a shift from bronze- to ironworking. Archaeologically, the type of developing Celtic Iron Age culture conventionally classified as Hallstatt appeared in Gaul from about 700 BC; in its La Tène form it made itself felt in Gaul after about 500 BC. Initially the Romans, who had not forgotten the capture of their city by Brennus, the leader of Celtic war bands, about 390 BC, despised and feared the Celts as barbarian savages. Until the end of the 1st century BC, they disparaged Gaul beyond The Province as Gallia Comata ("Long-Haired Gaul"), mocked and exploited the Gauls' craving for wine, and generally mismanaged The Province itself.

Gaul by then, however, was not far behind Rome in its evolution. In the south, Ligurian communities had long emulated the Hellenic culture of Massilia, as may be seen in the settlement of Entremont (near Aquae Sextiae [Aix-en-Provence]). In the Celtic core, Caesar found large nations (his *civitates*) coalescing out of smaller tribes (*pagi*) and establishing urban centres (*oppida—e.g.*, Bibracte [Mont Beuvray], near Augustodunum [Autun]), which, though quite unlike the classical city-states, were assuming significant economic and administrative functions. After the corrupt Roman Republic was replaced by the empire and its more prudent rule, these advances in Transalpine Gaul could be exploited for the imperial good. The Province, now Narbonensis, was planted with settlements of retired Roman soldiers (*coloniae*, "colonies"—

e.g., Arelate [Arles]); it soon became a land of city-states and was comparable with Italy in its way of life. In the remaining "Three Gauls," such colonies were few; there the *civitates* were retained, as was the habit of fierce rivalry between their leaders. Competition, however, was diverted from war: status was now measured in terms of the level of Romanization attained by both the individual and his community.

Civitas-capitals

Northern Gaul therefore became a Romanized land too. This is dramatically reflected in the dominance of Latin as the language of education and government; French was to be a Romance tongue. Archaeologically, however, Romanization in Gaul is most evident in the emergence of the Greco-Roman city. Although the *civitates* were too large to act as true city-states, they contained towns, either already in existence (*e.g.*, Lutetia Parisiorum [Paris]) or newly founded (*e.g.*, Augustodunum, "Augustusville"), that could be designated as their administrative centres and developed, by local magnates at their own expense, in accordance with classical criteria. Thus, these *civitas*-capitals, as scholars term them, were characterized by checkerboard street grids and imposing administrative and recreational buildings such as forums, baths, and amphitheatres. Although they display vernacular architectural traits, they essentially follow the best Mediterranean fashion. Most were unwalled—an indicator of the Pax Romana.

The mark of Rome is also discernible in the countryside, in the shape of villas. Villas of this period were, however, working farms as much as Romanized country residences—manor houses, not palaces. The survivors of the great Gallic aristocracy of the pre-Roman period, who first adopted Roman ways and who might eventually have constructed rural palaces, persisted into the 1st century AD but then seem to have been eclipsed by lesser landowners.

Scholars dispute the extent to which the mass of the Gallic population (at about 10 million, or 15 persons per square kilometre [39 persons per square mile], large for a preindustrial economy), free or slave, benefited from the new conditions, but there is no doubt that the landowners prospered. One of the great engines of their wealth was the Rhine army, which stimulated trade by purchasing its supplies from the interior. Commerce was greatly facilitated by a road network and system of river transport that had been expanded and improved under Roman administration. It is no accident that the capital of high imperial Gaul was Lugdunum (Lyon), the main Gallic road junction and a great inland port on the river route that led north to Colonia Agrippina (Cologne), the chief city of the two Germanies.

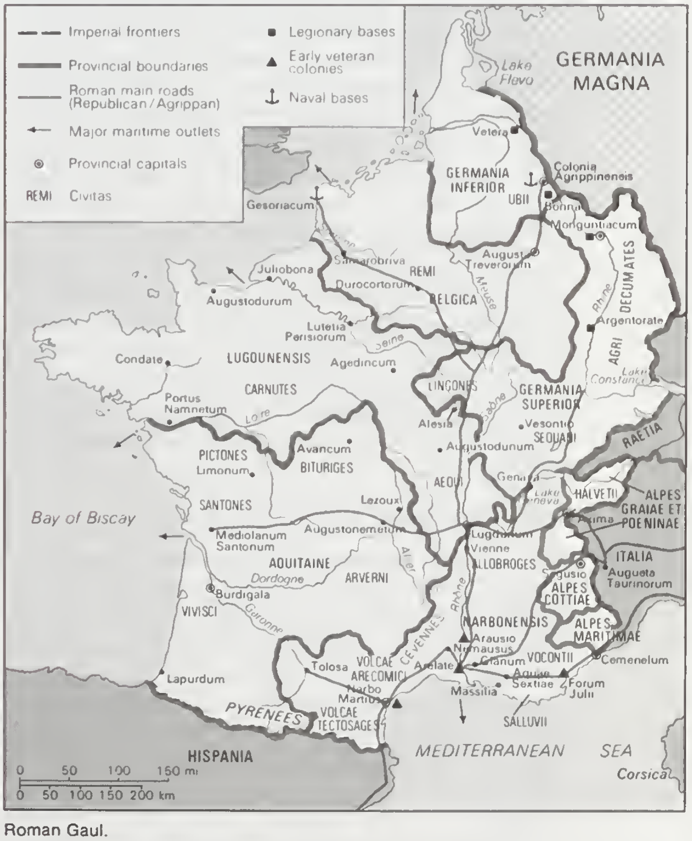
It is not surprising, therefore, that there was relatively little resistance to Roman rule; Vercingetorix was not an ancient Gallic hero. There were localized revolts in AD 21 and 69–70, but these were easily suppressed. They may have accelerated the demise of the old Gallic aristocracy; few Gauls subsequently pursued imperial Roman careers (for example, as senators). This diffidence, due initially perhaps to lingering Roman prejudice against Celts but reinforced by Gallic contentment with local responsibilities, may have served to keep Gallic wealth in Gaul.

Civil war and revolt

Gaul under the late Roman Empire (*c.* 250–*c.* 400). High Roman Gaul came to an end in an empirewide crisis characterized by foreign invasions and a rapid succession of rulers, as increased pressure on the empire's frontiers exacerbated its internal economic and political weaknesses. Priority was given to holding the Danube and the East; despite sporadic visits by emperors, the West was neglected. In 260 and 276 Gaul suffered depredation by two recent confederations of Germanic peoples, the Alemanni and the Franks (facing Upper and Lower Germany respectively). Civil war resulted in Gaul, Britain, and (for a while) Spain being governed by a line of "Gallic" emperors (beginning with Postumus [260–268]) before being reconquered by Aurelian in 274; there was further revolt in about 279–80. Although unity was reestablished and order of a sort restored by Aurelian (270–275), Probus (276–282), and Carinus (283–285), the country was much altered. For example, around 260 the Agri Decumates were abandoned, and, from about the reign of Probus, there began an extensive program of city fortification, though on very restricted circuits that cut through, and even used as building material, the proud structures of the previous age. The countryside was prey to marauding peasants. There was, however, no move to exploit the crisis to gain independence: the "Gallic Empire," though closely involving leading Gallic civilians, depended on the loyalty of the Rhine army; it thus championed Gallo-Roman, not Gallic, interests (essentially, the maintenance of a strong Rhine frontier).

After Diocletian and his successors radically reformed the empire in the late 3rd and early 4th centuries, Gaul enjoyed a new stability and even an enhanced role in imperial life. The reason for this was the empire's renewed commitment to defend Italy from the Rhine. To ensure the loyalty of the Rhine garrison and the civil population that depended on it for protection, imperial representation in the frontier region became permanent. An official of the highest rank, a praetorian prefect, was based there, and a series of emperors and usurpers (in particular, Constantine I [reigned 306–337], Julian [355–363], Valentinian I [364–375], Gratian [375–383], and Magnus Maximus [383–388]) resided there for at least part of their reigns. Their seat of government was usually Augusta Treverorum (Trier [German]; Trèves [French]), the former *civitas*-capital of the Treveri and capital of Belgica, now "the Rome of the West." (An interesting exception to the rule was Julian, who, with Trier rendered inhospitable by war, wintered in Paris, giving that city its first taste of future greatness.) Throughout the 4th century and especially in its latter half, the ever-present German menace as well as internecine strife occasionally caused the Rhine frontier to be broken, but it was always vigorously restored.

Some recovery of economic prosperity occurred, though it was fragile and uneven. The levying of taxes in kind rather than in cash may have weakened commerce, and the settlement of captive barbarians on the land indicates a rural labour shortage. Trier was endowed with magnificent buildings, but most Gallic cities never recovered their classical grandeur. The well-to-do, who were for the most part probably not descended from the aristocracy of high Roman Gaul (destroyed in the 3rd-century crisis), had



Roman Gaul.

Adapted from Westermann Grosser Atlas zur Weltgeschichte, Georg Westermann Verlag, Braunschweig loftier ambitions than their predecessors. Looking beyond the *civitates,* they eagerly sought posts in the imperial administration, now conveniently close to hand, basing their claim to advancement on their learning. (Gallo-Roman education, drawing vitality from the Gallo-Celtic love of eloquence, had long been renowned, but it blossomed fully in the 4th century in famous universities such as the one at Burdigala [Bordeaux].) As the century progressed, some educated Gauls grew extremely powerful; the best known, Ausonius (lived *c.* 310–*c.* 393), a poet and professor at Bordeaux, was appointed tutor of the future emperor Gratian and became his counselor. These worldly aristocrats, when not at court, favoured the country life; the later 4th century saw the rise of the palatial villa, especially in the southeast. Other Gauls looked to serve an even higher power; Christianity took root deeply in the land at this time. An episcopal hierarchy (based on the Roman provinces and *civitates*) was developed and monasticism was introduced by Martin of Tours (lived *c.* 316/336–397).

THE END OF GAUL (C. 400–C. 500)

From 395 the division of the Roman Empire between an eastern and a western half caused acute internal political stresses that encouraged barbarian penetration of the Danube region and even Italy. The Rhine frontier was again neglected, and the seat of the Gallic prefecture was moved to Arelate. The result was Germanic invasion and civil war. By 418, Franks and Burgundians were established west of the Rhine, and the Visigoths settled in Aquitania (Aquitaine). These Germans, however, were nominally allies of the empire, and, owing mainly to the energy of the Roman general Flavius Aetius, they were kept in check. The death of Aetius in 454 and the growing debility of a western imperial government hamstrung by the loss of Africa to the Vandals created a power vacuum in Gaul. It was filled by the Visigoths, at first indirectly through the nomination of the emperor Avitus (455–456) and then directly by their own kings, the most important being King Euric (466–484). The 460s and 470s saw steady Visigothic encroachment on Roman territory to the east; the Burgundians followed suit, expanding westward from Sapaudia (now Savoy). In 476 the last imperial possessions in Provence were formally ceded to the Visigoths.

Germanic invasions

Gaul suffered badly from these developments. Communities near the Rhine were destroyed by war. Refugees fled south, to Roman territory, only to find themselves burdened by crippling taxation and administrative corruption. As is evident from the works of the writer Sidonius Apollinaris (lived *c.* 430–*c.* 490), however, the economic power and with it the life-style of the Romano-Gallic aristocracy remained remarkably resilient, whether under Roman emperors or barbarian kings. Many aristocrats, as, for example, Sidonius himself, also confirmed their standing in their communities by becoming bishops. Until the middle of the 5th century, the leaders of Gallic society, lay and clerical, while learning to live with the barbarian newcomers, still looked to Rome for high office and protection. Thereafter they increasingly cooperated with the German rulers as generals and counselors. Thus, at least in the centre and south of the country, the Gallo-Roman cultural legacy was bequeathed intact to the successor-kingdoms. (J.F.Dr.)

Merovingian and Carolingian age

The period of the Merovingian and uninterrupted Carolingian Frankish dynasties (476–887) encompasses what scholars call the Early Middle Ages. After the 4th and 5th centuries, when Germanic peoples entered the Roman Empire in substantial numbers and brought the existence of that Mediterranean state to an end, the Franks played a key role in Gaul, unifying it under their rule. Merovingian and, later, Carolingian monarchs created a polity centred in an area between the Loire and Rhine but extending beyond the Rhine into large areas of Germany.

ORIGINS

Early Frankish period. In the second quarter of the 5th century, various groups of Franks moved southward toward the middle Rhine area (Cologne), the lower branches of the Moselle and Meuse, and the Atlantic coastal region. In the latter area, separate groups took possession of Tournai and Cambrai and reached the Somme. These Franks along the coast were divided into many small kingdoms. One of the better-known groups established itself in and around the *urbs* of Tournai; its leader (*regulus*) was Childeric (d. *c.* 481/482), who traditionally is regarded as a close relative in the male line of Merovech, eponymous ancestor of the Merovingian dynasty. Childeric placed himself in the service of the Roman Empire.

Ancestor of the Merovingian dynasty

Gaul and Germany at the end of the 5th century. Preceding the arrival of the Franks, other Germans had already entered Gaul. The area south of the Loire was divided between two groups. One, the Visigoths, occupied Aquitaine, Provence, and most of Spain. Their king, Euric (ruled 466–484), was the most powerful monarch in the West. The other group, the Burgundians, ruled much of the Rhône valley. In northern Gaul the Alemanni occupied Alsace and moved westward into the area between the Franks and Burgundians, while the first British immigrants established themselves on the Armorican Peninsula (now Brittany). Substantial parts of Gaul were ruled by Syagrius, a Roman king (*rex*), with his capital at Soissons.

In spite of the German influx, Gaul, which had been part of the Roman Empire for about 500 years, remained thoroughly Romanized. Because many of its administrative institutions withstood the crisis of the 5th century, Gaul's traditional Roman civilization survived, at least in attenuated form, especially among the aristocratic classes. The core of political, social, economic, and religious life remained in the *civitas* with the *urbs* at its heart. In addition, the Germans themselves were, to varying degrees, affected by this civilization. This influence was stronger among the Burgundians and the Visigoths, who had lived within the empire for a longer time and had intermingled with other Germanic peoples to a great extent, than it was among the Franks and Alemanni, who had only recently entered the empire. The Burgundians and Visigoths adopted a heretical form of Christianity—Arianism. The Franks and Alemanni remained pagan and preserved limited contacts with Germans living outside the boundaries of the Roman Empire.

Survival of Roman civilization

In effect, the Germanic peoples who penetrated into Roman Gaul were but a small segment of the Germanic world. The northern Germans (Angles, Jutes, Saxons, and Frisians) still occupied the coastal regions of the North Sea east of the Rhine; the Thuringians and Bavarians divided the territory between the Elbe and Danube; the Slavic world began on the opposite bank of the Elbe.

THE MEROVINGIANS

Clovis. Clovis (ruled 481/482–511), the son of Childeric, unified Gaul with the exception of areas in the southeast.

Frankish expansion and the unification of Gaul. During the years following his accession, Clovis consolidated the position of the Franks in northern Gaul. In 486 he defeated Syagrius, the last Roman ruler in Gaul, and in a series of subsequent campaigns with strong Gallo-Roman support occupied an area situated between the Frankish kingdom of Tournai, the Visigothic and Burgundian kingdoms, and the lands occupied by the Rhenish (Ripuarian) Franks and the Alemanni, removing it from imperial control once more. It was probably during this same period that he eliminated the other Salian kings. In a second phase he attacked the other Germanic peoples living in Gaul, with varying degrees of success. An Alemannian westward push was blocked, probably as a result of two campaigns—one conducted by the Franks of the kingdom of Cologne in about 495–496 at the Battle of Tolbiacum (Zülpich), the second by Clovis in about 506, after his annexation of Cologne. Clovis thus extended his authority over most of the territory of the Alemanni. Some of the former inhabitants sought refuge in Theodoric's Ostrogothic kingdom. After his conversion to Roman Christianity about 498, Clovis absorbed the region between the Seine and the Loire (including Nantes, Rennes, and Vannes) and then moved against the Visigothic kingdom. He defeated Alaric II at Vouillé (507). He annexed Aquitaine, between the Loire, Rhône, and Garonne, as well as Novempopulana, between the Garonne and the Pyrenees. Opposed to a Frankish hegemony in the West, Theodoric intervened on behalf of the Visigothic king. He prevented Clovis from annexing Septimania, on the Mediterranean between the Rhône and the Pyrenees, which the Visigoths retained, and occupied Provence. In addition, Clovis eliminated various Frankish kinglets in the east and united the Frankish people under his own leadership.

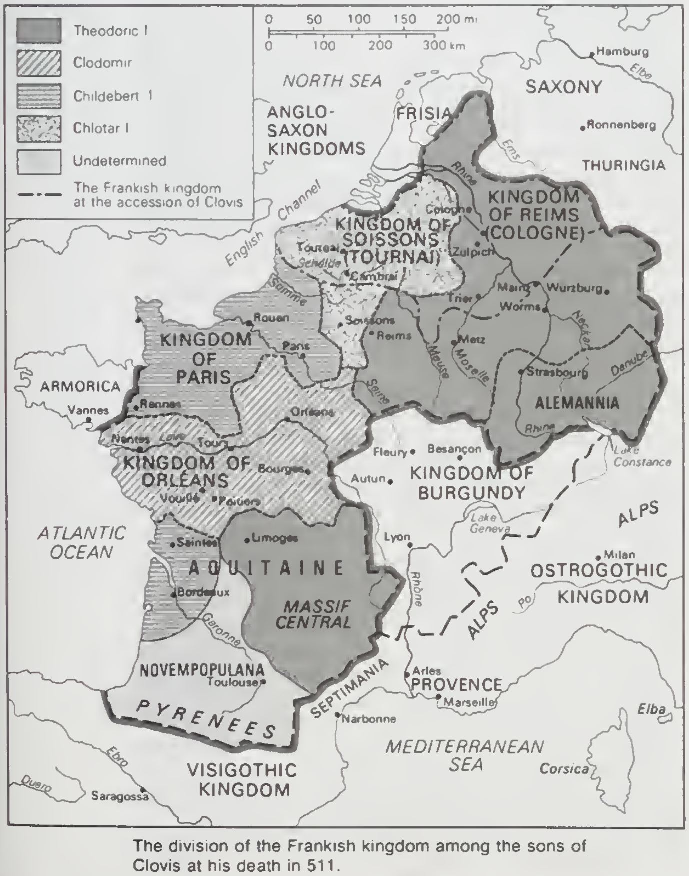
Clovis established Paris as the capital of his new kingdom, and about 507–508 he received from the emperor an honorary consulship and the right to use the imperial insignia. These privileges gave the new king legitimacy of sorts and were useful in gaining the support of his Gallo-Roman subjects.

Triumph of Roman Catholicism in Gaul

The conversion of Clovis. Clovis came to believe that his victory at Tolbiacum in 496 was due to the help of the Christian God, whom his wife Clotilda had been encouraging him to accept. With the support of Bishop Remigius of Reims, a leader of the Gallo-Roman aristocracy, Clovis converted with some 3,000 of his army. Clovis' conversion assured the Frankish king of the support not only of the ecclesiastical hierarchy but in general also of Roman Christians—the majority of the population. It also ensured the triumph in Gaul of Roman Christianity over paganism and Arianism and spared Gaul the lengthy conflicts that occurred in other Germanic kingdoms.

The sons of Clovis. Following the death of Clovis in 511, the kingdom was divided among his four sons. This partition was not made according to ethnic, geographic, or administrative divisions. The only factor taken into account was that the portions be of equal value (defined in terms of the royal fisc, which had previously been the imperial fisc, and tax revenues from land and trade, which were based upon imperial practices). Boundaries were poorly defined. The territory was divided into two general areas: one was the territory north of the Loire (the part of Gaul that was conquered earliest); the other, to the south in Aquitaine, was a region not yet assimilated. Theodoric I, Clovis' eldest son by one of his wives married in Germanic style before Clovis married Clotilda and converted to Christianity, received lands around the Rhine, Moselle, and upper Meuse, as well as the Massif Central; Clodomir, the Loire country to the other side of the Rhine (this kingdom was the only one not composed of separated territories); Childebert I, the country of the English Channel and the lower Seine and, probably, the region of Bordeaux and Saintes; Chlotar I, the old Frankish country north of the Somme and an ill-defined area in Aquitaine. Their capitals were centred in the Paris Basin, which was divided among the four brothers: Theodoric I used Reims; Clodomir, Orléans; Childebert I, Paris; Chlotar I, Soissons. As each brother died, the survivors partitioned the newly available lands among themselves. This system resulted in bloody competition until 558, when Chlotar I, after his brothers' deaths, succeeded in reuniting the kingdom under his own rule.

From R Grousset and E Leonard (eds), *Histoire Universelle*



The division of the Frankish kingdom among the sons of Clovis at his death in 511.

The conquest of Burgundy and southern Germany. In spite of these partitions, the Frankish kings continued their conquests. One of their primary concerns was to extend their dominion over the whole of Gaul. It took two campaigns to overcome the Burgundian kingdom. In 523 Clodomir, Childebert I, and Chlotar I, as allies of Theodoric, king of the Ostrogoths, moved into Burgundy, whose king, Sigismund, Theodoric's son-in-law, had assassinated his own son. Sigismund was captured and killed. Godomer, the new Burgundian king, defeated the Franks at Vézeronce and forced them to retreat; Clodomir was killed in the battle. Childebert I, Chlotar I, and Theodebert I, the son of Theodoric I, regained the offensive in 532–534. The Burgundian kingdom was annexed and divided between the Frankish kings. Following Theodoric's death in 526, the Franks were able to gain a foothold in Provence by taking advantage of the weakened Ostrogothic kingdom. The Franks were thus masters of all southeastern Gaul and had reached the Mediterranean. But, in spite of two expeditions (531 and 542: the siege of Saragossa), they were unable to gain possession of Visigothic Septimania. Also, at least a portion of Armorica in the northwest remained outside the Frankish sphere of influence. During this period, British colonization of the western half of the Armorican Peninsula was at its height.

Conquests of Thuringia and Bavaria

To the east, the Franks extended their domain in southern Germany, bringing Thuringia (*c.* 531 Chlotar I carried off Radegunda, a niece of the Thuringian king), the part of Alemannia between the Neckar and the upper Danube (after 536), and Bavaria under subjection. The latter was created as a dependent duchy in about 555. The Franks were less successful in northern Germany; in 536 they imposed a tribute on the Saxons (who occupied the area between the Elbe, the North Sea, and the Ems), but the latter revolted successfully in 555.

Theodebert I and his son, Theodebald, sent expeditions into Italy during a struggle between the Ostrogoths and Byzantines (535–554), but they achieved no lasting results.

The grandsons of Clovis. At the death of Chlotar I (561) the Frankish kingdom, which had become the most powerful state in the west, was once again divided, this time between his four sons. The partition agreement, based on that of 511, dealt with more extensive territories. Guntram received the eastern part of the former kingdom of Orléans, enlarged by the addition of Burgundy. Charibert I's share was fashioned from the old kingdom of Paris (Seine and English Channel districts), augmented in the south by the western section of the old kingdom of Orléans (lower Loire valley) and the Aquitaine Basin. Sigebert I received the kingdom of Reims, extended to include the new German conquests; a portion of the Massif Central (Auvergne) and the Provençal territory (Marseille) were added to his share. Chilperic I's portion was reduced to the kingdom of Soissons.

The death of Charibert (567) resulted in still a further partition. Chilperic, the principal beneficiary, received the lower Seine district, including a large tract of the English Channel coast. The remainder, most notably Aquitaine and the area around Bayeux, was divided in a complex manner; and Paris was subject to joint possession. The partitions of 561 and 567, which reaffirmed the division of Francia, were the sources of innumerable intrigues and family struggles, especially between, on the one hand, Intrigues and family struggles

Chilperic I, his wife Fredegund, and their children, who controlled northwestern Francia, and, on the other hand, Sigebert I, his wife Brunhild, and their descendants, the masters of northeastern Francia.

The shrinking of the frontiers and peripheral areas. These events undermined the Frankish hegemony. In Brittany the Franks maintained control of the eastern region but had to cope with raids by the Bretons, who had established heavily populated settlements in the western part of the peninsula. To the southwest the Gascons, a highland people from the Pyrenees, had been driven northward by the Visigoths in 578 and settled in Novempopulana; in spite of several Frankish expeditions, this area was not subdued. In the south the Franks were unable to gain control of Septimania; they tried to accomplish this by means of diplomatic agreements, which were buttressed by dynastic intermarriage, and by military campaigns occasioned by religious differences (the Visigothic kings were Arians). In the southeast the Lombards, who had recently arrived in Italy, made several raids on Gaul (569, 571, 574); Frankish expeditions into Italy (584, 585, 588, 590), led by Childebert II, were without result. Meanwhile the Avars, a people of undetermined origin who settled along the Danube in the second half of the 6th century, threatened the eastern frontier; in 568 they took Sigebert prisoner, and in 596 they attacked Thuringia, forcing Brunhild to purchase their departure.

The parceling up of the kingdom. Internal struggles resulted in the emergence of new political configurations. At the time of the partitions of 561 and 567, new political geographic units began to appear within Gaul. Austrasia was created from the Rhine, Moselle, and Meuse districts, which had formerly been the kingdom of Reims, and the areas east of the Rhône conquered by Theodoric and his son Theodebert; Sigebert I (d. 575) transferred its capital to Metz in order to take advantage of the income provided by trade on the Rhine. Neustria was born out of the partition of the kingdom of Soissons; a portion of the kingdom of Paris was added to it, thus endowing the area with a broad coastal section and making the lower Seine valley its centre. Its first capital, Soissons, was returned to Austrasia following the death of Chilperic I; its capital was later moved to Paris, which had been controlled by Chilperic. The kingdom of Orléans, without its western territory but with part of the old Burgundian lands added to it, eventually became Burgundy; Guntram fixed its capital at Chalon-sur-Saône. Aquitaine submitted to the Frankish kingdoms centred farther north in Gaul; its *civitates* were the object of numerous partitions made by sovereigns who regarded it as an area for exploitation. Aquitaine did not enjoy political autonomy during this period.

The failure of reunification (613–714). Territorial crisis was partially and provisionally averted during the first third of the 7th century.

Chlotar II and Dagobert I. Chlotar II, king of Neustria since 584, took control of Burgundy and Austrasia in 613 upon the brutal execution of Brunhild, and thus a united kingdom once again was created. He fixed his capital at Paris and, in 614, convoked a council there, at which he recognized the traditional prerogatives of the aristocracy (Gallo-Roman and Germanic) in order to gain their support in the governing of the kingdom. His son Dagobert I (ruled 629–639) was able to preserve this unity; he journeyed to Burgundy, where the highest political office, mayor of the palace, was maintained, to Austrasia, and to Aquitaine, which was given the status of a duchy. He thus recognized structures of imperial origin.

Dagobert had only limited success along the frontier. In 638 he placed the Bretons and the Gascons under nominal subjection, but ties with these peripheral regions were tenuous. He intervened in dynastic quarrels of Spain, entering the country and going as far as Saragossa before receiving tribute and quitting the country. Septimania remained Visigothic. On the eastern frontier there were incidents involving Frankish merchants and Moravian and Czech Slavs; aftcr the failure of a campaign conducted by Dagobert, with the assistance of the Lombards and Bavarians (633), the Slavs attacked Thuringia. The king reached an agreement with the Saxons, who would protect the eastern frontier in return for remission of a tribute they had paid since 536. Thus Dagobert used traditional imperial techniques to protect the frontiers with more or less Romanized barbarians.

The hegemony of Neustria. The territorial struggles began anew after 639. In Neustria, Austrasia, and Burgundy, power was in the hands of aristocratic leaders, called the mayors of the palace. Ebroïn, mayor of the palace in Neustria, attempted to unify the kingdom under his leadership but met with violent opposition. Resistance in Burgundy was led by Bishop Leodegar, who was assassinated in about 679. (He was later canonized.) Austrasia was governed by the Pepinid mayors of the palace; Pepin I of Landen was succeeded by his son Grimoald, who tried unsuccessfully to have his son, Childebert the Adopted, crowned king, and by Pepin II of Herstal (or Héristal), whom Ebroïn was briefly able to keep from power (*c.* 680).

Struggle between Neustria and Austrasia

Frankish hegemony was once more threatened in the peripheral areas, especially to the east where Austrasia was endangered. The Thuringians (640–641) and Alemanni regained their independence. The Frisians reached the mouth of the Schelde and controlled the towns of Utrecht and Dorestat; the attempted conversion of Frisia by Wilfrid of Northumbria had to be abandoned (*c.* 680). In southern Gaul, Duke Lupus changed the status of Aquitaine from that of a duchy to an independent principality.

Austrasian hegemony and the rise of the Pepinids. The murder of Ebroïn (680 or 683) reversed the situation in favour of Austrasia and the Pepinids. Pepin II, who defeated the Neustrians at Tertry in 687, reunified northern Francia under his own control during the next decade. Austrasia and Neustria were reunited under a Merovingian figurehead, but Pepin II governed by virtue of his position as mayor of the palace. At the same time, Pepin II partially restabilized the frontiers of northern Francia by driving the Frisians north of the Rhine and by restoring Frankish suzerainty over the Alemanni. But control of southern Gaul continued to elude Pepin II and his supporters. In the early 8th century, Provence became an autonomous duchy, while power in Burgundy was divided.

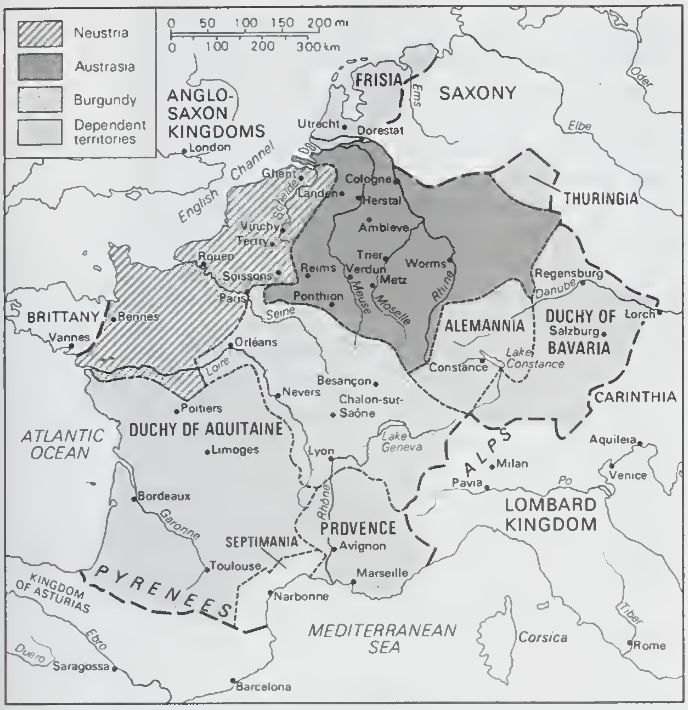
Pepin II

THE CAROLINGIANS

Representatives of the Merovingian dynasty continued to hold the royal title during most of the first half of the 8th century. They were captive monarchs, according to a contemporary biographer of Charlemagne. In actual fact, effective power was in the hands of the Pepinids, who, thanks to their valuable landholdings and loyal retainers, maintained a monopoly on the office of mayor of the palace. Because of their familial predisposition for the name Charles and because of the significance of Charlemagne in the family's history, modern historians have called them the Carolingian dynasty.

Charles Martel and Pepin III the Short. Pepin II's death in 714 jeopardized Carolingian hegemony. His heir was a grandchild entrusted to the regency of his widow, Plectrude. There was a revolt in Neustria, and Eudes, duke of Aquitaine, used the occasion to increase his holdings and make an alliance with the Neustrians. The Saxons crossed the Rhine and the Arabs crossed the Pyrenees.

Charles Martel. The situation was rectified by Pepin's illegitimate son, Charles Martel. Defeating the Neustrians at Amblève (716), Vincy (717), and Soissons (719), he made himself master of northern Francia. He then reestablished Frankish authority in southern Gaul, where the local authorities could not cope with the Islāmic threat; he stopped the Muslims near Poitiers (Battle of Tours; 732) and used this opportunity to subdue Aquitaine (735–736). The Muslims then turned toward Provence, and Charles Martel sent several expeditions against them. At the same time, he succeeded in reestablishing authority over the dissident provinces in the southeast (737–738) with the exception of Septimania. Finally, he reestablished his influence in Germany. In his numerous military campaigns he succeeded in driving the Saxons across the Rhine, returned the Bavarians to Frankish suzerainty, and annexed southern Frisia and Alemannia. He also encouraged missionary activity, seeing it as a means to consolidate his power; this undertaking was supported by the papacy,



The Frankish domains in the time of Charles Martel (boundaries approximate).

From G. Fournier, *L'Occident de la fin du V^e siecle a la fin du IX^e siecle*

which was beginning to seek support in the West. Missionaries east of the Rhine, most of whom were Anglo-Saxon (*e.g.,* Willibrord and Winfrid, also known as Boniface), made definite progress in their task.

Charles Martel's chief source of power

Charles Martel had supported a figurehead Merovingian king, Theodoric IV (ruled 721–737), but upon the latter's death he felt his own position secure enough to leave the throne vacant. His chief source of power was a strong circle of followers, who furnished the main body of his troops and became the most important element in the army because local dislocation of government had weakened the recruitment of the traditional levies of free men. He attached them to himself by concessions of land, which he obtained by drawing on the considerable holdings of the church. This gave him large tracts of land at his disposal, which he granted for life (*precaria*). He was thus able to recruit a larger and more powerful circle of followers than that surrounding any of the other influential magnates.

Pepin III the Short. At the death of Charles Martel (741), as was the custom, the lands and powers in his hands were divided between his two sons, Carloman and Pepin III the Short. This partition was followed by unsuccessful insurrections in the peripheral duchies—Aquitaine, Alemannia, and Bavaria.

Carloman's entrance into a monastery in 747 reunited Carolingian holdings. Pepin the Short, who had held de facto power over Francia, or the *regnum Francorum,* as mayor of the palace, now desired to be king. He was crowned with the support of the papacy, which, threatened by the Lombards and having problems with Byzantium, sought a protector in the West. The change of dynasty was accomplished in two stages: in 751, after obtaining the support of Pope Zacharias, Pepin deposed Childeric III; he then had himself elected king by an assembly of magnates and consecrated by the bishops, thus ending the nominal authority of the last Merovingian king, Childeric III, who had been placed on the throne in 743. The new pope, Stephen II (or III), sought aid from Francia; in 754 at Ponthion he gave Pepin the title patrician of the Romans, renewed the king's consecration, and consecrated Pepin's sons, thus providing generational legitimacy for the line.

As king, Pepin limited himself to consolidating royal control in Gaul, thus establishing the base for later Carolingian expansion. Despite Pepin's efforts, the situation at the German frontier was unstable. The duchy of Bavaria, which had been given to Tassilo III as a benefice, gained its independence in 763; several expeditions were unable to subdue the Saxons. On the other hand, Pepin achieved a decisive victory in southern Gaul by capturing Septimania from the Muslims (752–759). He broke down Aquitaine's resistance, and it was reincorporated into the kingdom (760–768). Pepin intervened in Italy twice (754–755; 756) on the appeal of the pope and laid the foundations for the Papal States. He exchanged ambassadors with the great powers of the eastern Mediterranean—the Byzantine Empire and the caliphate of Baghdad.

Charlemagne. Pepin III, faithful to ancient customs, divided his kingdom between his two sons, Charles (Charlemagne) and Carloman. On Carloman's death in 771 the kingdom was reunited. Charlemagne established the base of his kingdom in northeastern Francia (his preferred residence was Aachen [Aix-la-Chapelle]).

The conquests. Charlemagne extended considerably the territory he controlled and unified a large part of the Christian West; he followed no grand strategy of expansion, taking advantage, instead, of situations as they arose.

Territorial consolidation and conquests

Charlemagne consolidated his authority up to the geographic limits of Gaul. Though he put down a new insurrection in Aquitaine (769), he was unable to bring the Gascons and the Bretons fully under submission. He pursued an active policy toward the Mediterranean world. In Spain he attempted to take advantage of the emir of Córdoba's difficulties; he was unsuccessful in western Spain, but in the east he was able to establish a march south of the Pyrenees to the important city Barcelona. Pursuing Pepin's Italian policy, he intervened in Italy. At the request of Pope Adrian I, whose territories had been threatened by the Lombards, he took possession of their capital city, Pavia, and had himself crowned king of the Lombards. In 774 he fulfilled Pepin's promise and created a papal state; the situation on the peninsula remained unsettled, and many expeditions were necessary. This enlargement of his Mediterranean holdings led Charlemagne to establish a protectorate over the Balearic Islands in the western Mediterranean (798–799).

Charlemagne conquered more German territory and secured the eastern frontier. By means of military campaigns and missionary activities he brought Saxony and northern Frisia under control; the Saxons, led by Widukind, offered a protracted resistance (772–804), and Charlemagne either destroyed or forcibly deported a large part of the population. To the south, Bavaria was brought under Frankish authority and annexed. Conquests in the east brought the Carolingians into contact with new peoples—Charles was able to defeat the Avars in three campaigns (791, 795, 796), from which he obtained considerable booty; he was also able to establish a march on the middle Danube, and the Carolingians undertook the conversion and colonization of that area. Charles established the Elbe as a frontier against the northern Slavs. The Danes constructed a great fortification, the Dannevirke, across the peninsula to stop Carolingian expansion. Charles also founded Hamburg on the banks of the Elbe. These actions gave the Franks a broad face on the North Sea.

The Frankish state was now the principal power in the West. Charlemagne claimed to be defender of Roman Christianity and intervened in the religious affairs of Spain. Problems arose over doctrinal matters that, along with questions concerning the Italian border and the use of the imperial title, brought him into conflict with the Byzantine Empire; a peace treaty was signed in 810–812. Charles continued his peace policy toward the Muslim East: ambassadors were exchanged with the caliph of Baghdad, and Charles received a kind of eminent right in Jerusalem.

Charlemagne's coronation as emperor

The restoration of the empire. When by the end of the 8th century Charles was master of a great part of the West, he reestablished the empire in his own name. He was crowned emperor in Rome (Christmas Day, 800), by Pope Leo III. Charlemagne's powers in Rome and in relation to the Papal States, which were incorporated, with some degree of autonomy, into the Frankish empire, were clarified. Although his new title did not replace his royal titles, it was well suited to his preponderant position in the old Roman West. The imperial title indicates a will to unify the West; nevertheless, Charlemagne preserved the kingdom of Italy, giving the crown to one of his sons, Pepin, and made Aquitaine a kingdom for his other son, Louis. Emperors ruled over kings.

Louis I the Pious. Only chance ensured that the empire remained united under Louis I the Pious, the last surviving son of Charlemagne (the latter had anticipated the partitioning of his empire among his sons). The era of great conquests had ended, and, on the face of it, Louis's principal preoccupation was his relations with the peoples to the north. In the hope of averting the threat posed by the Vikings, who had begun to raid the coasts of the North Sea and the Atlantic Ocean, Louis proposed to evangelize the Scandinavian world. This mission was given to St. Ansgar but was a failure.

Louis's conception of the empire

During Louis's reign, the imperial bureaucracy was given great uniformity. Louis saw the empire, above all, as a religious ideal, and in 816 the imperial coronation, originally a secular ceremony, was complemented by a religious ceremony, the anointment, at which the pope presided. At the same time Louis the Pious took steps to regulate the succession so as to maintain the unity of the empire (*Ordinatio Imperii,* 817). His oldest son, Lothair I, was to be sole heir to the empire, but within it three dependent kingdoms were maintained: Louis's younger sons, Pepin and Louis, received Aquitaine and Bavaria, respectively; his nephew Bernard was given Italy.

The remarriage of Louis the Pious to Judith of Bavaria and the birth of a fourth son, Charles II the Bald, upset this project. In spite of opposition from Lothair, who had the support of a unity faction drawn from the ranks of the clergy, the emperor's principal concern was to create a kingdom for Charles the Bald. These divergent interests led to conflicts that weakened imperial prestige (in 833, abandoned by his followers at the Field of Lies, Louis the Pious was forced to make public penance at the church of Notre-Dame at Compiègne). The question of Aquitaine arose at the death of Pepin I, ruler there since 814; the emperor gave this subordinate kingdom to Charles, but the magnates rose up and proclaimed Pepin II, the son of the dead king.

The partitioning of the Carolingian empire. After the death of Louis I the Pious (840), his sons continued their plotting to alter the succession. Louis II the German and Charles II the Bald affirmed their alliance against Lothair I (Oath of Strasbourg, 842).

The Treaty of Verdun. Later the three brothers came to an agreement in the Treaty of Verdun (843). The empire was divided into three kingdoms arranged along a north–south axis: Francia Orientalis was given to Louis, Francia Media to Lothair, and Francia Occidentalis to Charles the Bald. The three kings were equal among themselves. Lothair kept the imperial title, but it had completely lost its universal character and had meaning only in a portion of the old empire.

The Carolingian empire and (inset) divisions after the Treaty of Verdun, 843.

The kingdoms created at Verdun. Until 861 the clerical faction tried to impose a government of fraternity on the descendants Charlemagne, manifested in the numerous conferences they held; but particularistic forces destroyed it.

Francia Media proved to be the least stable of the kingdoms, and the imperial institutions bound to it suffered as a result. In 855 the death of Lothair I was followed by a partition of his kingdom among his three sons: the territory to the north and west of the Alps went to Lothair II (Lotharingia) and to Charles (kingdom of Provence); Louis II received Italy and the imperial title. At the death of Charles of Provence (863), his kingdom was divided between his brothers Lothair II (Rhône region) and Louis II the German (Provence). After the death of Lothair II in 869, Lotharingia was divided between his two uncles, Louis the German and Charles the Bald. Louis, however, did not gain control of his share until 870. Charles was made master of the Rhône regions of the ancient kingdom of Provence. Louis II (d. 875) devoted most of his attention to fighting the Muslims who threatened the peninsula and the papal territories.

Viking invasions

In Francia Occidentalis Charles II the Bald was occupied with the struggle against the Vikings, who ravaged the countryside along the Scheldt, Seine, and Loire rivers. More often than not, the king was forced to pay for their departure with silver and gold. Aquitaine remained a centre of dissension. For some time (until 864) Pepin II continued to have supporters there, and Charles the Bald attempted to pacify them by installing his sons—first Charles the Young (ruled 855–866) and then Louis II the Stammerer (ruled 867–877)—on the throne of Aquitaine. The problems in Aquitaine were closely connected to general unrest among the magnates, who wished to keep the regional king under their control. By accumulating countships and creating dynasties, the magnates succeeded in carving out large principalities at the still unstable borders: Robert the Strong and Hugh the Abbot in the west; Eudes, son of Robert the Strong, in this same region and in the area around Paris; Hunfred, Vulgrin, Bernard Plantevelue, count of Auvergne, and Bernard of Gothia in Aquitaine and the border regions; Boso in the southeast; and Baldwin I in Flanders. Nevertheless, Charles the Bald appeared to be the most powerful sovereign in the West, and in 875 Pope John VIII arranged for him to accept the imperial crown. An expedition he organized in Italy on the appeal of the pope failed, and the magnates of Francia Occidentalis rose up. Charles the Bald died on the return trip (877). Charles's son, Louis II the Stammerer, ruled for only two years. At his death in 879 the kingdom was divided between his sons Louis III and Carloman. In the southeast, Boso, the count of Vienne, appropriated the royal title to the kingdom of Provence. The imperial throne remained vacant. The death of Louis III (882) permitted the reunification of Francia Occidentalis (except for the kingdom of Provence) under Carloman.

In Francia Orientalis royal control over the aristocracy was maintained. But decentralizing forces, closely bound to regional interests, made themselves felt in the form of revolts led by the sons of Louis the German. The latter had made arrangements to partition his kingdom in 864, with Bavaria and the East Mark to go to Carloman, Saxony and Franconia to Louis the Younger, and Alemannia (Swabia) to Charles III the Fat. Although Louis II the German managed to gain a portion of Lotharingia in 870, he was unable to prevent Charles the Bald's coronation as emperor (875).

When Louis the German died in 876, the partition of his kingdom was confirmed. At the death of Charles the Bald, Louis the German's son Carloman seized Italy and intended to take the imperial title, but ill health forced him to abandon his plans. His youngest brother, Charles III the Fat, benefited from the circumstances and restored the territorial unity of the empire. The deaths of his brothers Carloman (880) and Louis III the Younger (882) without heirs allowed him to acquire successively the crown of Italy (880) and the imperial title (881) and to unite Francia Orientalis (882) under his own rule. Finally, at the death of Carloman, son of Louis the Stammerer, Charles the Fat was elected king of Francia Occidentalis (885); the magnates had bypassed the last heir of Louis the Stammerer, Charles III the Simple, in his favour.

Charles the Fat avoided involving himself in Italy, in spite of appeals from the pope, and concentrated his attention on coordinating resistance to the Vikings, who had resumed the offensive in the valleys of the Scheldt, Meuse, Rhine, and Seine. He was unsuccessful, however, and in 886 had to purchase the Vikings' departure: they had besieged Paris, which was defended by Count Eudes. The magnates of Francia Orientalis rose up and deposed Charles the Fat in 887.

THE FRANKISH WORLD

Society. *Germans and Gallo-Romans.* The settlement of Germanic peoples in Roman Gaul brought people from two entirely different backgrounds into contact. Linguistic barriers were quickly overcome, for the Germans adopted Latin. At the same time, German names were preponderant. Although there were religious difficulties in those regions settled by peoples converted to Arianism (Visigoths, Burgundians), Clovis' conversion simplified matters. The Germans who settled in Gaul were able to preserve some of their own judicial institutions, but these were heavily influenced by vulgar Roman law. The first sovereigns committed the now Roman-influenced customs of the people to writing, in Latin (Code of Euric, *c.* 470–480; Salic Law of Clovis, *c.* 507–511; Law of Gundobad, *c.* 501–515) and occasionally had summaries of Roman rights drawn up for the Gallo-Roman population (Papian Code of Gundobad; Breviary of Alaric); this system of personality of the law, certain aspects of which survived well into the 9th century, was gradually replaced by a territorially based legal system. Multiple contacts in daily life produced an original civilization composed of a variety of elements, some of which were inherited from antiquity, some brought by the Germans, and many strongly influenced by Christianity.

The mixing of cultures

Social classes. The collapse of Roman imperial power and the influx of Germans did not destroy the old Roman senatorial and landed aristocracy; the 6th-century kings called on its members to serve in the administration. A sort of military aristocracy had existed among the Germans: at the time of their settlement within the empire, its members were given tax revenues and lands confiscated from the Gallo-Roman aristocracy or awarded from the fisc (royal treasury). The two groups fused rapidly. They shared a common life, discharging public and religious duties and frequenting the court. By the beginning of the 7th century there arose an aristocracy of office, whose signs of prestige were the possession of land and service to the king and church. This aristocracy increased in importance during the conflicts between the Merovingian sovereigns. The ascendance of the Pepinids, Carolingian rule, and the power struggles in the 9th century furnished these magnates, on whom those in power were dependent, with a means of enriching themselves and augmenting their political and social influence.

The aristocracy

Parallel to this class of lay magnates and largely drawn from the same families was an ecclesiastical aristocracy, which was one both of office and of land. The church found itself in possession of a vast landed fortune. At the beginning of the 7th century, at least, the church frequently benefited from immunity, and governmental rights were conferred on abbots or bishops.

A class of small and middle-sized landholders apparently existed, about which little is known. It appears that both the power of the magnates and the practices born of the ancient patronage system, combined with extensive military service, had the effect of diminishing the size of this class.

During the Merovingian epoch, slavery, inherited from antiquity, was still a viable institution. Slaves continued to be obtained in war and through trade. But the number of slaves decreased under the influence of the church, which encouraged manumission and sought to prohibit the enslavement of Christians. Under the Carolingians, the slaves in Gaul formed only a residual class, although the slave trade was still active. Taken increasingly from the Slavic territories (the term *slavus* replaced the traditional *servus*), slaves were a commodity for trade with the Muslim lands of the Mediterranean.

Vassalage

Diffusion of political power. During the period of insecurity and turbulence that marked the end of the Merovingian epoch, bonds of personal dependence, present in both Roman and Germanic institutions, can be seen to compete with weakened governmental institutions. In the 7th century these bonds took one of two forms: commendation (a free man placed himself under the protection of a more powerful lord for the duration of his life) and precarious contract (a powerful lord received certain services in return for the use of his land for a limited time under advantageous conditions). In the 8th century the Pepinids increased their personal circle of followers. Charlemagne attempted to encompass the entire free population of his empire within a vassalic relationship. He encouraged an increase in the number of royal vassals and gave them administrative functions. During the 9th-century power struggles, however, some administrative offices became hereditary, though this represented a distortion of the vassalic relationship. In addition, before the end of the century a man could place himself in vassalage to several lords. Finally, the usurpation of governmental powers led to the formation of territorial principalities, resulting in a great weakening of royal authority.

Institutions. The institutions of government underwent great changes under the Frankish monarchs.

Kingship. Kingship was the basic institution in the Merovingian kingdom. Since Clovis' reign, the power of the king had extended not only over a tribe or tribes but also over a territory inhabited by Germans of divergent backgrounds and by Gallo-Romans as well. The king exercised power with legal limitations, which, when violated, led to efforts to reestablish political equilibrium by means of civil war, assassination, and an appeal to God and the saints. Royal power was dynastic and patrimonial. The Frankish kings successfully eliminated the Germanic practice of the magnates electing the king (the Frankish king was content to present himself to the magnates who acclaimed him) and accepted the hereditary principle as a personal right. The kings partitioned the kingdom at each succession. Royal power also had a sacred aspect; under the Merovingians the external sign of this was long hair.

Changes in the Frankish monarchy

The nature of the Frankish monarchy was profoundly changed during the Carolingian epoch. When Pepin III the Short restored the office of king in his own name, he had himself consecrated first by a bishop and then by the pope. This rite, of biblical origin, had already been adopted by the Visigoths; it gave Christian legitimacy to royal authority because it reinforced the religious character of the monarchy and signified the king's receipt of special grace from God. The king was permitted to reign and was given stature above the common level because of this grace. Acclamation by the magnates became a pledge of obeisance to a king whom God had invested with power.

To this new royal status Charlemagne added the title of emperor, which had not been held by a ruler in the West since 476. He adopted this title as a concession to the situation at the time. It was conferred in the course of a ceremony that, in spite of the presence of the pope, was of secular character. Among the clerical ranks that formed the entourage of the new emperor, the revival of the empire was regarded as a magistracy conferred by God in the interests of western Christianity and the church; imperial authority was considered a kind of priesthood, and its bearer was obligated to lead and protect the faithful. This idea reached fruition under Louis the Pious, who introduced the ceremony of anointing as part of the investiture; this ritual furnished the pope with the means for gaining a noteworthy role in the designation of the emperor. His role increased because, in spite of all the efforts of the clergy to maintain the integrity of the empire, the imperial title was returned to Italy. Later Carolingian emperors were designated on the basis of the interests and actions of the papacy.

The central government. By the time of Clovis, the ancient Germanic assembly of free men participated only in the conduct of local affairs and was consigned largely to a military role. Within each kingdom, the king's court, of Roman imperial origin but adapted and modified by the Frankish sovereigns, encompassed domestic services (treasury, provisioning, stables, clergy), a bureau of accounts, and a military force. The court was presided over by three men—the seneschal, the count of the palace, and, foremost, the mayor of the palace, who also presided over the king's estates. They traveled with the king, who, while having various privileged places of residence, did not live at a fixed capital. Only under Charlemagne did this pattern begin to change; while not abandoning the itinerant life, Charlemagne nonetheless wished to make Aachen the centre of his state. It was there that he constructed a vast palace, based upon a Roman model.

Local institutions. Except in the north, which was divided into districts called *pagi,* the Merovingians continued to use the city (the Roman *civitas*) as the principal administrative division. A count was installed in each *pagus* and city (*urbs*) and delegated financial, military, and judicial authority. Groups of counts were occasionally placed under the authority of a duke, whose responsibilities were primarily military.

The development of institutions in the Carolingian age. The Carolingians contented themselves with refining their administrative system in order to strengthen royal control and to solve the problems posed by a large empire. The kingdom's cohesion was augmented by an oath of fidelity, which Charlemagne exacted from every free man (789, 793, 802), and by the publication of legislation—the capitularies—which regulated the administration and exploitation of the kingdom. In the most exposed border areas, local governments—the marches—were established.

In order to offset the power of the counts, the episcopate was given a central role in the administration. Charlemagne extended the use of the *missi dominici*—*i.e.,* envoys who also served as liaisons between the central government and local agents and who were responsible for keeping the latter in line. In order to strengthen his control over the population, Charlemagne attempted to develop intermediary bodies; he tried to use both vassalage and immunity as means of government—in the first instance by creating royal vassals and giving them public offices and in the second by controlling protected institutions such as monasteries and the Jewish community.

Predominance of the estate

Economic life. Agriculture was the principal economic activity, and during the entire Frankish age the great estate, inherited from antiquity, remained the predominant characteristic of rural life. These estates were the residence and principal source of income of the aristocracy. The estates appear to have long been placed under cultivation by servile labour, which was abundant at the time. The heavy work was done with the assistance of day labourers. A portion of the land, however, was given to the tenants—the *coloni*—who were compelled to pay annual charges. With the decline in slavery at the end of the Merovingian era, the number of tenancies was increased, and tenants were compelled to render significant amounts of labour to cultivate land held directly by the lord. This evolved into a bipartite system, which was not adopted throughout the Frankish empire but was most widespread between the Loire and the Rhine.

Trade. Despite the Islāmic conquests, Mediterranean commerce did not decline abruptly. In Gaul, such goods as papyrus, oil, and spices were imported from the East, and there were numerous colonies of Syrians. Currency continued to be based on the gold standard, and imperial units were still used. All signs, moreover, point to the existence of manufacturing for trade (marble from Aquitaine, Rhenish glass, ceramics).

During the Carolingian age, Mediterranean trade no longer occupied a primary place in the economy. The adoption of a new monetary system based on silver along with a reduction in the number of Oriental goods and merchants are signs of the change. After the 7th century, trade among the countries bordering the English Channel and the North Sea and in the Meuse valley increased steadily. The Scandinavians, with their great commercial centres at Birka in Sweden and Hedeby in Denmark, were both pirates and traders; they established new contacts between East and West.

In addition to this large-scale commerce there was agriculturally based local trade. The number of markets increased, and market towns began to appear alongside the former Gallo-Roman cities, which survived as fortresses and population centres and served as the basis for religious organization and political administration.

Royal sources of income

Frankish fiscal law. The Frankish fiscal system reflected the evolution of the economy. Frankish kings were unable to continue the Roman system of direct taxation of land as the basis for their income. Their principal sources of income were the exploitation of the domains of the fisc (royal treasury), war (booty, tribute), the exercise of power (monetary and judicial rights), and the imposition of *telonea* (taxes collected on the circulation and sale of goods), the number of which was increased by the kings.

The church. The episcopate and the diocese were practically the only institutions to survive the collapse of Roman imperial power largely unchanged. During the German conquest many bishops played important roles in defending the population. During the Frankish era bishops and abbots occupied a socially prominent position because of both their great prestige among the people and their landed wealth.

Institutions. The organization of the secular church took its final form under the Merovingian and Carolingian kings. The administrative bodies and the hierarchy of the early Christian church were derived from institutions existing during the late Roman Empire. In principle, a bishop was responsible for the clergy and faithful in each district (*civitas*). The bishop whose seat was in the metropolitan city had preeminence and was archbishop over the other bishops in his archdiocese. The monarchy dominated the church. Kings most often appointed bishops from among their followers without regard for religious qualifications; the metropolitan see was often fragmented in the course of territorial partitions and tended to lose its importance, and the church in Francia tended to withdraw more and more from papal control despite papal attempts to reestablish ties.

The first Carolingians reestablished the ecclesiastical hierarchy. They restored the authority of the archbishops and established cathedral chapters so that the clergy living around a bishop were drawn into a communal life. They also maintained the right to nominate bishops, whom they considered agents of the monarchy.

During the 4th and 5th centuries success at converting the countryside made it necessary for the bishops to divide the dioceses into parish churches. Initially there was a limit of between 15 and 40 of these per diocese. In the Carolingian era they were replaced by small parish churches better suited to the conditions of rural life.

Monasticism. Monasticism originated in the East. It was introduced in the West during the 4th century and was developed in Gaul, mainly in the west (St. Martin of Tours) and southeast (St. Honoratus and St. John Cassian). The earliest monasteries lacked a communal form of discipline; eremitism was widespread. In the 6th century, monasteries throughout Gaul increased, and efforts were made to impose rules. The Irish monasticism introduced by St. Columban (*c.* 543–615) was influential in the 7th century, but it was later superseded by the Benedictine rule, introduced from Italy. The monasteries suffered from the upheavals affecting the church in the 8th century. The Carolingians attempted to reform the monasteries. Louis the Pious, acting on the advice of St. Benedict of Aniane, imposed the Benedictine rule; it became a characteristic feature of western monasticism. The Carolingians, however, continued the practice of having lay abbots.

Education. In the 6th century, especially in southern Gaul, the aristocracy and, consequently, the bishops drawn from it preserved an interest in traditional classical culture. Beginning in the 7th century, the Columbanian monasteries insisted on the study of the Bible and the celebration of the liturgy. In the Carolingian era these innovations shared the focus of education with works of classical antiquity.

Religious discipline and piety. One characteristic of the church in the 6th century was frequent councils to settle questions of doctrine and discipline. The conciliar institution declined, leading to liturgical anarchy and a moral and intellectual crisis among the clergy. Charlemagne and Louis the Pious attempted to impose a uniform liturgy, inspired by the one used at Rome. They also took measures to raise the standard of education of both clerics and the faithful.

The cults of saints and relics

The development of the cults of saints and relics was an important part of religion. Commerce in relics developed, with Rome as one of the key centres. The number of pilgrimages increased. The desire on the part of the faithful to be buried near relics changed funeral practices. Ancient cemeteries were abandoned, and burials in or near churches (burials *ad sanctos*) increased.

The influence of the church on society and legislation. The progressive Christianization of society influenced Frankish institutions significantly. The introduction of royal consecration and the creation of the empire afforded the clergy an opportunity to elaborate a new conception of power based on religious principles. The church was involved in trying to discourage slavery and in ameliorating the legal condition of those enslaved. It was during the Carolingian period that, in reaction to the polygamy practiced in German society, Christian doctrines of marriage were more strictly formulated.

Merovingian literature and arts. During the entire 6th century many writers, inspired by classical tradition, produced works patterned on antique models; such writers included Sidonius Apollinaris (d. *c.* 488), Gregory of Tours (d. 594/595), and Venantius Fortunatus (d. *c.* 600). The writing of saints' lives—hagiography—became the most widespread literary genre of the period. Nevertheless, the standard of literature continued to decline, becoming more and more conventional and artificial. The use of popular Latin became more common among writers.

Religious architecture remained faithful to the early Christian model (churches of basilican type, baptisteries, and vaulted mausoleums with central plans). Because of the development of the cult of saints and the practice of burying *ad sanctos,* mausoleums became common in churches. As had been the case in antiquity, marble was the principal sculptural material. In the Pyrenees, sculptors produced capitals and sarcophagi in antique style, which they exported throughout Gaul; these workshops reached their zenith in the 7th century. The development of the art of metalwork (fibulae, buckles) was another characteristic of the Merovingian age. Germanic craftsmen adapted Roman techniques (*e.g.,* cloisonné and damascene work). A new aesthetic standard, characterized by the play of colour and the use of stylized motifs, eventually predominated.

The Carolingian renaissance

Carolingian literature and arts. A renaissance movement occurred during the general renovation undertaken by the Carolingian monarchs; they supported the movement as an aid to religious reform and as a means to enhance their own prestige. The origins of the movement lie deep in the 7th and 8th centuries. It received great stimulus, however, when the growth of the empire brought the Franks into contact with lands where a higher cultural standard had been maintained and the antique tradition was still viable (Ireland, Italy, and Anglo-Saxon England). The Carolingian sovereigns attracted foreigners (*e.g.,* the Anglo-Saxon Alcuin and the Lombard Paul the Deacon) who played a decisive role in this renewal.

After raising the standard of the clergy, Charlemagne assembled a group of scholars at his court. Although, contrary to legend, there was no formal school established in the imperial palace, there were numerous schools opened in the vicinity of churches and monasteries. An attempt was also made to reform handwriting. Research was carried on simultaneously under the auspices of several monastic centres (most notably Tours) for the purpose of standardizing writing; this effort resulted in the adoption of a regular and uniform script (Carolingian minuscule). Improved teaching and a desire to imitate classical antiquity helped to revivify the Latin used by writers and scribes.

The imperial court was a hub of intellectual life. From it came works dedicated to the glory of the emperors, which were modeled on the examples of ancient authors. Important works include Einhard's *Vita Karoli Magni* (*Life of Charlemagne*), the Astronomer's *Vita Hludowici impera-*

toris (*Life of Louis the Pious*), Nithard's *Historiarum libri IV* (*History of the Sons of Louis the Pious*), and Hincmar's *De ordine palatii* ("On the Government of the Palace").

Regional cultures

Beginning in the mid-9th century, however, the kingdoms formed from the partitions of the empire saw a renaissance of regional cultures. The fact that the Oath of Strasbourg was drawn up in Romance and German is an early indication of this development. There is a striking contrast between the *Annales Bertiniani* ("Annals of St. Bertin"), written at the court of Charles the Bald, and the *Annales Fuldenses* ("Annals of Fulda"), written at the principal intellectual centre in Francia Orientalis. They are, respectively, the western and eastern narratives of the same events.

Some of the great imperial monuments erected during the Carolingian age (palace of Ingelheim, palace of Aachen) reveal the permanence of ancient tradition in their regular plans and conception. The churches were the subjects of numerous architectural experiments; while some were constructed on a central plan (Germigny-des-Prés, Aachen with its internal octagon shape), most remained faithful to the traditional T-shape basilican type. Liturgical considerations and the demands of the faith, however, made certain modifications necessary, such as crypts on the east or a westwork, or second apse on the west. These church buildings afforded architects an opportunity to make experiments in balancing the arches. The extension of the vaults over the entire church and the more rational integration of the annexes and church proper gave rise to Romanesque architecture.

The buildings of the period were richly decorated with paintings, frescoes, painted stucco, and mosaics in which figural representation increasingly replaced strictly ornamental decoration. North Italian ateliers were popularizing the use of interlace (*i.e.,* ornaments of intricately intertwined bands) in chancel decoration. Sumptuary arts became more common, especially illumination, ivory work, and metalwork for liturgical use (reliquaries).

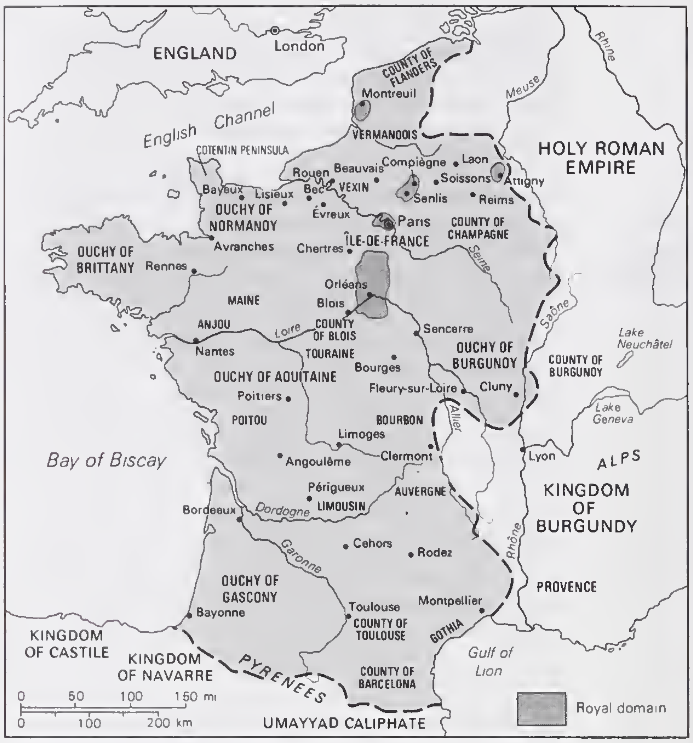
The emergence of France

From the 9th to the 11th century the peoples and lands dominated by west Frankish kings were transformed. The Carolingian protectorate of local order collapsed under the pressures of external invasions and internal usurpations of power. Growing populations and quickening economies were reorganized in principalities whose leaders struggled to carry on the old programs of kings, bishops, and monks; one of these lands, centred on the Paris-Orléans axis and later known as the Île-de-France, was the nucleus of a new dynastic kingdom of France. This kingdom may be spoken of as Capetian France (the first king of the new dynasty having been Hugh Capet), but it was not until the 13th century that this France came to approximate the modern nation in territorial extent. The emergence of a greater France as a social and cultural entity preceded the political expansion of Capetian France; already in the 12th century crusaders, when speaking of "Franks" from Romance-speaking lands, meant something like "Frenchmen," while the persistence of old boundaries between populations of Romance and Germanic speech perpetuated the idea of a greater west Frankland.

FRENCH SOCIETY IN THE EARLY MIDDLE AGES

Social and political order. A foremost circumstance of the later 9th and 10th centuries was the inability of the west Frankish kings to keep order. The royal estates that had theretofore supported them, mostly in the north and east, were depleted through grants to retainers uncompensated by new acquisitions. Hindered by poor communications, the kings lost touch with lesser counts and bishops, while the greater counts and dukes strove to forge regional clienteles in fidelity to themselves. These princes (as they were called) were not rebels. More often allied with the king than not, they exercised regalian powers of justice, command, and constraint; it was typically they who undertook to defend local settlements and churches from the ravages of Magyars invading from the east, of Muslims on Mediterranean coasts, and of Vikings from northern waters.



France in 987.

Viking invasions

Of these invaders the Northmen, as contemporaries called the Vikings, were the most destructive. They raided landed estates and monasteries, seizing provisions and movable wealth. Striking as far inland as Paris by 845, they attacked Bordeaux, Toulouse, Orléans, and Angers between 863 and 875. From a base in the Somme estuary they pillaged Amiens, Cambrai, Reims, and Soissons. But they were drawn especially to the Seine valley. In 856–860 they laid waste the country around its lower reaches and repeatedly attacked Paris thereafter. Sometimes they were turned back by defenses but more often by payments of tribute. After 896 the invaders began to settle permanently in the lower Seine valley, whence they spread west to form the duchy of Normandy. Maritime raiding continued into the 10th century, then subsided.

Lords such as the counts of Flanders, Paris, Angers, and Provence were well situated to prosper in the crisis. They were often descended from or related to Carolingian kings. Adding protectorates over churches to their inherited offices, domains, and fiefs while acquiring other lordships and counties through marriage, they built up principalities that were as precarious as they were powerful. The lords tried to avoid dismemberment of the patrimony by limiting their children's right of succession and marriage, but it was only in the 12th century that these dynastic principles came to prevail in the French aristocracy. The princes, moreover, found it almost as hard as the kings to secure their power administratively. They exploited their lands through servants valued less for competence than for fidelity; these servants, however, were men who tended to think of themselves as lords rather than agents. This tendency was especially marked among the masters of castles (castellans), who by the year 1000 were claiming the power to command and punish as well as the right to retain the revenues generated from the exercise of such power. In this way was completed a devolution of power from the undivided empire of the 9th century to a checkerboard of lordships in the 11th—lordships in which the control of castles was the chief determinant of success.

Castellans

This fragmented polity was a feudal regime; at every level lords depended on the services of sworn retainers who were usually rewarded with the tenures of lordship called fiefs (*feudum-a*). In the 9th century fiefs were not yet numerous enough to undermine the public order protected by kings and their delegates. Indeed, fiefs were at first rewards for public service made from fiscal (royal) lands; this practice persisted in the south into the 11th century. By then, however, castles, knights, and knights' fiefs were multiplying beyond all control, resulting in a fracturing of power that few princes succeeded in reversing before 1100. Counts were unwilling to admit that their counties were fiefs or that they owed the same sort of allegiance to kings or dukes as their vassals did to them. Tainted with servility as well as with the brutality of needy knights on the make, vassalage was slow to gain respectability. The multiplication of fiefs was a violent process of subjugating free peasants and abusing churches.

Economic expansion. The population, still overwhelmingly agrarian, was growing from about 900 AD, probably most rapidly in the north, where more flexible schemes of crop rotation led to better harvests. Some peasants retained their independence, as in the Massif Central and the Pyrenees, but they were not much envied; still, small free properties nowhere entirely disappeared. Most peasants, however, were organized in subjection to lords—bishops, abbots, counts, barons, or knights—whose estates assumed diverse forms. In northern France lords typically reserved the proceeds of a domain worked by tenants, who had their own parcels of land to live on. Among such tenants were free men and slaves as well as a sizable intermediate estate of incompletely free villagers. Increasing productivity stimulated the improvement of roads and bridges, trade, and the growth of towns as well as competition for the profits of agrarian lordship. After about 1050, townspeople, especially merchants, sought to free themselves from the arbitrary lordship of counts and bishops, usually peaceably, as at Saint-Omer, but occasionally in violent uprisings, as at Le Mans and Laon.

The Cistercian order

Religious and cultural life. The Christian church was badly disrupted by the invasions. In Normandy five successive bishops of Coutances resided at Rouen, far from their war-torn district, which had lapsed into paganism. Elsewhere standards of clerical deportment declined, threatening the moral leadership by which Carolingian prelates had supported public order. Renewal came in two influential forms. First, monks in Burgundy and Lorraine were inspired to return to a strict observance of the Benedictine rule and thereby to win the adherence of lay people anxious to be saved. The monastery of Cluny, founded in 910 by a duke of Aquitaine with a bad conscience, not only stimulated a newly penitential piety that radiated beyond its walls but also encouraged reforms in other monastic houses. In the 11th century Cluny came to direct an order of affiliated monasteries that extended throughout France and beyond. Cluny's religious hegemony was challenged only in the 12th century with the rise of a yet more ascetic Benedictine observance, of which St. Bernard of Clairvaux (1090–1153) was the great proponent. Centred at Cîteaux in Burgundy (whence the appellation Cistercian), this movement combined ascetic severity with introspective spirituality and economic self-sufficiency. A newly personal devotionalism was diffused from monastic cloisters into lay society.

Second, the bishops, in the absence of royal leadership, renewed Carolingian sanctions against violence. The Peace of God was instituted in synods of southern France in the later 10th century. It was an effort, solemnized in ritual processions and oaths, to restrain the increasing number of knights from pillaging peasants and churches. It was supplemented from the 1020s by the Truce of God, which forbade fighting on certain days or during certain seasons of the year and which helped to mold a new conception of the knight as a Christian warrior prohibited from shedding the blood of Christian people. Warmly embraced by the Cluniac pope Urban II when he preached the First Crusade at Clermont in 1095, this idea contributed to a new ideal of knighthood as an honourable estate of Christian leadership. When young princes were dubbed to knighthood in the 12th century, they assumed a mode of respectability fashioned by the church; this eased the way for lesser knights to be recognized as nobles as well.

Peter Abelard

The growing wealth and stability of regional societies, as in Burgundy, Flanders, and Normandy, encouraged new impulses in the arts and letters. Cathedral churches supported scholars who revived the traditional curriculum of learning, stressing reading, writing, speaking, and computation. Fulbert of Chartres (d. 1028) was fondly remembered as a humane teacher by students who often became teachers themselves. A century later famous masters could be found at Laon and Paris as well as (probably) at Chartres, attracting young clerics to their lectures in swelling numbers. The Breton Peter Abelard (1079–1142) taught and wrote so brilliantly on logic, faith, and ethics that he established Paris' reputation for academic excellence. Traditional pursuits of contemplative theology and history gave way to new interests in logic and law. Men trained in canon and Roman law found their way increasingly into the service of kings, princes, and bishops.

Everywhere churches in Romanesque style were built, and they continued to be built in the south long after some architects, like Suger at Saint-Denis in the 1140s, introduced the new aesthetic of Gothic style. Lay culture found expression in vernacular epics, such as *The Song of Roland* in Old French, and the Provençal lyrics of southern France. These poems witness to diverse zones of linguistic evolution from spoken Latin; by the 12th century the *langue d'oïl* north of the Loire was broadly differentiated from the *langue d'oc* to the south. The cultural cleavage so marked ran deeper than language and was not entirely overcome by the spread of modern French from the *langue d'oïl.*

THE POLITICAL HISTORY OF FRANCE (C. 850–1180)

The fragmentation of political power meant that the kings of France were forced into rivalries, alliances, and conflicts with the princes, who were for many generations the real rulers of France.

Principalities north of the Loire. Outside of the dynastic royal domain (centred around Paris) the foremost northern powers were Flanders, Normandy, Anjou, Brittany, Blois-Champagne, and Burgundy.

The northernmost of these was Flanders, whose founder, Baldwin I Iron-Arm (862–879), managed not only to abduct the Carolingian king's daughter and marry her but also to win that king's approval as count of Ghent. His authority was consolidated under his son Baldwin II (879–918) and grandson Arnulf (918–965), the latter a violent and ambitious prince who undertook to restore the Flemish church as if he were an emperor. Fertile and precocious in trading activity, Flanders well supported such energetic lords; monks at Saint-Bertin and Ghent celebrated the dynastic feats of the counts.

In the time of Robert the Frisian (1071–93) efforts were made to systematize the count's lordship over castles as well as his fiscal rights, but the results fell short of giving the count effective sovereign power. When the foreign-born Charles the Good (1119–27) tried to pacify the county at the expense of lesser knightly families, he was murdered. Stability together with a new and centralized mode of fiscal accountancy was achieved by Thierry of Alsace (1128–68) and his son Philip (1163–91). Toward 1180 Flanders was a major power in northern France.

Normandy

The duchy of Normandy was created in 911, when the Viking chieftain Rollo (Hrolf) accepted lands around Rouen and Evreux from King Charles III the Simple. With its pastures, fisheries, and forests, this old land was a rich prize, and Rollo's successors extended their domination of it aggressively. Early Norman history, however, is more obscure than Flemish, lacking the records that only Christian clerics could write. The acquisitions of the second duke of Normandy, William I Longsword (927–942), were threatened when he was murdered by Arnulf I of Flanders in 942. It was only in the reign of his son Richard I (942–996) that something like administrative continuity based on succession to fiscal domains and control of the church was achieved. The dukes (as they then came to be styled) allied with the ascendant duke Hugh Capet had little to lose from the latter's accession to the kingship in 987; it was at this time that a new Norman aristocracy in ducal control took shape. Under Robert I the Devil (1027–35) agrarian and commercial prosperity favoured the multiplication of castellanies and knights, and Duke William II (1035–87; William the Conqueror) had to put down a dangerous rising of Norman barons and castellans in 1047 before proceeding, surely in deliberate consequence, to establish a firmly central control of castles that was without precedent in France. His conquest of England in 1066 made William the most powerful ruler in France. At the same time knights from lesser elite families in Normandy were establishing territorial lordships in southern Italy.

Norman ducal lordship was crude but effective. Under Henry I (1106–35) a unified exploitation of patronage, castles, and revenues was developed for the kingdom of England and the duchy of Normandy alike. Normandy passed to Henry's son-in-law Count Geoffrey of Anjou in 1135 and to his grandson Henry II (1154–89), in whose time it became the heartland of an Angevin dynastic empire.

Anjou, in the lower Loire valley, was among the lands delegated to Robert the Strong in 866. In the 10th century a series of vigorous counts established a dynastic patrimony that expanded under the great Fulk Nerra (987–1040) and his son Geoffrey Martel (1040–60) to include Maine and Touraine. Strategically situated, this principality prospered in its early times of external danger, but it was surrounded by aggressive dynasts; the control of castles and vassalic fidelities were the count's somewhat precarious means of power.

Brittany, to the west of Anjou and Normandy, was set apart by its strongly Celtic tradition. It achieved identity in the 9th century under the native leader Nomenoë, who seized Nantes and Rennes in defiance of Charles the Bald. His successors, badly battered by the Vikings, were recognized as dukes in the 10th century but were unable to consolidate their power over lesser counts and castellans. With little more than an unenvied independence, the duchy persisted in the 12th century when a series of succession crises enabled King Henry II of England to subject it to the Plantagenet domains. Only after 1166 were the Bretons to feel the impact of systematic territorial administration.

The area around Blois, to the east of Touraine, had also been entrusted to Robert the Strong and remained in his family's hands until about 940, when Theobald the Old seized control of it and founded a line of counts of Blois. His successors, notably the fearsome Eudes II (996–1037), annexed the counties of Sancerre (1015) and Champagne (1019–23), thereby creating a principality comparable in strength to Flanders and more threatening to the king, whose patrimonial domains it encircled. A dynastic aggregate lacking natural cohesion, Blois-Champagne achieved its greatest strength under Theobald IV the Great (II of Champagne, 1125–52), who was a formidable rival of Kings Louis VI and Louis VII. The main lands were divided under his sons Theobald V (1152–91) and Henry (1152–81), themselves prestigious lords; and the Champagne of Henry the Liberal was among the richest, best organized, and most cultured French lands of its day.

Burgundy

Finally, there was Burgundy, to the south of Champagne (not to be confused with the old kingdom and the later imperial county of Burgundy), which first achieved princely identity under Richard the Justiciar (880–921). Defeating Magyars and Vikings as well as exploiting the rivalries of his neighbours, Richard was regarded (like his near contemporary Arnulf of Flanders) as virtually a king. Ducal power was contested and diminished thereafter, but it survived as the patrimony of a Capetian cadet family until 1361.

Thus, by the later 12th century, France north of the Loire consisted of several large principalities (some of them associated with the English crown), coexisting with each other and with the king, who struggled to impose his lordship on them.

The principalities of the south. South of the Loire emerged another set of lands: Provence, Auvergne, Toulouse, Barcelona, and Aquitaine.

Provence lay in what is now the southeastern corner of France; it was not part of the west Frankish domains. Included in the Middle Kingdom from 843, it passed to the kings of Burgundy after 879 and to the emperors in the 11th century. But it was local counts once again who won prestige as defenders against pillagers, in this case the Muslims, and profited from urban growth to establish a dynastic authority of their own. This authority was fractured in the early 12th century, when the houses of Barcelona and Toulouse secured portions by marriage; a cadet dynasty of Barcelona continued to rule the county until 1245.

The county of Barcelona, formed from a delegation of Frankish royal power in 878, came to dominate all other east Pyrenean counties in the 11th century. Prospering at the expense of the Muslims, Count Ramon Berenguer I (1035–76) reduced his castellans to submission (like his contemporary William in Normandy). His great-grandson Ramon Berenguer IV (1131–62) organized the strongest principality in the south. He and his successors acted as fully independent sovereigns, although the king of France retained a theoretical lordship over Barcelona until 1258.

Auvergne is the best example of a region whose masters failed to subordinate rival counts and castellans. Only a tradition of superior comital unity survived in the claims of two related counts whose patrimonies were absorbed by the crown in the 13th century.

Toulouse

Toulouse had been a centre of delegated Frankish power from the 8th century, but its pretension to princely status dated from 924, when Raymond III Pons (924–after 944) added control of coastal Gothia to that of Toulouse and its hinterland. Dynastic continuity, here as elsewhere, however, was badly interrupted, and none of the succeeding counts was able to organize a coherent lordship. Raymond IV of Saint-Gilles (1093–1105) acquired the crusader land of Tripoli (Syria), but he and his successors were weakened at home by conflicts with Barcelona and Aquitaine.

The duchy of Aquitaine might at first have seemed the most promising of all these principalities. A kingdom in the 9th century, it was reconstituted under William the Pious (d. 926) and again, more imposingly, under William V (995–1029), who was acclaimed as one of the greatest rulers of his day. Yet his power depended on lordships and alliances rather than on administration, and so the situation remained in the 12th century, when the vast but flabby duchy was conveyed by the marriages of its heiress Eleanor successively to the kings of France and England.

Of these principalities only Barcelona had achieved territorial cohesion and cultural unity by the later 12th century; it was then becoming known as Catalonia. The others, less toughened by external invasion and less resistant to the Cathari (or Albigensian) religious heresy from within, were vulnerable to an expanding Capetian monarchy.

The monarchy. The kingdom of France was descended directly from the west Frankish realm ceded to Charles the Bald in 843. Not until 987 was the Carolingian dynastic line set aside, but there had been portentous interruptions. The reunited empire of Charles the Fat (884–888) proved unworkable: the Viking onslaught was then at its worst, and the king proved incapable of managing defenses, which fell naturally to the regional magnates. Among these was Eudes, son of that Robert the Strong to whom counties in the lower Loire valley had been delegated in 866. Eudes's resourceful defense of Paris against the Vikings in 885 contrasted starkly with Charles the Fat's failures, and in 887 the west Frankish magnates deposed Charles and later elected Eudes king. In so doing they bypassed an underage grandson of Charles the Bald, also named Charles, who was crowned at Reims in 893 with the support of the archbishop there. Although gaining undisputed title to the crown upon Eudes's death in 898, Charles the Simple (as he was called) was unable to recover the undivided loyalty of his great men. Having ceded Normandy to a Viking band in 911 and having sought to reward the service of lesser men, he lost the crown in 922 to Eudes's brother Robert, who was killed in battle against Charles in 923. Thereupon Robert's son-in-law Raoul of Burgundy was elected king and Charles the Simple was imprisoned, to die in captivity in 929. Yet, when Raoul died in 936, the Robertian candidate for the crown, Robert's son Hugh the Great, stood aside for another Carolingian restoration in the person of Louis IV, son of Charles the Simple and called d'Outremer ("from Overseas") because he had been nurtured in England since his father's deposition. Louis IV acted energetically to revive the prestige of his dynasty, leaving the crown undisputed at his death in 954 to his son Lothaire (954–986). But Lothaire's dynastic resources were too seriously impaired to command the full allegiance of the magnates. When his son Louis V (986–987) died young, the magnates reasserted themselves to elect Hugh Capet king. This time, despite the survival of a Carolingian claimant, Charles of Lorraine, the dynastic breach was permanent.

Crisis of power

The election of 987 coincided with a more general crisis of power. The pillaging of Vikings gave way to that of castellans and knights; the inability of kings (of whatever family) to secure professions of fidelity and service from the mass of people in lands extending beyond a few counties shows how notions of personal loyalty and lordship were replacing that of public order. Just as castellans were freeing themselves from subordination to counts, so the monks claimed exemption from the supervision of bishops: in a famous case the bishop of Orléans was opposed by the learned Abbo of Fleury (d. 1004). There was a new insistence on the virtue of fidelity—and on the sin of betrayal.

Hugh Capet (987–996) and his son Robert (996–1031) struggled vainly to maintain the Carolingian solidarity of associated counts, bishops, and abbots; after about 1025 Robert and his successors were hardly more than crowned lords, and their protectorate was valued by few but the lesser barons and churches of the Île-de-France. Neither Henry I (1031–60) nor Philip I (1060–1108) could match the success (such as it was) of their rivals in Normandy and Flanders in subordinating castles and vassals to their purposes.

Yet even these relatively weak kings clung to their pretensions. They claimed rights in bishops' churches and monasteries far outside their immediate domain, which was concentrated around Paris, Orléans, Compiègne, Soissons, and Beauvais. Henry I married a Russian princess, whose son was given the exotic name of Philip; and the choice of Louis, a Carolingian name, for Philip's son was even more obviously programmatic. Louis IV (1108–37) spent his reign reducing the robber barons of the Île-de-France to submission, thereby restoring respect for the king's justice; he worked cautiously to promote the royal suzerainty over princely domains. It was a sign of newly achieved prestige that he secured the heiress Eleanor of Aquitaine as a bride for his son Louis VII (1137–80). But Louis VI was less successful in border wars with Henry I of Normandy; these conflicts became more dangerous when, upon the failure of her first marriage, Eleanor married Henry of Anjou, who came thereby to control lands in western France of much greater extent than the Capetian domains. Louis VII proved nonetheless a steady defender of his realm. He never relinquished his claim to lordship over the Angevin lands, and he allowed lesser men of his entourage the freedom to develop a more efficient control of his patrimonial estate. Not least, he fathered—belatedly, by Queen Adele of Champagne, his third wife, amid transports of relieved joy—the son who was to carry on the dynasty's work.

The early Capetian kings thus achieved the power of a great principality, such as Normandy or Barcelona, while harbouring the potential to reestablish a fully royal authority over the greater realm once ruled by Charles the Bald. The princes were their allies or their rivals; they sometimes did homage and swore fealty to the king, but they were reluctant to admit that their hard-won patrimonies were fiefs held of the crown. Royal lordship over peasants, townspeople, and church lands was for many generations a more important component of the king's power in France. It was exercised personally, not bureaucratically. The king's entourage, like those of the princes, replicated the old Frankish structure of domestic service. The seneschal saw to general management and provisioning, a function (like that of the mayors of the palace) with the potential to expand. The butler, constable, and chamberlain were also laymen, the chancellor normally a cleric. The lay officers were not agents in the modern sense; their functions (and incomes) were endowed rewards or fiefs, for which they seldom accounted and which they tended to claim as by hereditary right. In a notorious case, Stephen of Garland tried to claim the seneschalsy as his property and for a time even held three offices at once; but this abuse was soon remedied and taught caution to Louis VI and his successors. The chancellor drafted the king's decrees and privileges with increasing care and regularity. He or the chamberlain kept lists of fiscal tenants and their obligations on the lord-king's estates and in towns for use in verifying the service of provosts who collected the rents and profits of justice. But this service was hardly less exploitative than that of the household officers; the royal domain lagged behind the princely ones of Flanders and Normandy in the imposition of accountability on its servants. The abbot Suger of Saint-Denis (d. 1151), once a provost on his monastery's domains, was instrumental in furthering administrative conceptions of power in the court of Louis VII.

France, 1180 to *c.* 1490

FRANCE FROM 1180 TO 1328

The kings and the royal government. The French monarchy was greatly strengthened by Louis VII's successor, Philip II Augustus (ruled 1180–1223), who could claim descent from Charlemagne through his mother. Philip proved to be the ablest Capetian yet to reign. He was practical and clear-sighted in his political objectives; the extension of territorial power and the improvement of mechanisms with which to govern an expanded realm were his consistent policies. Perhaps it was not accidental that royal documents began to refer to the king of France (*rex Franciae*) instead of using the customary formula king of the Franks (*rex Francorum*) within a year or two of Philip's accession.

Territorial expansion

Philip Augustus. Philip's outstanding achievement was to wrest control from the Plantagenets of most of the domains they held in France. Intervening in struggles between Henry II of England and his sons, Philip won preliminary concessions in 1187 and 1189. He acquired strategic lands on the Norman borders following wars with Henry's sons, King Richard and King John (1196 and 1200). And when, in 1202, John failed to answer a summons to the vassalic court of his lord, Philip Augustus confiscated his fiefs. Normandy, invaded in 1204, submitted to the Capetian in 1208. Maine, Anjou, and Touraine fell rapidly (1204–06), leaving only Aquitaine and a few peripheral domains in the contested possession of England. By the Truce of Chinon (Sept. 18, 1214), John recognized the conquests of Philip Augustus and renounced the suzerainty of Brittany, although the complete submission of Poitou and Saintonge was to take another generation.

Philip's other acquisitions of territory, if less spectacular, were no less important for consolidating the realm. In the north he pressed the royal authority to the border of Flanders. Artois, which came under his control as a dowry with his first wife, was fully secured in 1212. Vermandois and Valois (1213) and the counties of Beaumont-sur-Oise and Clermont-en-Beauvais were annexed during his last years. On the southern limits of the Île-de-France Philip rounded out prior possessions in Gâtinais and Berry. Much of Auvergne, whose suzerainty had been ceded by Henry II in 1189, passed to royal control in 1214, while in the more distant south Philip extended his influence by gaining lordship over Tournon, Cahors, Gourdon, and Montlaur in Vivarais. As the reign ended, only Brittany, Flanders, Champagne, Burgundy, and Toulouse, among principalities later annexed, lay outside the royal domain.

Because the territorial expansion was accomplished through traditional means—dynastic, feudal, and military—the curial administration was, outwardly, little changed. Household officers such as the butler and the constable continued to function as in the past. But Philip Augustus was even more suspicious of the seneschalship and chancellorship than his father had been; he allowed both offices to fall vacant early in his reign, entrusting their operations to lesser nobles or to clerics of the entourage. Although their activity is obscure, some of these men were beginning to specialize in justice or finance. The curia as such, however, remained undifferentiated; characteristically, the committee of regents, appointed in 1190 to hold three courts yearly while the king was absent on crusade, was expected to function in both justice and administrative review on those occasions. Prelates and nobles of the curia also served as counselors; enlarged councils convened, at the king's summons, on festivals or when major political or military issues were contemplated.

Royal administration

Philip Augustus acted vigorously to improve the efficiency of his lordship. He was, indeed, practically the founder of royal administration in France. His chancery began to keep better records of royal activities. Documents were copied into registers before being sent out, and lists of churches, vassals, and towns were drawn up to inform the king of his military and fiscal rights. These lists replaced others lost on the battlefield of Fréteval·(1194), a disaster that may have hastened the adoption of a new form of fiscal accountancy. One may draw this conclusion because it is unlikely that the Capetians had previously troubled to record the balances of revenues and expenses in the form first revealed by a record of the year 1202. Its central audit was connected with other efforts to improve control of the domains dominated directly by the king. From early in his reign Philip appointed members of his court to hold periodic local sessions, to collect extraordinary revenues, to lead military contingents, and to supervise the provosts. The new officers, called bailiffs (*baillis*), at first had no determined districts in which to serve (they resembled the circuit commissioners of Angevin government, whose office may have been the model for the Capetian institution). From the outset the bailiffs were paid salaries; they were more reliable than the provosts, who, by the later 12th century, generally farmed the revenues. In the newly acquired lands of the west and south Philip and his successors instituted seneschals—functionaries similar to the bailiffs, but with recognized territorial jurisdiction from the start.

Philip Augustus' policy toward his conquered domains was shrewd. He retained the deep-rooted customs and administrative institutions of such flourishing provinces as Anjou and Normandy; indeed, the superior fiscal procedures of Normandy soon exercised perceptible influence on Capetian accounting elsewhere. On the other hand, to secure the loyal operation of provincial institutions, Philip appointed men of his own court, typically natives of the Île-de-France. It was a compromise that was to work well for generations to come.

Philip's relations with his subjects

The character of Philip's rule may likewise be deduced from his relations with the main classes of the population. A devoted son of the church, if not unswervingly faithful, he favoured the higher clergy in many of their interests. He opposed the infidels, heretics, and blasphemers; he supported the bishops of Laon, Beauvais, Sens, and Le Puy (among others) in their disputes with townspeople; and he granted and confirmed charters to monasteries and churches. Yet he was more insistent on his rights over the clergy than his predecessors had been. He required professions of fidelity and military service from bishops and abbots, cited prelates to his court, and sought to limit the jurisdiction of ecclesiastical courts. He supported papal policies or submitted to papal directives only to the extent that these were consistent with his temporal interests. His reserved support of crusades and his notorious rejection of Queen Ingeborg were cases in point (see below).

Toward the lay aristocracy, Philip Augustus acted energetically as suzerain and protector. Indeed, no Capetian was more fully the "feudal monarch." His war with John resulted from a breach of feudal law and was fought with feudal levies. He regarded Flanders and Toulouse as well as Normandy as fiefs held of the crown. As with ecclesiastical vassals, Philip insisted upon the service due from fiefs; he exploited the feudal incidents, notably relief and wardship; and he required his vassals to reserve their fealty for himself alone. He extended his influence by entering into treaties (*pariages*) with minor lords, often distant ones; and, by confirming the acts of nobles in unprecedented numbers, he recovered the force of the royal guarantee.

The policy toward the lesser rural and urban populations was to increase their loyalty and contribution to the crown without significantly reducing their dependence on the king and other lords. Philip offered his protection to exploited villages, and, especially during his early years, he confirmed existing "new towns," extended their privileges to other villages, and otherwise favoured peasant communities. Townsmen, notably those in semiautonomous communes, gained confirmation of their charters; and the king created some new communes. Most of the latter were located in strategic proximity to the northern frontiers of the expanded royal domain; this fact, together with the obligations of service and payment specified in the charters, suggests that military motives were paramount in these foundations. More generally evident in these charters, as in others, was the desire to gain the political fidelity of a prospering class. At Paris Philip Augustus acted as did no other local lord to promote the civic interest: improving sanitation, paving streets, and building a new wall. Parisian burghers financed and administered these projects; they were associated in the fiscal supervision of the realm when the king went on crusade, but they were not favoured with a communal charter.

Appanages

Louis VIII. The reign of Louis VIII (ruled 1223–26) had an importance out of proportion to its brevity. It was he (this frail husband of the formidable Blanche of Castile and father of famous sons) who first brought Languedoc under the crown of France and who inaugurated the appanages—grants of patrimonial land to members of the royal family or royal favourites—thereby creating a familial condominium through which the expanded France of later generations was to be governed. The conquest of Languedoc, following the Albigensian Crusade (against heretics in southern France) that was only tepidly supported by Philip Augustus, was not complete until the 1240s, but the royal seneschalsies of Beaucaire and Carcassonne were already functioning when Louis VIII died. And it was in keeping with that ruler's will of 1225 that the great appanages passed to his younger sons as they came of age—Artois to Robert in 1237; Poitou, Saintonge, and Auvergne to Alphonse in 1241; and Anjou and Maine to Charles in 1246.

Louis IX. The real successor to Philip Augustus, however, was his grandson, Louis IX (ruled 1226–70), in whose reign were fulfilled some of the grand tendencies of prior Capetian history.

Louis IX, who was canonized in 1297, is the best-known Capetian ruler. He impressed all who came in touch with him, and the records of his reign—anecdotal and historical as well as official—leave no doubt that he commanded affection and respect in a combination and to an extent that were unique. He regarded himself as a Christian ruler, duty-bound to lead his people to salvation. He led by example, precept, and correction. He earned a reputation for fairness and wisdom that enabled him to rule as absolutely as he wished; only with the crusade, perhaps, did his judgment falter. His reign was marked by consolidation, maturation, and reform rather than by innovation.

Louis IX's territorial acquisitions

In his early years baronial revolts, supported by Henry III of England, were put down by the regency, headed by the queen mother, with singular firmness and skill. Poitou and Saintonge remained restive largely because of the stubborn machinations of Isabella of Angoulême (King John's widow); it was only in 1243, after a revolt planned to coincide with an uprising in Languedoc, that the feudal adjudication of 1202 was fulfilled in Aquitaine. The revolt of Raymond Trencavel, dispossessed heir to the viscounty of Béziers, halfheartedly supported by Raymond VII of Toulouse, was no more successful; its failure resulted in the vindictive destruction of the petty nobility of Languedoc, and many fiefs thereupon passed to the crown. In 1239 a childless count of Mâcon sold his domains to the king.

Such were the principal territorial acquisitions of Louis IX; the balance of his work, however, was to be affected further by three characteristic events. First, despite his victory of 1243, Louis remained disposed to compromise with Henry III; in the Treaty of Paris (December 1259) Henry regained feudal title to lands and reversionary rights in Guyenne in exchange for renouncing all claims to Normandy, Anjou, Maine, Touraine, and Poitou. Similarly, by the Treaty of Corbeil (May 1258) Louis himself had abandoned ancient claims to Catalonia and Roussillon in exchange for the renunciation of Barcelona's rights in Gévaudan and Rouergue. Meanwhile, upon the death of Raymond VII in 1249, the county of Toulouse had passed to Raymond's son-in-law, Alphonse of Poitiers, who proceeded to govern it as effectively as his appanage lands; and when he and his wife died without issue in 1271, their enormous inheritance reverted to the royal domain.

The ancient household administration died out in the 13th century. Offices such as the chancery and treasury became more specialized and bureaucratic, while the greater advisory personnel formed a fluctuating corps of reliable favourites: bishops, abbots, and minor nobles of the old Capetian homelands. The counselors, meeting in diverse political and ceremonial capacities, continued to assemble with other prelates and barons during festivals or ad hoc. But the fiscal and judicial activities of the court were growing in volume and technicality. Ordinary revenues expanded apace with the royal domains; taxes ceased to be exceptional. Toward 1250, judgments of the curia began to be recorded centrally; and the judicial sessions, now often called *parlements*, derived an ever-expanding jurisdiction from the king's repute.

Meanwhile, a real local administration evolved as the bailiffs and seneschals became well established in territorial circumscriptions. Complaints arose when these men, and more particularly their subordinate officers, abused their powers for personal profit or the king's. Commissions of investigation, first appointed in 1247, provided means for redress; and these investigators continued to function after Louis returned from his first crusade in 1254.

Domestic policies of Louis IX

Although previous rulers had legislated on occasion, Louis IX was the first to express his will regularly in statutory form. A great ordinance for administrative reform in 1254 resulted from the remedial inquiries. In other enactments, characteristically moral and authoritarian, Louis sought to curb private warfare (about 1258) and to promote the use of royal money while limiting that of baronial (1263–65).

Toward the clergy Louis IX manifested a sympathy born of conservatism and exceptional piety, but he was nonetheless a firm master. He opposed efforts to expand clerical jurisdictions. During his later years he supported papal taxes on the clergy for the crusade, although in the 1240s he had joined his clergy in opposing papal preferments and impositions for a war against the emperor Frederick II. The lay nobles found Louis IX a frustrating ruler. Sharing few of their values, he consistently tried to limit their ability to cause disorder. He allowed royal officials to encroach on baronial jurisdiction in many cases, and he welcomed appeals from baronial judgments. On the other hand, he respected such rights as were sanctioned by provincial custom and was less forceful in exploiting feudal relationships than his grandfather had been.

The royal interest in order and justice was especially beneficial to townspeople and peasants, who had most suffered from exploitative agents and private war. Louis IX confirmed municipal charters, but he also taxed the towns heavily. When oligarchical urban governors mismanaged finance to the disadvantage of the lower classes as well as the king, he moved energetically (1259–62) to place the fiscal administration of 35 communes directly under the crown. A crusade of peasants known as the Pastoureaux (1251) was inspired by loyalty to the king, then in trouble in the Holy Land; when its impulse was dissipated in agitation against the propertied classes, the regent had it suppressed.

Later Capetians. Louis IX was succeeded by his son, Philip III (ruled 1270–85); his grandson, Philip IV the Fair (ruled 1285–1314); and three great-grandsons, Louis X (ruled 1314–16), Philip V (ruled 1316–22), and Charles IV (ruled 1322–28). The greatest of these last Capetian reigns was that of Philip IV. Worldly and ambitious, yet pious and intelligent, he was less accommodating than his forebears and more devoted to his power than to his reputation. He brought the monarchy to a degree of coordinated strength it was not again to have in the Middle Ages. But, in so doing, he strained the resources and patience of his subjects. His sons had to give in to the demands of a tired country but did so without abandoning their father's objectives. When Charles IV died without a male heir in 1328, as his brothers had done before him, the royal succession was claimed by a collateral Capetian family.

Further territorial consolidation

The reigns of the later Capetian kings were marked by further territorial consolidation. Marrying his son to the heiress of Champagne and Navarre in 1284, Philip III prepared the way for a reversion no less important than that of Toulouse (1271). Philip the Fair secured the heiress to the county of Burgundy for his son Philip in 1295 and annexed southern Flanders and Lyon in 1312. Smaller acquisitions, cumulatively of great importance, resulted from purchase: the counties of Guînes (1281), Chartres (1286), La Marche and Saintonge (1308); the viscounties of Lomagne and Auvillars (1302) and La Soule (1306); and a number of untitled lordships.

Through treaties, Philip the Fair extended his jurisdiction into the ecclesiastical principalities of Viviers, Cahors, Mende, and Le Puy. With his greatly expanded domain, the king could assert unprecedented authority everywhere in France. Yet it does not appear that territorial policy as such had changed. Appanages were still to be granted and to be recovered by the later Capetians. The monarchs continued to do without Brittany, Burgundy, and many lesser lordships, which did not prevent them from legislating for these lands along with the rest.

Government became more engrossing, specialized, and efficient. Although the royal curia continued to exist as an aggregate of favourites, magnates, prelates, and advisers, its ministerial element—comprising salaried officers serving at the king's pleasure—functioned increasingly in departments. The small council acquired definition from an oath first mentioned in 1269. Parlement, its sessions lengthening under a growing burden of cases, was divided into chambers of pleas, requests, and investigations (1278), and its composition and jurisdiction were regulated. Older provincial tribunals, such as the Norman Exchequer and the Jours of Troyes, became commissions of Parlement. While the direction of finance was left with the council, the Chamber of Accounts, apart from the treasury, was organized to audit accounts. Council and chamber as well as Parlement developed appropriate jurisdiction, and all three bodies kept archives. The chancery, serving all departments, remained in the hands of lesser functionaries until 1315, when Louis X revived the title of honour.

Local administration was marked by the proliferation of officers subordinate to the bailiffs and seneschals. The chief judge (*juge-mage*) assumed the seneschal's judicial functions in the south; receivers of revenues, first appearing in Languedoc, were instituted in the bailiwicks at the end of the 13th century. Commissions of investigation continued to traverse the provinces under the later Capetians, but all too often they now functioned as fiscal agents rather than as reformers.

Royal authority of Philip the Fair

Many of the officers who served Philip the Fair were laymen, and many were lawyers. Impressed with the power they wielded, they promoted loyalty to the crown and a conception of the royal authority approaching that of sovereignty. Without claiming absolute power for the king, they thought in terms of his "superiority" over all men within national boundaries now (for the first time) strictly determined; and they did not hesitate to argue from Roman law that, when the "state of the kingdom" was endangered, the monarch had an overriding right to the aid of all his subjects in its defense. While this doctrine, in a notorious case, was made a justification for imposing on the clergy, the later Capetians did not lose the religious mystique they had inherited from their predecessors' efforts in Christian causes. Even as political loyalties were being engrossed by the lay state, the "religion of monarchy" derived impetus from the fervent utterance of those who saw in Philip the Fair a type of Christ or the ruler of a chosen and favoured people.

It was in the requirements of war and finance that the claims of the monarchy found most concrete expression. In the 1270s, for his campaigns in the south, Philip III requested military aid from men theretofore exempt from such service. Philip the Fair, renewing these demands for his wars in Gascony and Flanders, went so far as to claim the military obligation of all free men as the basis for taxing personal property. The most persistent and lucrative taxation after 1285 was that imposed on the clergy, generally in the form of tenths and annates; sales taxes, customs, tallages on Jews and foreign businessmen, and forced loans likewise supplemented older revenues of the domain to support increased administrative expenses as well as costs of war. The most unpopular fiscal expedients were the revaluations of coinage after 1295, by which the king several times increased the profits of his mints to the confusion of merchants and bankers. The imbalance between ordinary resources and the needs of an expanding government became chronic at the end of the 13th century. Yet, in spite of the statist arguments of their lawyers, none of the later Capetians was moved to regard taxation as an established and justified requirement of a national government.

Philip's use of councils and assemblies

Such restraint is one reason why, with momentary lapses, the strongest of the later Capetians was not regarded as an arbitrary ruler. Philip the Fair revered St. Louis (Louis IX) as much as did his people; like Louis he took counsel from a relatively few unrepresentative persons. But, when Philip's own policies broke with the past, he resorted to great councils and assemblies, not so much to commit the nation as to justify his course. Whether a tax was sanctioned by custom or not, even if approved by assembled magnates or townsmen, he had it negotiated—reexplained and collected—in the provinces and localities. Large central assemblies in 1302, 1303, 1308, and 1312 met to enable the king and his ministers to arouse political support for his measures against the pope or the Knights Templars (see below).

Among these assemblies were the earliest national assemblies that included representatives of towns and villages, a fact that has caused historians to classify them with the Estates-General. Under Philip the Fair and his sons, however, these convocations were not yet understood to be representative of the estates of society; only when Philip V began to summon northern and southern men separately to deliberate on fiscal matters were the estates (which made up the Estates-General) in any way anticipated. Almost simultaneously the provincial Estates were foreshadowed in the petitions of magnates and towns in several regions for relief from administrative violations of traditional privilege; but the resulting charters of 1314–15 were poorly coordinated and reactionary, and they did little to limit royal power, although the fiscal rights later claimed by the Estates of Normandy could be traced to the Norman Charter of 1315.

If the policies of Philip the Fair evoked the complaint of all classes of people, it was because he had favoured none in particular; in fact, except in war and finance, the later Capetians may be said to have maintained a traditional politics toward both the nobles and towns. With the church, however, it was otherwise. Philip the Fair's insistence on taxing the clergy for defense led immediately to his conflict with Pope Boniface VIII. The latter, in the bull *Clericis laicos* (1296), issued on the protest of both French and English prelates, forbade the payment of taxes by clergymen to lay rulers without papal consent; but Philip's anger and his political arguments divided the clergy, and the pope soon found it necessary to abandon his position.

The quarrel was renewed in 1301, when the king and the magnates accused the bishop of Pamiers of treason and heresy. Boniface not only revoked the concessions of 1297 but rebuked Philip for seizing clerical property and debasing the coinage, among other things, and he summoned French prelates to Rome to proceed with a reform of the kingdom. Once again the clergy was split; many bishops and abbots attended an assembly at Paris in 1302 where they joined men of the other estates in addressing a remonstrance to the pope. A year later the king adopted rougher tactics: in June 1303 many prelates acquiesced in a scheme to try the pope before a general council, and in September the king's envoy Guillaume de Nogaret and his accomplices seized Boniface at Anagni. When the aged pope died a month later, his audacious policy collapsed entirely. The Gascon pope Clement V (reigned 1305–14) moved the Holy See to Avignon, and a mass of his compatriots were appointed cardinals.

Destruction of the Templars

With this pliant pontiff, the way was cleared for the strangest act of violence of the reign of Philip the Fair—the destruction of the Knights Templars. Founded in the 12th century in support of the Crusades, the French Templars by about 1300 were aged men whose privileges seemed poorly justified after the fall of the Holy Land. But Philip's case was pressed relentlessly beyond the evidence brought forth; the king had to resort to propaganda in a vast assembly held at Tours in 1308, and it was only in 1312 that the pope, his scruples overcome by expediency, dissolved the order. The Templars' possessions were given to the Hospitalers, and their last dignitaries were imprisoned or executed.

Foreign relations. France assumed a more active role in the politics of Christian Europe from the end of the 12th century. Philip Augustus led French contingents on the most fully international of the great Crusades (1190–91), although, having once demonstrated his energy in that work of piety, he could not afterward be persuaded to renew his vow. He preferred, through dynastic schemes and opportunism, to exploit his rivalry with the Plantagenets. His ambition seems to have embraced England as early as 1193, when he married Ingeborg, whose brother, the king of Denmark, had an old claim to the throne of England. When Philip, for private reasons, repudiated Ingeborg the day after the wedding and sought to have the marriage annulled, she and her brother appealed to the pope; her case, punctuated by reconciliations with Philip dictated more by policy than by sentiment, dragged on through the pontificate of Innocent III.

Meanwhile, in 1200, Philip's son Louis married Blanche of Castile, granddaughter of Henry II, through whom another claim to England was heralded. Louis's career as prince was marked by aggressive designs against King John. Innocent III was prepared to recognize Louis as king of England in 1213; and the policy was dropped only after Louis's abortive invasion of 1216–17.

It was in the play of rival coalitions that Philip Augustus had his greatest diplomatic anxiety and success. Philip countered John's alliance with Otto of Brunswick, his nephew and claimant to the empire, by supporting a second claimant, Philip of Swabia. When Otto became emperor in 1209 and the counts of Flanders and Boulogne were alienated from their Capetian suzerain, Philip found himself seriously threatened in his northern heartlands. John's desire to avenge the loss of his French fiefs finally prompted him to act in 1214; he himself led a force from the west, and his major allies marched on Paris from the north. Philip Augustus met the allied forces at Bouvines in July 1214 and won a decisive victory. As John retreated and his coalition collapsed, there could be no doubt that Capetian France had achieved hegemony in Christian Europe.

Diplomacy of Louis IX

Louis IX acted astutely, though in ways unlike his grandfather's, to preserve the prestige of France. His treaties with Aragon and England, designed to extend and secure his domains, resulted from a cordiality better appreciated abroad than by the royal counselors. From Navarre and Lorraine as well as from within the realm were brought disputes for his judgment; and in the Mise of Amiens (1264) Louis responded to the appeal of Henry III and the English barons to pronounce on the validity of the Provisions of Oxford (a written agreement between the king and magnates in England to reform the state of the realm). But the more absorbing issues of Louis's diplomacy lay in the east. He resisted papal urgings to take sides against Frederick II, believing in the equal legitimacy of empire and papacy. On the other hand, he allowed his brother Charles of Anjou to accept the crown of Sicily from the pope; for this enterprise, as for his own crusades, he allowed the papacy to tax the French clergy. His paramount foreign interest was to recover the Holy Places for Christ, a traditional ambition characteristically associated in his mind with the hope of converting the infidel: the Mongols or the emir of Tunis.

Louis IX first took the cross in 1244, upon learning that a Turkish-Egyptian coalition had driven the Christians of the Levant back to precarious coastal positions. His expedition, which was well planned and well financed, set out in 1248, only to founder in the plague-ridden floodwaters of Egypt a year and a half later. Louis himself was captured; upon his release, he spent four years in Syria in support of the Christian cause. He renewed his crusader's vow in 1267, in circumstances clouded by Angevin-Sicilian politics. Persuaded in secret by Charles, whose inordinate Mediterranean ambitions had little in common with the traditional crusade, the new expedition was diverted to Tunis. It broke up there with the king's death in 1270.

The prestige of France in Christendom lost little from these failures of Louis IX. Nor was it generally foreseen that Aquitaine and Sicily would become battlegrounds in the future.The apparent strength of his father's diplomacy deterred Philip III from changing it, even though circumstances had changed. When in 1282 the misrule of Charles of Anjou caused the Sicilians to revolt in favour of Peter III of Aragon, leading to the War of the Sicilian Vespers, a test of the Angevin policy could no longer be deferred. Charles's friend Pope Martin IV (reigned 1281–85) excommunicated the king of Aragon and offered the vacant throne to Philip for one of his sons. Because at this juncture the crown of Navarre was destined for Philip's son and successor, Philip the Fair, the whole Spanish March seemed ripe for recovery by the French. Yet the crusade against Aragon, blatantly political and impractical, came to a catastrophic end: the king himself died as his battered forces staggered out of Catalonia (October 1285). Charles of Anjou and Martin IV also died in 1285. Understandably, Philip the Fair, who had foreseen the folly of the ill-conceived attack on Aragon, no longer permitted Mediterranean concerns to dominate foreign policy. The issue over Sicily dragged on, but minor Capetian interests in the Pyrenees and in Castile were allowed to lapse.

Extension of French influence to the north and east

The extension of French influence and domain toward the north and east was the result of resourceful diplomacy at the expense of the empire. Philip's interest in that direction was emphasized when his sister married the son of Albert I of Germany and when he proposed first his brother and later his son as candidates for the imperial title. But it was against the English holdings in France that Philip exercised his most aggressive and portentous diplomacy.

Questions over spheres of administrative rights in Aquitaine had been creating tensions for many years. By the Treaty of Amiens (1279) the Agenais, whose status had been left in doubt when Alphonse of Poitiers died, passed to Edward I of England, who also had unsettled claims in Quercy. Serious conflict was precipitated in 1293, when clashes between French and English seamen caused Philip the Fair to summon his vassal to Parlement. When Gascon castles occupied by the French as part of the settlement were not returned to the English on schedule, Edward renounced his homage and prepared to fight for Aquitaine. The war that ensued (1294–1303) went in favour of Philip the Fair, whose armies thrust deep into Gascony. Edward retaliated by allying with Flanders and other northern princes. His dangerous campaign, concerted with the count of Flanders in 1297, met defeat from a French force led by Robert of Artois, and during a truce from 1297 to 1303 the rival monarchs reestablished the status quo ante. Edward married Philip's sister, and a marriage was projected between Prince Edward and Philip's daughter.

A consequence of this first war was to be the chronic insubordination of Flanders. After the count's surrender

The growth of the French royal domain, 1180–1328.

and imprisonment, it was left to the Flemish burghers to revolt against the French garrisons, and the French knights suffered a terrible defeat at Courtrai in July 1302. Thereafter the tide turned. But it was only in 1305 that a settlement satisfactory to the king could be reached; even then it proved impossible to win full ratification from the Flemish townsmen, whose resistance remained an invariable factor in the latent hostility between France and England.

In 1320 Philip the Fair's son, Philip V, obtained Edward II's personal homage, but friction was increasing in Gascony again. When Edward refused to do homage to Philip V's brother and successor, Charles IV, an old issue relating to French rights in Saint-Sardos (in Agenais) flamed into a war that once again went in favour of the French. By the Treaty of Paris (March 1327) France recovered Agenais and Bazadais and imposed a heavy indemnity on England, but a number of issues were left unresolved. Meanwhile, having married the emperor Henry VII's daughter, Charles was tempted to negotiate for the vacant imperial title in 1324; but nothing came of this. The last Capetians, although troubled at home, retained their international standing among neighbouring states, which were no less troubled.

Population growth

Economy, society, and culture in the 13th century. The primary social fact of this period is the continued growth of population. All indicators suggest growth—*e.g.,* expansion of old towns, founding of new villages, the rising price of land—but no exact measurements are possible. A register of hearths dating from 1328 has been estimated variously to point to a total population of 15 million to 22 million; the total was probably slightly reduced after a crest toward the end of the 13th century. By the 1280s large portions of France had enjoyed many years of relative security and prosperity, even though private warfare had not disappeared, despite royal prohibitions. Brigandage seems actually to have worsened in the south around 1200. The ravages and massacres of the Albigensian Crusade made Languedoc an insecure frontier for still another generation, though it does not appear that the Inquisition seriously disrupted urban or rural prosperity after about 1230.

The broad tendencies of social change were in keeping with political and institutional progress. The conjugal family became better recognized: Roman and especially canon law favoured its authority over the wider solidarities of clan or kin (extended family); rulers made the hearth a basis of fiscal responsibility. While mercantile practice discouraged customary restrictions on transactions, the right of repurchase by some member of the extended family held out in most areas of France. Meanwhile, a new territorial solidarity of potentially great significance was developing: that of the legal estate or class. This development was associated with the growth of towns and fostered by the consolidation of provincial custom and the fiscal impositions of count, bishop, or king. Already in 12th-century Flanders, knights (or towns) of the countryside were acting politically; the convocation of men from these incipient estates of society occurred elsewhere in France as well and more often during the 13th century. Social mobility remained considerable in spite of tendencies to restrict the ranks of urban patricians or rural nobles.

Urban prosperity. Town life continued to flourish. A few places, favoured by political and ecclesiastical as well as by economic circumstances, grew far larger than the rest. Paris could probably count more than 100,000 inhabitants by the late 13th century, possibly many more than that; some great provincial centres—*e.g.,* Toulouse, Bordeaux, Arras, Rouen—may have surpassed 25,000, but most of the older cities grew more modestly. Jewish communities, which existed almost everywhere, were especially important in the towns of Champagne and Languedoc. Immigration from the countryside probably increased as peasants sought better opportunities and independence, yet the towns remained somewhat indistinct in appearance and activity from their rural surroundings. Many urban properties had agrarian attachments, often within the walls; Paris itself was, to a surprising extent, an aggregation of expanded villages. Nevertheless, the progress of commerce, together with an important ancillary development of industry, chiefly accounts for urban prosperity in the 13th century.

Commerce and industry

The trades not only grew in volume but also became more diversified and specialized. New markets, often regional ones, arose to supplement the older centres that had developed on the basis of the long-distance exchange of relatively high-priced imperishables. Regional markets featured such agrarian staples as grains and wines as well as animals, cloth, weapons, and tools, and they facilitated the currency of foreign produce, such as glassware or spices. An increasing reliance on coinage or on monetary values may be connected with these provincial trades; sensitivity to the intrinsic values of the many French coinages was increasing everywhere toward 1200, even in the hinterlands away from main trading routes. In the late 13th century the need for money in denominations larger than the age-old penny (denarius)—primarily for use in the great commercial centres—caused Louis IX to issue the *gros tournois* (worth 12 pennies) and the gold coin (which, however, had little importance before the 14th century). A gradual long-term inflation tended to favour commercial activity.

The towns of northern France, notably in Artois, Burgundy, the Île-de-France, and especially in Champagne, prospered not only from regional exchange but also from the great overland trades connecting Normandy, England, the Baltic, and the Low Countries with the cities of Italy. The fairs of Champagne, becoming the leading entrepôt of European merchants, reached their apogee in the 13th century. Favoured by the count's privilege, the traders operated at Lagny or at Bar or—in greater numbers—at Provins and at the "warm fair" of Troyes in June; the "cold fair" of Troyes ended the yearly cycle in October. The fairs were designated as occasions for payment and repayment, contributing significantly to the progress of banking and business accounting.

Enlarged and more diversified demand encouraged urban growth and prosperity. Townsmen were eating better: in the north, at least, the per capita consumption of meat, butter, and cheese, as well as of spices, seems to have increased in the 13th century. As for wine, not only was more being drunk but the taste for *vins de qualité* became more acute, and the great regional vintages, notably that of Gascony, were established. Townspeople furnished their houses more amply than in the past (lamps, wooden chests, and draperies came into common use), and they produced more articles themselves.

The progress of industry, in fact, was a remarkable feature of the 13th century. Crafts in metal, wood, leather, and glass expanded in such large towns as Paris; clothwork—weaving, dyeing, fulling—prospered in regional centres such as Toulouse, with specialities in fine cloths concentrated in Artois and Flanders. In most places, however, the crafts remained in the shadow of commercial enterprise, in which the greater fortunes continued to be made. Artisanal associations proliferated everywhere; often termed brotherhood (*confratria, confraternitas*), they fostered new urban and suburban solidarities for charitable and ceremonial purposes as well as for the promotion of economic interests.

Urban society

Urban society became more competitive and more stratified. At Lyon, Bordeaux, and elsewhere, some fortunes were well enough established, usually from commerce, to enable their possessors to live as landlords, build stone houses, buy rural property, and aspire to titles of nobility. This patriciate, despite occasional setbacks at the hands of "new men," dominated municipal governments, acting as mayors and magistrates (*échevins*) in the north or as consuls in the south. While not altogether self-serving—they supported civic projects such as the building or decorating of churches—they were disinclined to share power or fiscal responsibility. Below them, often as their tenants or debtors, were small entrepreneurs, middlemen in trade (or between local industry and regional trade), master craftsmen, and bankers; and below all—and increasingly restive—was a swelling class of impoverished artisans, servants, vagabonds, and beggars.

Rural life. Rural life changed more gradually. The expanding markets favoured well-endowed or efficient lords or peasants who could produce a surplus of goods for sale. Such conditions were less common in the south than in the north, although they could be found in most wine-producing areas. But, while rising prices benefited producers, they contributed to certain difficulties in the countryside. Fixed revenues in coin proved an unsatisfactory alternative to payments in kind, which landlords specified when new land was put under cultivation. Moreover, needs and tastes became more expensive and tended to exceed aristocratic resources; lavish generosity continued to be an admired and practiced virtue, and costly crusades—occasionally lapsing into speculative adventures—continued to be launched. Larger lordships began to employ salaried estate managers, while in the south the division of landed fortunes among numerous heirs resulted in a multiplied and impoverished petty nobility. Many rural landlords fell into debt in the 13th century. And, as wealth and nobility became less correlated, some nobles, especially those hard pressed, sought to close ranks against the intrusion of new men or creditors. They insisted on noble birth as a condition for knighthood, while reserving the designation of "squire" (or *donzel,* in the south) for those of noble birth awaiting or postponing the expensive dubbing (*adoubement*). At the upper extreme a noble elite, the barons, achieved recognition in administration and law.

Peasant stratification

Peasant societies also became stratified. Men unable to set aside a surplus against times of famine and those who had to borrow or rent their tools or teams found it difficult to avoid dependence on other men. In some areas serfdom was renewed, or confirmed, as jurists interpreted the more stringent types of peasant obligation in the light of the revived Roman law of slavery. But here again economic and legal status did not necessarily coincide. Rich peasants who employed other men to drive their teams could be found in any village; such people as the mayor, the lord's provost, and the peasant creditor established themselves as a rural elite, whose resources insured them against calamity and opened up diverse opportunities in prospering regional economies. Where enfranchisement occurred, the lord usually received a good payment; even when servility persisted, there was a tendency to commute the arbitrary tallage into fixed common sums. New villages continued to be established, especially in the south, where many existent communities of peasants also received charters of elementary liberties—typically including the commuted tallage—in the 13th and early 14th centuries. In many cases, notably in Gascony, security, or defense, seems to have been the chief motive behind these foundations.

These conditions notwithstanding, the manor, or *seigneurie,* resisted fragmentation. The favourable market for grain and the psychological attachment of lords to their fathers' possessions preserved demesne land as the chief source of seigneurial income through the 13th century. Nor were labour services given up, although the discrepancy increased between work owed and work needed. Accordingly, lords resorted to paid seasonal labour, so that the margin between profit and loss became a more critical calculation than in the past. A new alternative was to lease the demesne to paid managers or sharecroppers, but this practice spread more slowly in France than in neighbouring countries. Whether lords had demesnes and servile tenants or not, the association between landlordship and power remained close. Tenancies or properties smaller than the old *mansus* appeared everywhere, but especially in the north, where horsepower and three-field crop rotations were making possible a more productive agriculture. The burgeoning viticultures of Burgundy and Gascony proved incompatible with traditional demesne lordship and encouraged sharecropping and peasant initiative. Innovation was less common in the uplands of the centre and south, where the manse tended to retain its identity and fiscal utility.

Religion. Whether in countryside or town, the layperson's touch with Christ became more personal and more direct. The crusade was kept alive in France by the widely shared conviction of Jewish guilt and Muslim (and Byzantine) schism. The 13th was the last medieval century in which French Jews could live securely with their Christian neighbours, but their position became progressively more difficult. The regular clergy, however, could no longer be relied upon to set standards of piety and penitence; their observance was either too relaxed or too severe to suit the new conditions. The tendency of the canonical movement of the later 12th century, moreover, had been to accentuate the distinctiveness of the secular priesthood in charge of administering to the laity and the power of holy orders. The Cistercian order, even though it continued to expand, was incapable of sustaining its ascetic impulse completely; its houses, as well as those of the older Benedictines, found their prestige and solvency alike in decline. Nor was the higher secular clergy much better situated to fulfill pastoral obligations. The bishop was by now remote from his flock, acting usually as diocesan supervisor, judge, or lord; his subordinates—the archdeacon and cathedral canons—likewise functioned primarily as administrators. Archbishops were required by the Fourth Lateran Council (1215) to hold annual synods of provincial clergy, a ruling that—although imperfectly observed—probably contributed to some strengthening of discipline.

The clergy

The critical reform was that of the parish ministry. When emphatic measures to improve the education and supervision of priests were adopted in the Fourth Lateran Council, it was already too late in France. For more than a generation, anticlericalism and doctrinal heresy had been spreading, especially in the towns and villages of the east and south. There was a suspicion that sinning priests could not be trusted to mediate God's grace effectively, and the virtue of poverty as an antidote to the worldly cupidity of a prospering society was attractive to many. The merchant Valdes (Peter Waldo), giving up his property and family (1175–76?), took it upon himself to preach in the vernacular to his fellow townsfolk of Lyon. His followers—the "Poor Men"—going sometimes so far as to administer sacraments, contrary to the canons, failed to win papal recognition. Nevertheless, the Waldensian mission, grimly tolerated by the authorities, spread to southern towns, and Valdes himself became active in the campaign against the Cathar sects of southern France. Flourishing in the hill towns and villages between Toulouse and Béziers, the Cathars held alarmingly unorthodox religious beliefs; they rejected the church as the Devil's work, organizing their own ministry.

For this challenge, the secular clergy of Languedoc was no match. To establish an effective counterministry of learned and respectable men, the pope deputed Cistercians to Languedoc; they were soon succeeded by St. Dominic of Calaruega, who spent a decade as mendicant preacher in Languedoc. In 1217, his order of preachers recognized by the bishop of Toulouse and confirmed by the pope, Dominic set out with his fellow friars to work in the wider world "by word and example."

Crusade of Innocent III in Languedoc

Meanwhile, the murder of the legate Pierre de Castelnau (1208) had stirred Innocent III to promote a crusade against the heretics of Languedoc. Led by Simon de Montfort, northern barons attacked towns in the viscounty of Béziers and later in the county of Toulouse with singular fury. Despite massacres and apostasy, the failure of the enterprise as a holy war was underscored by the establishment of a papal inquisition (1233), which stiffened and institutionalized the Dominican measures of dissuasion. The procedure, which became known in many parts of France, was usually entrusted to Dominicans; it relied on the active pursuit of suspects, secret testimony, and—in case of conviction and obstinacy—delivery of the heretic to the "secular arm" for capital punishment. Taking the war and the Inquisition together, it can be said that French heresy was largely destroyed by the end of the Capetian period.

The Franciscans as well as the Dominicans had a spectacular success. Highly organized, with provincial and international administrative institutions, both orders had houses in Paris by 1220, and their members were soon working everywhere in France. Becoming preachers and confessors, they also secured chaplaincies, inspectorships, and professorships as their initiatives in piety, probity, and learning were recognized. Conflict with the secular priesthood naturally resulted; the seculars attempted unsuccessfully to exclude the mendicants from the ministry of sacraments and inveighed against conventual endowments that seemed to contradict the friars' professions of poverty. New religious orders were soon established. The friars stimulated a more active piety among lay people, favouring charitable works and foundations, private devotions, and penitential reading.

Culture and learning. Literacy and elementary learning became more widespread. The courtly tastes of the 12th century, while not obliterated, were overtaken by a more flexible and ironic sensibility evident in vernacular ballads, fables, satires, and moralizing literature, most popular in the northern towns. The burgher or knight began to take a keen interest in the tangible world about him. The taste for clarity, proportion, and articulation, coming to mature expression in the Gothic of Amiens, Paris (Notre-Dame), and Reims, achieved dazzling finesse in the church known as the Sainte-Chapelle, built at Paris by Louis IX in 1245–48 to house the Crown of Thorns. And the taste for order is illustrated by the reorganization of masters, students, and studies as *studia generalia* (or universities); Montpellier became a leading centre of medical learning; Orléans and Toulouse, the latter founded in 1229 to prepare clerks to combat heresy, were noted for law. Paris remained preeminent among the early universities. Its famous schools became associated as the faculties of arts, canon law, medicine, and theology, gaining jurisdictional independence under papal protection by 1231.

During the same years, philosophical doctrines in conflict with Christian orthodoxy began to trouble the theologians, as translations of the metaphysical and scientific works of Aristotle and his commentators reached Paris. For a time the teaching of Aristotle was prohibited there; but by mid-century, when some of the "artists" who had been most attracted to the new philosophy were advancing to theological degrees, efforts were made to incorporate Aristotelian learning in enlarged summaries of Christian knowledge. The *Summa theologica* (1266–72) by the Italian Thomas Aquinas was the greatest synthesis of this type. Its serene power breathes no hint of the controversies in which its author was involved. St. Thomas had taken his theological degree, together with St. Bonaventure, in 1257, when the secular masters were bitterly disputing the friars' privileges within the university. In the end the Dominicans and Franciscans each retained a chair on condition of submitting to university regulations. Thomas' work, however, came under suspicion. A reaction set in against the arts faculty's increasing disposition to take a naturalistic view of all reality. The bishop's condemnations of "error" in 1270 and 1277 were so sweeping as to render even Thomas suspect.

The bishop's condemnations of "error"

Thomas' audacious brand of synthesis was to have no immediate imitators. Nevertheless, the social consequences of his newly organized learning were profound; it created new estates of professional men—lawyers, notaries, trained clerks, physicians, many of them laymen—whose rational and legalist outlook became firmly rooted in French culture.

The dogmatic condemnations of the 1270s were symptomatic. Prosperity and confidence were shaken in many ways in the late 13th century. The papacy, hitherto a support for progressive causes, found itself discredited after its fiasco in the crusade against Aragon; while the removal of the papal court to Avignon in the time of Clement V created a new centre of patronage for arts and letters, it did little to arrest the waning prestige of the church. The burdens of renewed warfare increased social tensions in the towns and depressed civic enterprise; the Jews had their assets confiscated before being expelled in 1306, and the Lombard bankers suffered like treatment in 1311. Economic indicators—while few and difficult to interpret—are generally held to suggest retardation, at least in many parts of France. The business of the fairs of Champagne was falling off by 1300, if not before, while records of Normandy reveal declining agrarian revenues in the half century after 1260. Some regions were "saturated" with people: their existent economic technology could no longer sustain growth. Probably the population was already leveling off, if not yet decreasing, when, from 1315 to 1317, crop failures and famine caused serious disruption and in some places a reversion to subsistence farming.

THE PERIOD OF THE HUNDRED YEARS' WAR

The kings and the war, 1328–1429. At the accession of the house of Valois in 1328, France was the most powerful kingdom in Europe. Its ruler could muster larger armies than his rivals elsewhere; he could tap enormous fiscal resources, including taxes authorized by sympathetic popes of French extraction; there remained only four great fiefs—the duchies of Aquitaine, Brittany, and Burgundy, and the county of Flanders—outside the direct royal domain; and the king's courts continued to press a jurisdictional supremacy that was felt everywhere in the realm. It did not follow, however, that France's superior armies would fight better than its foes or that its resources would not sometimes be dissipated or withheld. France remained a collection of traditional provinces the peoples of which believed that a king should "live off his own," while military success continued to depend on the personal leadership of dynastic rulers whose qualifications as strategists had been less refined by experience and institutional progress than their judicial or administrative competence. The history of France in the 14th century is dominated by efforts of its kings to maintain their suzerainty over the Plantagenets in Aquitaine, efforts that, despite French advantages, were long frustrated.

Philip VI. Philip VI of Valois (ruled 1328–50), grandson of Philip III, was of mature age when he became regent of France in 1328. Upon the birth of a daughter to the widow of his cousin Charles IV, the familiar issue of the succession was posed anew. It was the regent's experience, together with the circumstance that Edward III of England, grandson of Philip the Fair, was under the influence of his disreputable mother, Isabella of France, that probably disposed the council at Vincennes to recognize Philip as king (April 1328).

Philip VI and Edward III of England

Philip's reign began well. Within months he crushed a revolt of the Flemish cloth towns (Cassel, August 1328), thereby recovering the effective suzerainty over Flanders that had eluded his predecessors for a generation. And in 1329 he obtained Edward III's personal homage for the duchy of Aquitaine, an act that not only secured Philip's leadership but also nullified Edward's claim to the crown of France.

This initial success was soon undone. Jurisdictional questions in Gascony remained unsettled. In 1336 Philip VI appeared to be preparing massive support for David Bruce, the Scottish king at war with Edward; and in 1337, alleging defaults in feudal service, Philip ordered the confiscation of Aquitaine. Edward III renounced his homage and again laid claim to the crown of France, and war again was imminent. Despite the new Plantagenet pretensions, the basic causes of conflict were feudal and jurisdictional, not dynastic.

Edward proceeded deliberately and ominously. He fomented discontent among the Flemish clothworkers and then treated with the towns; in so doing he negated the count's fidelity to France; he also purchased the fidelity and service of many princes in the Rhineland and Low Countries. But, to succeed, the English needed a prompt and massive victory on French soil, something Philip VI was able to prevent. Despite Edward's naval triumph off Sluys (1340), which confirmed English control of the seas, his initial advantage was lost as his resources and allies melted away. A truce in September 1340 was extended for several years, during which time Edward intervened in a disputed succession to the duchy of Brittany, while Philip's officials increased their pressure on Gascony. In 1345 English armies counterattacked French posts on the duchy's borders; their success emboldened Edward. Landing in Normandy (July 1346) with a well-disciplined army, he captured Caen, only to be overtaken in Picardy by a much larger French army as he moved to join his Flemish allies. At Crécy (Aug. 26, 1346), despite serious disadvantages, the English forces won the first major battle of the war. Their victory, however, proved difficult to exploit; Edward moved on to capture Calais after a long siege, but

English successes

he could then only return to England with more glory than accomplishment to his credit.

Nevertheless, Philip's failures were proving costly in money and political support. In 1340–41 he had been able to raise "extraordinary" revenue through taxes on sales, salt, and hearths, despite regional protests. The continuance of sales and salt taxes in 1343 could be extracted from the Estates of Paris only in return for the restoration of a stable coinage; in the following years regional assemblies in the north proved even more obstinate. In the Estates of Paris in November 1347 the king heard ringing denunciations of his mismanagement and defeats and was fortunate to obtain new subsidies to support an invasion of England. But that prospect, like the war itself, evaporated when the Black Death struck Europe late in 1347, destroying life, fiscal resources, and resolve for several years thereafter.

Philip VI cannot be judged by his military failures alone. The royal domain was significantly enlarged by his acquisition of Dauphiné (technically an endowment for his grandson in 1343–49) and the city of Montpellier, the last (and wealthiest) Aragonese fief in Languedoc. As administrative expertise continued to progress, the services, such as Parlement and treasury, were regulated. Within the departments of the court and notably in the Chamber of Accounts, power came increasingly into the hands of royal favourites, whose rivalries were stimulated by the courtly predilections of the king. Their influence and peculation together with the familiar injustices of local government came under attack in the Estates of 1343 and 1347, which, in their conditional grants of subsidy, asserted a more nearly constitutional authority than French assemblies had yet enjoyed; the fiscal powers of the provincial Estates likewise originated during this reign.

John the Good. John II the Good (ruled 1350–64) succeeded to a weakened authority and kingdom; he was a mediocrity whose suspicions and impetuosity were ill suited to the changed circumstances. John hoped to rally baronial loyalties to himself. But he failed to reconcile Charles the Bad, king of Navarre, whose strong dynastic claim to the throne (he was the grandson of Louis X) was matched by his ambition; Charles's conspiracy—at first appeased, then too violently put down—seriously weakened John during the years (1355–56) when the English war broke out anew. When Charles sought alliance with Edward III, French diplomats abandoned full sovereignty over Aquitaine, a reversal of policy too gratuitous to hold for long; its prompt revocation, with papal support, encouraged Edward's son, the Black Prince, to undertake destructive raids through Languedoc in 1355. That November the Estates of Languedoïl, meeting at Paris, insisted on controlling the military appropriations they voted; when the Black Prince advanced from Bordeaux to Touraine in the summer of 1356, John hastened to prevent his union with rebellious Norman barons. The afmies met near Poitiers in September. Once again the French had the advantage of numbers and position, only to suffer a disastrous defeat. King John allowed himself to be taken prisoner.

The regency of the dauphin Charles

France was to experience no worse years than those of the regency, during John's captivity, of the dauphin Charles (1356–61). Unpaid or poorly disciplined armies ravaged the countrysides. The dynasts, nobles, and townspeople had new reasons to resist the monarchy. The dauphin showed no sign of adjusting to meet the crisis; the Estates-General convoked in 1356 to provide for the king's ransom demanded sweeping administrative reforms, even imposing upon the regent a council representing the Estates. Their program proved unworkable, and Charles tried to resume power on terms already rejected by the Estates. This move radicalized Étienne Marcel, provost of the Parisian merchants and leader of the urban estate. Causing the brutal murders of two of the dauphin's noble associates, Marcel only succeeded in creating an irreconcilable breach with the dauphin, who fled Paris and convoked his own assembly at Compiègne. Marcel's enthusiasm mounted as his position became more precarious; he drew strength from alliance with Charles the Bad but failed to win the Flemish towns to his cause. The climactic complication was a terrible uprising of the peasants (the Jacquerie), which broke out in Picardy in May 1358 and which antagonized Marcel's noble supporters, notably Charles the Bad, who helped to quell the disturbances. Marcel was increasingly isolated when loyalist sentiment mounted and administrative failures became evident. His assassination on July 31, 1358, not only secured the dauphin's authority but ended the burgher influence that had originated in the Estates of 1355.

Efforts to end the war

Intense efforts were then made to end the English war. Negotiations dragged past the term of truce set in 1356; when a first and too humiliating treaty was rejected by the dauphin, Edward made yet another demonstration in France (1359). At Brétigny (May 8, 1360) King John's ransom was set at three million gold crowns, while to England was assigned full sovereignty over Aquitaine (including Poitou). Two months later John arrived in Calais, where a first payment of ransom was made. In the definitive Treaty of Calais (Oct. 24, 1360), for reasons not clear, the monarchs' renunciations—Edward's claim to the crown of France, John's to sovereignty over the ceded territories—were postponed. The Black Prince, however, proceeded to take control of Aquitaine, while the regent tried with little success to extract additional money for the ransom from an exhausted country. When the Estates at Amiens (October 1363) refused to ratify an irresponsible agreement between the king's replacement hostages and Edward III, John returned to captivity in London, where he died a few months later.

Charles V. Under the former dauphin, now Charles V (1364–80), the fortunes of war were dramatically reversed. Charles had a high conception of royalty and a good political sense. While he shared the Valois taste for luxury and festivity, he reverted to the Capetian tradition of prudent diplomacy. He observed the Treaty of Calais, which helps to explain why Edward III did not press to conclude the renunciations; but he reserved his authority in Aquitaine by inserting in his coronation oath a clause prohibiting the alienation of rights attaching to the crown.

The early years of his reign were filled with baronial politics. Charles the Bad once again revolted unsuccessfully, his dynastic claim to Burgundy running afoul of the king's; the succession to Brittany was settled by arms in favour of the Anglophile Jean de Montfort (who became John IV the Valiant). Most significant for the future, Charles V obtained the heiress to Flanders for his brother Philip the Bold, to whom Burgundy had been granted in appanage. Meanwhile, companies of mercenary soldiers, many based in strongholds of central France, were paralyzing the countrysides. Charles V commissioned the Breton captain Bertrand du Guesclin to neutralize them. Between 1365 and 1369 Bertrand employed the companies in adventurous conflicts in Spain; many of the mercenaries were killed or dispersed. The Black Prince had also intervened in Spain, and his taxes and administration in Aquitaine aroused protest. In 1369 the lords of Albret and Armagnac, having refused to permit levies of subsidy in their lands, appealed to Charles V for the judgment of his court. Although Charles hesitated, his eventual decision to accept the appeals was in keeping with the letter of the Treaty of Calais and his coronation oath.

French successes

The war with England soon broke out again. Two new factors worked in favour of France. First, Charles's alliance with Henry II of Trastámara, king of Castile, cost the English their naval supremacy; a Castilian fleet destroyed English reinforcements off La Rochelle in 1372, which effectively secured the success of French operations in the west. Second, Charles abandoned the defective policy of massive engagement with the enemy. Unable to command in person, he appointed Bertrand du Guesclin constable in 1370; the latter proceeded to harry the enemy and to prey on supplies with great effectiveness. Through skirmishes and sieges, the French forces soon reconquered Guyenne and Poitou, leaving only some port towns (Calais, Cherbourg, Saint-Malo, Bordeaux) in English hands. To finance these operations, Charles continued to levy the taxes on merchandise, salt (*gabelles*), and hearths that had been intended to raise John's ransom; despite serious inequities and defaults, these taxes persisted to the end of the reign. In Languedoc they were voted, assessed, and expended by the Estates; elsewhere, by transforming the deputies first chosen by the Estates in the time of John into royal officers, Charles created a fiscal administration independent of popular control. His military success owed much to the improved regulation of armed forces and defenses. Ordinances provided for the inspection and repair of fortifications, the encouragement of archery, a more dependable discipline, pay for fighting men, and even the establishment of a navy.

The last years of the reign brought disappointments. Truces were arranged; but, as there could be no more talk of ceding French sovereignty over Aquitaine, there could be no assurance of peace. More serious, the papal–French alliance collapsed. Charles V, unable to prevent Pope Gregory XI from returning to Rome in 1376, chose to support the candidacy of Robert of Geneva against the Italian Urban VI in 1378, but only Scotland and Naples followed the French lead. A schismatic pope could no longer help France much; rival popes could hardly promote peace between their political supporters. Although he had reestablished the political unity of France, Charles V left an uncertain future.

Charles VI. Charles VI (ruled 1380–1422) was a minor when he succeeded his father. His uncles, each possessed of the ambition and resources to pursue independent policies, assumed control of the government. Duke Louis of Anjou soon removed himself from influence by seeking the throne of Naples; Jean, Duke de Berry, received the lieutenancy of Languedoc, by then virtually an appanage; and it was left to Duke Philip the Bold of Burgundy to set the young king's policy. He imposed his own cause upon the king in his policy toward Flanders (whose ruler, Count Louis II, was Philip's father-in-law). An uprising by the workers of Ghent, spreading to other towns, was met by royal force that won a crushing victory at Roosebeke in 1382. The young king returned in triumph to deal forcefully with restive populations at Paris and Rouen and in Languedoc. The provostship of the merchants was suppressed at Paris, bringing that municipality under direct royal control.

In 1388 Charles VI assumed full authority himself. He recalled his father's exiled advisers, the Marmousets, who undertook to reform the royal administration in keeping with the practice of Charles V. But the country was again wearying of taxation. The annual levies of Charles V had been discontinued in 1380 but then reestablished—helping to cause the urban unrest already mentioned—and were being dissipated blatantly in royal and princely extravagance. In 1392 the king lost his sanity, a shocking event that aroused popular solicitude for the crown. His recurrent lapses into insanity, however, played into the hands of his uncles. Philip the Bold again dominated the council. Fortunately for France, England was incapable of renewing the war. The Duke of Burgundy planned an invasion of England in 1386, but after major preparations in Flanders it came to nothing. A series of truces, beginning in 1388, was followed by a reconciliation between Richard II of England and Charles VI in 1396, when the truce was extended for 28 years. Meanwhile, French nobles were reviving the crusade, imagining a reunited West following their lead; John the Fearless' defeat at Nicopolis in 1396 was the most famous of several enterprises. To restore unity in the church, the masters of the University of Paris began to speak out vigorously; the conciliar theory (according to which the church was to be governed by an ecumenical council), which finally prevailed to end the schism, owed much to them.

Insanity of Charles VI

When conflict with England was renewed in the 15th century, circumstances had changed. Henry IV of England was committed to the recovery of English rights in France; moreover, in a civil war between Louis, Duke d'Orléans, and John the Fearless (duke of Burgundy since 1404) over control of the king, both parties sought English support. And, when John caused Orléans to be assassinated in Paris (Nov. 23, 1407), the popular horror magnified the conflict. John exploited the situation by pressing for reforms; his rival's cause was taken up by Bernard VII of Armagnac, whose daughter married Orléans's son. But John's alliance with the turbulent Parisians was no more secure than the temper of the angriest burghers; a major ordinance for administrative reform (1413) collapsed in a riot of the butchers, and in the ensuing reaction the Armagnac faction regained control of Paris. John's dangerous response was to encourage the new king of England, Henry V, to claim the French throne for himself. Henry's invasion of 1415, reminiscent of the campaign ending at Crécy, had the same result—at Agincourt the French suffered yet another major defeat, after which, characteristically, the English withdrew—but the civil war in France enabled Henry V to exploit his strength, as Edward III had not been able to. In 1418 the Burgundian party recovered control of Paris, and the dauphin Charles embarked on a long exile in Armagnac company.

But John's duplicity was limitless; while meeting with the dauphin to betray the English, John was himself assassinated (1419). His successor, Philip the Good, renewed the alliance with Henry V. By the Treaty of Troyes (1420) the deranged Charles VI was induced to set aside the dauphin's right of succession in favour of Henry V, who married Charles VI's daughter. The ancient dream of a dynastic union between France and England seemed to be realized; and, when Henry and Charles died within weeks of each other in 1422, the infant Henry VI became king in both lands.

Charles VII. Charles VI's son, Charles VII (ruled 1422–61), for his part, did not fail to claim his inheritance, though he had no proper coronation. Residing at Bourges, which his adversaries pretended was the extent of his realm, he in fact retained the fidelity of the greater part of France, including Berry, Poitou, Lyonnais, Auvergne, and Languedoc. For a time the Valois cause suffered from the ineptness of its leader and from his advisers and retainers, who prospered from the unresolved conflict. Incapable himself of military leadership, Charles put his hope in reconciliation with Philip of Burgundy, a diplomacy that thoroughly discomfited King Henry's regent, the Duke of Bedford. Nevertheless, French prestige collapsed with the abasement of the monarchy; Charles VII appears to have doubted his own legitimacy, and disorders spread again.

Joan of Arc

Then Joan of Arc appeared. Stirred by the popular memory of traditional French kingship, she found her way from her peasant home at Domrémy (on the border of Champagne and Bar) to Chinon, where she confronted Charles with her astonishing inspiration: her "voices" proclaimed a divine commission to aid the king. In April 1429 she entered Orléans, long besieged, rallying the garrison to effective sorties that soon caused the English to lift the siege. Other victories followed, in which Joan's influence was manifest, although probably exaggerated in tradition. On her insistence that only consecration at Reims could make a true king, chosen by God (a view doubtless supported by the chancellor Regnault, archbishop of Reims), it was decided to advance boldly across the Île-de-France to Reims. Charles was anointed there on July 17, 1429.

Recovery and reunification, 1429–83. The coronation of Charles VII was the last pivotal event of the Hundred Years' War. From Reims the king's army moved on triumphantly, winning capitulations from Laon, Soissons, and many lesser places and even threatening Paris before disbanding. The popular devotion to monarchy that had produced Joan was undermining English positions almost everywhere in France; the urgent necessity to discredit her explains the callous efficiency of the inquisition to which she was subjected upon being captured by the Burgundians and turned over to the English in 1430. Condemned of heresy, confessed under duress, boldly relapsed, she was burned at the stake in Rouen on May 30, 1431.

Charles and his party made no move through ecclesiastical channels to save Joan. They then proceeded deliberately to make peace with Burgundy. In the Treaty of Arras (Sept. 21, 1435), Philip the Good bargained strongly; confirmed in the possession of domains ceded by the English, he also obtained Charles' humiliating disavowal of the murder of the duke's father, John the Fearless. The act, however damaging to the royal vanity, set Charles free from political obligation to the Armagnacs; the factional king now became the supreme king of France. Within a year, English support collapsed in the Île-de-France, and royal soldiers entered Paris. The Truce of Tours (1444) provided for a marriage between Henry VI and the niece of Queen Mary of France; extensions of the truce gave Charles time to strengthen his military resources. War flared again in 1449, when England intervened against a duke of Brittany who had done homage to Charles VII. In 1449–50 a vigorous campaign resulted in the French conquest of Normandy, and in 1451 most of Guyenne fell to the French.

The end of the Hundred Year's War

When the English lost the minor battle of Castillon in 1453, the Hundred Years' War was over. That fact was not altogether clear to contemporaries, for no treaty was concluded and skirmishes were to recur for many years to come. But only Calais, enclosed in the Burgundian domains, remained of English possessions in France. Charles VII issued medals to commemorate his soldiers, and he ordered a review of Joan of Arc's trial, which resulted in a verdict of rehabilitation in 1456.

Governmental reforms. As hostilities were waning (1435–49), Charles VII presided over a major reorganization of government. Tested by adversity and strengthened by fortune, he had grown in political competence. The principal administrative services—chancery, Parlement, accounts—were reestablished at Paris. The replacement of Burgundian sympathizers, notably in Parlement, seems to have been accomplished with moderation and tact; in local offices no purges were necessary. But it quickly became evident that the reunited country was now too large and its officials too numerous to get along very well with a government as centralized as Parisian bureaucrats preferred.

Remedial legislation was consistent with tendencies long apparent. Revenues from the domain were collected in the treasury, the work of which Charles VII reorganized in four regional offices. Extraordinary revenues had been administered since the 1350s in districts (*élections*), the numbers of which had vastly increased since the time of Charles V. The *élections* were now subordinated to four regional *généralités*, corresponding to the offices of treasury. The old Chamber of Accounts had lost parts of its jurisdiction to more specialized courts in 1390, of which the Cour des Aides (board of excise) had provincial divisions set up at Toulouse in 1439 and at Rouen in 1450. A provincial *parlement* was definitively established at Toulouse in 1443, and there were to be others at Grenoble and Bordeaux. With all these changes the conciliar structure of government survived; policy continued to be made by the king in concert with favourites, whose numbers no reforms had delimited. The proliferation of lesser offices, many filled by lawyers, created a new stratum of gentlemen who enjoyed the king's privilege.

Revenues

While the reform of offices did nothing to obliterate the older distinction between ordinary and extraordinary revenue, the work of Charles VII effectively belied the notion that the monarchy should subsist on its domain alone. That the king as lord could no longer pay his officers and soldiers was apparent to almost everyone. Early in his career Charles had resorted to the Estates to raise *aides* and *tailles* (as the old levies on sales and hearths were now called), but after convocations in the 1430s he continued these taxes through annual ordinances no longer sanctioned by the Estates. Moreover, the preparation of annual budgets for ordinary and extraordinary revenues gave way in 1450 to a single "general statement" of finance, which, being related to demonstrable necessities, effectively institutionalized taxation in France. As the Middle Ages ended, France comprised a central core of *élections*, where local Estates, when they met at all, had little to do with fiscal matters, and a surrounding belt of "lands of Estates" (*e.g.*, Languedoc, Brittany, Normandy, and Burgundy), where custom continued to allow for consent or for the administration of taxes. Having originated in times of

France in 1453.

fiscal demands thought uncustomary and excessive, representative institutions could not generally survive once the royal impositions, from very repetition, had ceased to seem arbitrary; even where Estates persisted, their votes were more like approval than sovereign consent.

The new standing army

Military reforms. The fiscal reorganization facilitated equally significant military reforms. The Peace of Arras, rather than pacifying France, had only thrown the people once again to the mercies of disbanded mercenaries and brigands. In 1439 an ordinance made the recruitment of military companies the king's monopoly and provided for uniform strength in contingents, supervision, and pay. Following the Truce of Tours in 1444, no general demobilization occurred; instead the best of the larger units were reconstituted as "companies of the king's ordinance," which were standing units of cavalry well selected and well equipped; they served as local guardians of peace at local expense. With the creation of the "free archers" (1448), a militia of foot soldiers, the new standing army was complete. Making use of a newly effective artillery, its companies firmly in the king's control, supported by the people in money and spirit, France rid itself of brigands and Englishmen alike.

Regrowth of the French monarchy. Thus the monarchy recovered much of the authority it had lost during the early stages of the Hundred Years' War. Although its influence in Burgundy and Flanders, now united in a formidable dynastic association, had declined, its definitive recovery of Aquitaine consolidated a direct domain, again extensive enough to free the Valois from anxiety about landed resources. It had exploited not only a widespread distaste for the destructive self-interest of barons and warlords but also an incipient nationalism, which, besides reviving the "religion of monarchy," put new stresses on the foreignness of Englishmen. How renewed power and Gallicanism went together was demonstrated in the Pragmatic Sanction of Bourges (1438), by which papal benefices and revenues from France were severely curtailed and the royal influence in the French church strengthened. Nevertheless, the survival of powerful dynasts and provincial interests, as a legacy of the war and the fertility of the royal house, represented a counterpoise to the crown that Philip the Fair had never known. And, with the son of Charles VII, the monarchy was to be tested yet again.

The tyranny of Louis XI

Louis XI (1461–83) was shamelessly impatient for his father's death. It must be said of this strange man that he had worthy policies to pursue: the securing of the royal domain against Burgundy, Orléans, and Brittany, among others, and the promotion of commerce and industry within national boundaries. His foreign policy was less consistent, ranging from the cautious in Italy to the chimerical in Spain; yet it was at the expense of Aragon that he regained title to Roussillon and Cerdagne. His methods rather than his ends were what made the reign of this ambitious, nervous, and capricious ruler so turbulent. No French king had ever imposed himself so totally and so tyrannically as Louis XI. Forgetful of past loyalties, he was betrayed as often as he himself betrayed others. Toward the clergy as toward his officials he could be brutal and vindictive. He antagonized the nobles by revoking the Valois pensions and ceremonial and by promoting the independence of seigneurial towns. As for the royal towns, Louis respected their constitutions only so far as was consistent with royal supervision and the payment of heavy taxes; he tolerated the resurgence of urban oligarchies. Fiscal pressures in support of the army, government, and diplomacy mounted fearfully.

Politics, under Louis XI, replaced administration as the foremost preoccupation of the realm. Arbitrary and hasty measures against the dynasts aroused the formidable League of the Public Weal, which, in 1465, appealed to the people against misgovernment and proposed a regency of the princes supported by the three estates. Louis, in turn, as on later occasions, used assemblies and proclamations to divide the princes. But the settlement of October 1465 was a grave setback for the king, whose brother Charles gained title to Normandy while Charles the Bold, soon to inherit Burgundy, acquired strategic counties and towns in Artois. To the undoing of this treaty Louis devoted great energy. Fomenting strife between Brittany and Normandy, he soon recovered the latter and isolated the former. Deaths among his rivals in Gascony enabled him to secure successions, as in Armagnac, more divided and less hostile. Increasingly, Louis's tortuous diplomacy fastened on Burgundy. The king succeeded in reconciling the Swiss cantons with Austria to form a coalition with France and the Rhenish cities; this coalition invaded Burgundy and defeated and killed Charles the Bold at Nancy (Jan. 5, 1477). While the legal reversion of Burgundy to the crown could not be given practical effect, Louis did recover Artois. Moreover, even as he enjoyed this decisive triumph over his most dangerous rival, the entire Angevin inheritance (Anjou, Provence, and Mediterranean claims) devolved to the crown upon the death of René of Anjou in 1480. Through accident and design and the inability of the princes to collaborate effectively, Louis had succeeded in countering the threat of a princely constitution and had considerably extended the royal domain.

Economy, society, and culture in the 14th and 15th centuries. The long war, fought almost entirely in France, benefited few but the captains and peculators; it injured almost everyone. Even the best disciplined companies lived off the land, so that French peasants and defeated townsfolk in effect paid the expenses of both sides; and undisciplined mercenary bands were a wearisome scourge in times of truce after the middle of the 14th century.

Economic distress. But the war did not alone cause economic distress. Even before it broke out, bad weather and commercial dislocations, together with overpopulation in some areas, resulted in worse famines and more frequent ones than in the past. But what most terribly damaged life and security was sickness.

The Black Death

The Black Death, carried on shipboard from the Levant, reached Provence in 1347, ravaged most of France in 1348, and faded out only in 1350. Nothing worked to check the disease in populations without immunity—neither bonfires to disinfect the air, nor collective demonstrations of penitence in northern towns, nor persecutions of Jews or friars. The mortality was staggering—the French chronicler Jean Froissart's estimate that the first wave carried off a third of the population was perhaps not far wrong; evidence shows that rural areas were no less afflicted than towns. And there were recurrent outbreaks of plague in later years. These afflictions and related factors were responsible for a general decline of population. Toulouse seems to have lost half of its population, which fell from 40,000 to 20,000; the population of Normandy is estimated to have declined by two-thirds between 1300 and 1450. The trend was probably reversed, and perhaps strongly so, in the second quarter of the 15th century, although little is yet known about this.

The hard times affected classes and regions in different ways, degrees, and rhythms. Some places almost escaped the ravages that afflicted others repeatedly. In the countrysides, especially—save for the greatest personages—those who had most to lose suffered most. Whether for landlords or rich peasants, surpluses became harder to obtain or preserve; to many lesser lords the dangerous fortunes of war probably seemed an attractive alternative to declining yields in money or produce. Standards of living, as measured in diets or furnishings, declined. Onerous obligations and services tended to disappear as shortages of rural labour made themselves felt; the transition from servile to rental tenures was largely completed in the 15th century. Peasant uprisings, such as the Jacquerie in the relatively prosperous Île-de-France and the Tuchins in Languedoc, are too poorly documented to be well understood—both betrayed desperation born of recurrent taxation and were associated with the expression of egalitarian ideas; the Jacquerie coincided with a weakened grain market and may have been hastened by efforts of lords to enforce labour services and payments after the Black Death. The manor survived, but little remained of its human identity in the 15th century. Even minor lords lived away from their peasant tenants, protected them poorly if at all, relied on salaried managers to collect payments that, in some cases, had lost all social justification; lordship had degenerated into an unsentimental economic practice.

The cities. Urban society was also troubled. The walled town stood out ever more starkly against the countryside as siege warfare intimidated or destroyed the suburbs that had been built in a less anxious day. Royal taxation, often inequitably administered, exacerbated old tensions in the towns; fiscal policy or the regulation of wages or supplies was largely at issue in the uprisings of Flemish towns (1323–28), at Paris (1357–58, 1380–82), and at Rouen (1382). Communes continued to be revoked in the 14th century, although the kings as a rule were less interested in governing the towns than in securing their resources and fidelity. The concentration of trades and crafts in guilds became more complete and more exclusive.

Decline of commercial centres in the 13th century

Some leading commercial centres of the 13th century suffered as new trade routes developed in the empire and by sea and as textile manufactures and money markets—the latter suffering from unstable coinages—became more dispersed. The fairs of Champagne declined rapidly after 1310. Only a few capitals, such as Avignon, Bordeaux, and Paris, prospered; and even they were hard hit by plague. Nor did the French merchant or manufacturer progress competitively; his work often unspecialized, his bookkeeping old-fashioned, his tastes simple, he typically looked forward to securing his future by the purchase of land.

Form of Christian piety

The church. The organized church, despite losses from war and plague, continued to be better endowed economically than morally. The popes of Avignon were less distant and—save perhaps to their French relatives, merchants, and artists—less admirable than the reformer popes of the past; as the prestige of their schismatic successors plummeted, the higher clergy were confirmed in their incipient Gallicanism (a movement advocating administrative independence from papal control). While organized heresy had almost disappeared, reforms intended to strengthen the parish priesthood languished. Jurisdictional disputes continued to rage between mendicants and seculars and between bishops and canons or archdeacons. Christian piety even more than in the past sought encouragement in mystical or individual devotions or readings and in collective observances of the Holy Spirit or the Virgin or the patron saints of the trades that promoted elementary solidarity and charity in the towns; such confraternities were not always welcome to ecclesiastical authorities, whose deportment or jurisdiction they sometimes challenged, whether directly or merely by example. The popular religion of saints—more particularly of the Virgin and the Pietà—and fear of demons worked more deeply into the collective imagination, becoming very evident in the 15th century. Associated with intensified anxieties about sin and damnation, these experiences thrived in times of recurrent and inscrutable disaster.

Culture and art. Cultural circles remained strongly oriented to aristocratic values and the past. With the accession of the Valois came a high nobility, distinguished by lavish and exclusive conceits. When John II formed the Order of the Star (1351), an institution imitated by the great lords for their clientages, chivalry stood incorporated as the most distinguished of religious confraternities. The ideal of the crusade remained strong, notably among princes of the fleur-de-lis, who dominated the public life of Valois France to the point of eclipsing the monarch; beneath them many noble families disappeared, while new ones emerged among the captains, lawyers, and patricians. Froissart spun out chronicles of the war at once detailed and grand, full of the frivolous ceremonial that marked the aristocratic life of his day. Tapestries created for courtly patrons idealized a life of enticing gardens, tournaments, and the hunt. Paintings as well as tapestries decorated the walls of chambers that were smaller and more elegant than the cavernous halls of earlier centuries. The rayonnant Gothic of the Île-de-France remained in favour through the 14th century, inspiring the chapel built by Charles V at Vincennes, while the decorative arts of furnishings and manuscripts exploited the Gothic tendencies to articulation and grace. The evocation of the classical past became less fantastic and more heroic in the humanist circles of Pierre Bersuire and Petrarch; their interests helped to attract copyists and artists to the papal court of Avignon. The *Book of Hours* (the most popular private devotional work of the later Middle Ages) might become "very rich," as in the case of a sumptuous manuscript undertaken for Jean, Duke de Berry (*c.* 1410); more typically it was a pocketbook for general use by the literate, whose numbers continued to increase.

Music

Stimulated by the commissions of Charles V, the chasm between learned and vernacular cultures narrowed: Raoul de Presles translated St. Augustine; Nicole Oresme translated Aristotle. Music resounded in old forms (ballad, virelay) even while becoming more articulate or flamboyant; Guillaume de Machaut (d. 1377), the great musician-poet of the mid-14th century, composed the first polyphonic mass as well as many motets and secular lyrics. Time and space came to be better represented and measured, as evidenced by the first attempts to render perspective in art and in the erection of public clocks at Paris and Caen.

Toward 1400 Paris regained cultural leadership as a result of a new synthetic (or international) style in painting and of the initiatives of the university masters in ecclesiastical politics and theology. The efflorescence, however, was soon destroyed in the civil wars, to be succeeded later in the 15th century by more provincial activities. Universities (like *parlements*) proliferated at the expense of Paris, which became the preserve of an antiquated and pedantic theology. Painters, architects, and writers regrouped under princely patrons or even under bourgeois ones, flourishing in postwar trade (Jacques Coeur's palace at Bourges exemplifies the flamboyantly decorated solidity of late-medieval taste in France). A new style in painting, as in architecture, characterized by vigour and an enlarged scale, contrasted with the more traditional style in Burgundy, where the dukes were building on a grand and continuous past. Italianate humanism, together with the new philology, stirred in France only in the latter third of the 15th century. (T.N.B.)

France, 1490–1715

FRANCE IN THE 16TH CENTURY

When Charles VIII (1483–98) led the French invasion of Italy in 1494, he initiated a series of Italian wars that were to last until the Peace of Cateau-Cambrésis in 1559. These wars were not especially successful for the French, but they corresponded to the contemporary view of the obligations of kingship. They also had their effects upon the development of the French state; in particular, they threatened to alter not only the military and administrative structure of the monarchy but even its traditional role.

Military and financial organization. The French kings of the early 16th century could look back with satisfaction at the virtual expulsion of the English from French soil in the course of the preceding century. This success offered a shining precedent for further military sallies, this time against the growing power of the Habsburgs. In 1445 the first steps had been taken to fashion a royal French army out of the ill-disciplined mercenary bands upon which French kings had traditionally relied. It was a small force—no more than 8,000 men—but it was a beginning. The role of the nobility in the army was strong, for the art of war was still considered a noble pursuit par excellence. The core of Charles's army that marched into Italy, the *compagnies d'ordonnance,* known collectively as the *gendarmerie,* consisted of noble volunteers. The infantry, however, was made up of nonnobles, and by the middle of the 16th century there were more than 30,000 infantrymen to a mere 5,000 noble horsemen. As this infantry force grew in number, its organization changed. Legions, organized on a strict provincial basis (the Breton Legion, the Norman Legion, etc.), gave way to the regimental system, based on large units under a single command. This latter organization appeared during the Wars of Religion of the 16th century and survived until the time of Louis XIV. Of great significance, too, was the involvement at the heart of the royal army of the provincial governors as commanders of the *gendarmerie.* Yet such reorganization did not immediately reduce the army to a pliant tool of the crown. Not until late in the 17th century could the royal army be considered fairly under the king's control. Until then, notably during the Wars of Religion and the outbreaks of the Fronde (1648–53; see below), the loyalty of the commanders and the devotion of the troops were conspicuously inadequate. In the later part of the 17th century, the reforms of the army by Michel Le Tellier and his son the Marquis de Louvois provided Louis XIV with a formidable weapon.

The problem of royal finance

The growth of a large royal army, however, was only one effect of the increased level of military activity. The financial administration of the country also underwent a drastic reorganization, which had far-reaching economic and social consequences. The king, despite his ambitions, possessed neither the resources nor the administrative machinery to maintain a large army. The medieval idea that the king should live off the revenue of his own domain persisted into the 18th century and helps to explain the formal distinction made until the reign of Francis I (1515–47) between ordinary and extraordinary finance—*i.e.,* between revenue emanating from the king's patrimonial rights and taxes raised throughout the kingdom. By the reign of Francis I, the king, even in times of peace, was unable to make do with his ordinary revenue from rents and seigneurial dues. In 1523 Francis established a new central treasury, the Trésor de l'Épargne, into which all his revenues, ordinary and extraordinary, were to be deposited. In 1542 he set up 16 financial and administrative divisions, the *généralités,* appointing in each a collector general with the responsibility for the collection of all royal revenues within his area. In 1551 Henry II added a treasurer general; from 1577 the *bureaux des finances,* new supervisory bodies composed of a collector general and a number of treasurers, made their appearance in each *généralité.*

The taille

The actual collecting of taxes, moreover, was increasingly handed over to tax farmers. The more efficient methods of collection by tax farmers enabled the crown to gather a larger proportion of its revenue than previously but did not solve the problem of royal finance. Even the extraordinary taxes, now added to the crown's ordinary revenue, notably the taille (a direct tax levied on all but the nobility and the clergy), custom duties, and the purchase tax on wine, fish, meat, and especially salt (the gabelle), were not adequate resources for Renaissance princes whose chief glory lay in the expensive art of war. The taille, the only direct tax, which weighed most heavily upon the underprivileged classes, went up from about 4.5 million livres under Louis XI (1461–83) to 55 million under Jules Cardinal Mazarin in the mid-17th century.

Successive monarchs were forced, therefore, to seek additional revenue. This was no simple matter because French kings traditionally could not tax their subjects without their consent. Indeed, there were many areas of the country where the taille itself could not be collected and where the king was dependent upon local agreements. The early Valois kings had negotiated with the Estates-General or with the provincial Estates for their extra money; but in the middle of the 15th century, when the Hundred Years' War with England was reaching a successful conclusion, Charles VII was able to strike a bargain with the Estates. In return for a reduction in overall taxation, he began to raise money to support the army without having to seek the Estates' approval. In some areas of central France the provincial assemblies ceded their right to approve taxation and disappeared altogether. These provinces were known as the *pays d'élection.* But, in those provinces where the provincial Estates survived (the *pays d'état*), the right to vote the amount of royal taxation also survived. During the Italian wars, meetings of the Estates became more frequent as the king's financial demands became more strident, and, though the Estates never felt themselves able to refuse to provide money, they retained the right to provide less than the monarch asked for. The king continued to rely upon the support of the provincial assemblies to provide extra revenue long after 1614, when the cumbersome Estates-General ceased to play a role in opposing financial resources for the crown.

The sale of offices

The growth of a professional bureaucracy. But the king also found another means of filling his exchequer that had nothing to do with traditional methods: he began to sell offices on a large scale. Venality, or the sale of offices, was not novel in early 16th-century France; traces of the practice can be found in the 13th century. But it was Francis I who opened the floodgates. The number of judges proliferated. In the Parlement of Paris alone the king created two new chambers, each containing 20 members and a further score of judges. In 1552 Henry II established a new kind of court, the *présidial,* whose jurisdiction lay between the *parlement* and the bailiwick. Each of the 65 new courts had a complement of nine judges; this brought in a sizable revenue but appears to have made little difference to the efficiency of the judicial system. Nor were judicial offices the only ones put up for sale; it was also possible to purchase financial offices, such as those of treasurer general, treasurer, or the immediately inferior *élu.* It has been estimated that during the 16th century some 50,000 offices were sold by the crown.

The partial rationalization of the financial system produced an increasing number of professional advisers, who formed the embryo of a bureaucratic elite. In the course of the 16th century, as specialization grew apace, the king's council became a much more complex institution. The Conseil d'État, with its various subdivisions, formed the hub of royal government. Its members were drawn from a variety of backgrounds. The king's immediate family expected to be consulted, as did great officers of the crown, such as the chancellor, the constable, and the admiral. Also included in the council were the great territorial magnates, members of powerful aristocratic families, and the country's leading prelates. There were also masters of requests (*maîtres des requêtes*), lawyers whose expertise was invaluable when the council sat in a judicial capacity. But in the council the professional element that assumed the greatest significance in the course of the 16th and 17th centuries were the holders of the office of secretary of state. In the early years of the 14th century, royal secretaries had already acquired the right to sign documents on the king's authority. From this stage, granted the stability of the crown, the development of the office from a position of subordinate but considerable importance to one of complete indispensability was predictable. Henry II gave four of his secretaries the official title of *secrétaire d'état,* and in 1561 they became full members of the royal council. Closely associated with them and destined to overshadow them in importance in the first half of the 17th century were the superintendents of finance, formally established in 1564, though exercising an already well-established function. Their responsibility was to control and safeguard royal finances and especially to prepare annual budgets containing estimates of revenue and expenditure for the following year. They also played a leading part in assessing the amount to be levied each year from the taille and in deciding upon the imposition of new taxes. Below the superintendents but also in the royal council in the 16th century were the intendants of finance. Originally masters of requests, they became a separate group specializing in the increasingly complex task of advising the sovereign in financial matters. In time, their role outstripped in prestige that of the other masters of requests who counseled the king.

The new administrators

There thus grew up a more specialized class of administrators, close to the crown, whose expertise rather than birth was the key to their influence; the sale of office allowed wealthy families to establish a firm base for later political and social advancement. In addition, the needy crown was perfectly prepared to sell titles of nobility as well as offices and, in return for a cash payment, to allow both nobility and office to become hereditary. Although this advancement of new men within the government might suggest a social readjustment of considerable proportions, in fact the element of continuity was more important than might at first appear. Even though it is true that some of the ancient noble families and the king's own relatives found it increasingly difficult to fulfill their old advisory roles, the new men were not rejecting the established order but rather were being absorbed into it. The king's counselors, whatever their former background, became leading noblemen by virtue of their high office: service to the crown was what mattered, and elevation to the office depended on the king's choice. It was not the first time that a new wave of royal servants had begun to overtake established advisers; in the 13th century the *magistri* had ousted the great barons and prelates from the Curia Regis without effecting a social revolution. What took place in the 16th and 17th centuries was another turn of the social wheel by which new men seized the opportunity to pursue those dignities and honours held by men who were themselves descendants of new men.

Jacques Lefèvre d'Étaples

The Reformation. The professional class that grew up in the 16th century, however, was different in one respect from those that had gone before: it represented a predominantly secular culture—the product of Renaissance humanism. Nevertheless, in the second half of the 16th century the Reformation was to embroil France in a series of religious wars that were to pose a serious threat to the power of the king and his government. Lutheran works first appeared in Paris in 1519; in 1521 Francis I, who was on the point of war with Emperor Charles V and King Henry VIII of England and who wanted to demonstrate his orthodoxy, forbade their publication. Yet, interest in the new faith continued to grow, especially in the humanist circle of Jacques Lefèvre d'Étaples. Lefèvre, who had in 1512 published an edition of the letters of St. Paul with a commentary that anticipated Martin Luther in its assertion of the doctrine of justification by faith, became the leader of a small group of moderate but orthodox reformers in the tradition of the great Dutch humanist Desiderius Erasmus. This group included Guillaume Briçonnet, the bishop of Meaux; the mystic Gérard Roussel; and Margaret of Angoulême, the king's own sister. Although this circle was dispersed in 1525, Lutheranism had already established itself, especially in such trading centres as Lyon where it found support among the poorer classes. The progress of the Reformation in France depended on the crown's attitude; although Francis for political reasons had initially shown hostility, his feelings were far from clear. He was favourably disposed toward Lefèvre and toward orthodox reform in general, though he naturally feared those extreme movements that threatened social upheaval. In addition, Francis I saw political advantages in establishing good relations with the Lutheran German princes. On the other hand, unlike them, he had no great incentive to assert his independence from Rome because the Gallican church already enjoyed a large measure of autonomy. In 1516 the Concordat of Bologna had given the king effective control over the church in France.

The influence of Calvinism

In 1534, however, royal policy changed radically. Anti-Catholic placards began to appear in Paris and other major French towns, provoking a bitter Catholic reaction and a series of persecuting edicts. French Protestantism itself had changed, reinforced from the mid-1530s by the spread among the poorer classes of Languedoc and the seaboard towns of Normandy and Brittany of the ideas of John Calvin, a French exile in Geneva. Henry II (1547–59) pursued his father's harsh policies, setting up a special court (the *chambre ardente*) to deal with heresy and issuing further repressive edicts, such as that of Écouen in 1559. Yet the infusion of French Calvinism, or Huguenotism, into the French Reformation stiffened the Protestant opposition. Protestant pastors, trained in Geneva, infiltrated into the country; by 1562 there were some 2,000 highly organized Calvinist churches in France. This spectacular spread of Calvinism persuaded the queen mother, Catherine de Médicis, who was ruling in the name of her young son, Charles IX (1560–74), to abandon the repressive religious policy of Francis I and Henry II in the name of political good sense. Guided by the moderate chancellor Michel de L'Hospital, Catherine summoned the French clergy to the Colloquy of Poissy (1561), at which an unsuccessful attempt was made to effect a religious compromise with the Huguenots; in the following year she issued the Edict of January, which allowed the Calvinists a degree of toleration. These signs of favour to the Protestants brought a violent reaction from the noble House of Guise, the champions of Roman Catholicism in France. The first civil war began with the massacre by the partisans of François, Duke de Guise, of a Huguenot congregation at Vassy (March 1562).

The Wars of Religion. Guise forces occupied Paris and took control of the royal family, while the Huguenots rose in the provinces, and their two commanders, Louis I de Bourbon, Prince de Condé, and Admiral Gaspard de Coligny, established headquarters at Orléans. The deaths of the opposing leaders—the Protestant Antoine de Bourbon, King Consort of Navarre, and the Catholic marshal Jacques d'Albon, Seigneur de Saint-André—and the capture of Condé caused both sides to seek peace. After the Battle of Dreux (December 1562) the war drew to a close, despite the assassination of the Duke de Guise by a Protestant fanatic. A compromise was reached at the Peace of Amboise in March 1563: liberty of conscience was granted to the Huguenots, but the celebration of religious services was confined to the households of the nobility and to a limited number of towns.

The second war was precipitated by Huguenot fears of an international Catholic plot. Condé and Coligny were persuaded to attempt a coup to capture Catherine and Charles IX at Meaux in September 1567 and to seek military aid from the Protestant Palatinate. In the following brief war, the Catholic constable Anne de Montmorency was killed at the Battle of Saint-Denis (November 1567); the Peace of Longjumeau (March 1568) signaled another effort at compromise. This peace, however, proved little more than a truce; a third war soon broke out in September 1568. In an attempt to restore their authority, Catherine and King Charles dismissed L'Hospital in September and restored the Guise faction to favour. The edicts of pacification were rescinded; Calvinist preachers faced expulsion from France, and plans were made to seize Condé and Coligny. The former was killed at the Battle of Jarnac (1569), and the Huguenots were again defeated in that year at Moncontour. But the Catholic side failed to consolidate its successes, and yet another compromise was arranged at the Peace of Saint-Germain in August 1570.

Massacre of St. Bartholomew's Day

Coligny subsequently regained the king's favour but not the queen mother's, and he remained an object of hatred with the Guises. In 1572 he was murdered. At the same time some 3,000 Huguenots, gathered together in Paris to celebrate the marriage of Marguerite de Valois (later Margaret of France) to Condé's nephew, Henry III of Navarre, were massacred on the eve of the feast day of St. Bartholomew. This notorious episode was the signal for the fifth civil war, which ended in 1576 with the Peace of Monsieur, allowing the Huguenots freedom of worship outside Paris. Renewed fighting broke out in 1577 between Catholic and Protestant noblemen, who defied the king—now Henry III (1574–89)—in his attempt to assert royal authority. The Huguenots were defeated and forced by the Peace of Bergerac (1577) to accept further limitations upon their freedom. An uneasy peace followed until 1584, when, upon the death of François, Duke d'Anjou, the Huguenot leader Henry of Navarre became the heir to the throne. This new situation produced the War of the Three Henrys (1585–89) during which the Guise faction—led by Henri, Duke de Guise—sought to have Navarre excluded from the succession. In a welter of intrigue and murder, first the Duke de Guise and his brother Louis, Cardinal de Guise (December 1588), and then Henry III himself (August 1589) were assassinated. Henry of Navarre thus assumed the throne as Henry IV (1589–1610), the first king of France from the house of Bourbon (a branch of the house of Capet); he had to survive five more years of civil war and embrace Roman Catholicism before his position was secure. In its final stages, the war became a struggle against Spanish forces intervening on behalf of Isabella Clara Eugénie, the daughter of Philip II of Spain and Elizabeth of Valois, who also laid claim to the French throne. The Peace of Vervins (1598), by which Spain recognized Henry IV's title as king and the Edict of Nantes of the same year, granting substantial religious toleration to the Huguenots, ended the Wars of Religion.

The religious wars and the monarchy. This succession of civil disturbances brought the French state close to disintegration and posed a threat to the crown that would not be matched again until 1789. The key factor in producing this situation lay in the nature of Calvinism, which provided both a rallying point for a wide cross section of opposition and the organization necessary to make that opposition effective. Each Huguenot community created its own administrative structure to provide a tight disciplinary framework, through which the community could ensure its spiritual and material independence. The new creed attracted several elements in French society: small artisans, shopkeepers, and the urban unemployed, who were suffering in particular from steeply rising prices; many rich townspeople and professional men who thought that material advancement would be easier to procure as Calvinists; and, after the Treaty of Cateau-Cambrésis in 1559, many nobles, especially the poorer ones who had lost with the peace their best hope of wealth and status.

The social composition of Calvinists

The adherence of large numbers of the nobility had two important effects upon the movement in France: it caused many peasants to join the new creed in imitation of their noble seigneurs, thus swelling the overall number and widening its social composition, and it brought a new military element into the Calvinist communities. Under the leadership of the nobility, secret religious meetings were transformed into mass public demonstrations against which the king's forces were impotent. Such demonstrations sometimes involved upward of 20,000 people. Similarly, the administrative structure that was so important in aiding the survival of the proscribed faith was transformed into a military organization. This organization was ultimately headed by Louis, Prince de Condé, who assumed the title of protector general of the churches of France, thus putting all the prestige of the house of Bourbon behind the Huguenot cause. By doing so, he added a new dimension to the age-old opposition of the mighty feudal subject to the crown: that opposition was now backed by a tightly knit military organization based on the Huguenot communities, by the financial contributions of wealthy bankers and businessmen, and by the dedicated religious zeal of the faithful—inspired by the example of Geneva.

At a time when the threat to the crown had never been greater, the monarchy itself presented a sorry spectacle. The struggle for political power at the centre of government after Henry II's death between the families of Guise, Bourbon, and Montmorency; the vacillating policy of Catherine de Médicis; and, most important of all, the ineptitude of three successive rulers—Francis II (1559-60), Charles IX, and Henry III—meant that local government officials were never confident of their authority in seeking to curb the growing threat of Huguenotism. Indeed, the chief opposition to Protestantism came not from the crown but from the Catholic Holy League. Because of the government's inability to control the situation, local Catholic unions or leagues began to appear in the 1560s, headed by nobles and prelates. In 1576, after the Peace of Monsieur with its concessions to the Huguenots, these local leagues were fused into a national Catholic Holy League. The league was headed by the Guise family and looked for material aid to Philip II of Spain. Its chief aims were the defeat of Protestantism in France and the restoration of ancient feudal rights and privileges. It sought, like the Protestants, to attract mass support; its clandestine organization was built around the house of Guise rather than the monarchy, from which it was increasingly alienated. In 1577 Henry III tried to nullify the league's influence, first by putting himself at its head and then by dissolving it altogether. This maneuver met with some success.

But in 1585, when the death of Henry's brother, who had succeeded him as Duke d'Anjou the previous year, made a Protestant succession to the throne much more likely, a second and far more revolutionary organization appeared. This second movement was centred in Paris among middle-class professional men and members of the clergy and soon spread among the Parisian artisans, guilds, and public officials. Finally, through the intervention of the Duke de Guise, it inspired the reappearance throughout the country of the old Catholic Holy League of 1576, though now in a much more extreme and threatening form. The king himself, who was considered far too tolerant toward the Huguenots, was an object of attack. In town after town, royalist officials were replaced by members of the league. In Paris, the mob was systematically aroused; in 1588, in the famous "Day of the Barricades," Henry III was driven from his own capital. After the murder of Guise at the end of that year, the league came out in open revolt against the crown. Towns renounced their royal allegiances and set up revolutionary governments. In Paris, however, where the league was most highly organized, a central committee called the Sixteen was established. It set up a Committee of Public Safety and conducted a reign of terror in a manner similar to the much more famous one during the revolution of 200 years later.

The Catholic Holy League in Paris

Paradoxically, this genuinely democratic and revolutionary element in the Holy League paved the way for the triumph of the Protestant leader Henry of Navarre, later Henry IV. The aristocratic members of the league took fright at the direction in which the extreme elements in the movement were proceeding. Their fears reached a climax in 1591, when the Sixteen arrested and executed three magistrates of the Parlement of Paris. The growing split in the ranks of the members of the league, combined with Henry's well-timed conversion to Roman Catholicism, enabled him to seize the initiative and enter Paris, almost unopposed, in 1594. But the threat to the monarchy and therefore to the whole French state had been of a new and fundamental kind, and the strong position that Henry IV achieved by the time of his death is that much more remarkable. Part of his success lay in the unwillingness of his great subjects to contemplate a social and political upheaval that would displace them as well as the king from their positions of power and prestige.

Political ideology. The religious wars also engendered a luxuriant growth of political ideas that in the end provided a strong theoretical basis for the reassertion of royal authority.

A strong element in Calvin's teaching was the importance of passive obedience to secular authority—an idea that became impossible for the Huguenots to support after the Massacre of St. Bartholomew's Day. They began instead to advocate the right to attack the king if he would not guarantee them toleration. The most important Huguenot contribution in this change was the anonymous pamphlet *Vindiciae contra tyrannos* (1579), which raised fundamental questions about the prince's power and the rights of his subjects. The pamphlet advanced the idea of a twofold contract: the first contract, between God and ruler on the one hand and the ruler and his subjects on the other, recognized the belief that the king ruled under the aegis of Divine Providence; the second contract, between the king and the people, obliged the king to govern justly and the people to obey him so long as he did so. It followed from the argument in the *Vindiciae* that subjects had the right to rebel if the prince disobeyed the laws of God or refused to govern his people justly. This twofold contract was not intended to be a license for private and personal rebellion but was interpreted as justifying the corporate opposition of whole towns and provinces.

A second element in the realm of political ideas, deeply opposed to the contractual theory of the Huguenots, was that of the Jesuit supporters of Ultramontanism. The Ultramontanists feared that a strong national monarchy would mean the subordination of the church to its authority and the diminution of papal authority. They feared the triumph of both Huguenotism and Gallicanism in France. Their most effective controversialist was the Italian prelate Robert Bellarmine, whose *Disputationes* (3 vol., published 1586–93) and *De potestate summi pontificis in rebus temporalibus* (1610) gave definite form to the theory of papal supremacy. By no means were all members of the league supporters of Bellarmine, though their extreme Catholicism made many of them sympathetic to his ideas. The definitive Gallican reply came in 1594 with Pierre Pithou's *Les Libertés de l'église gallicane,* which reiterated the basic tenets of Gallican doctrine: that the pope had no temporal authority in France and no more spiritual power than that bestowed on him by such conciliar decisions as the monarchy chose to recognize.

The Ultramontanists

The growing support for Gallican opinion was a reflection of the emergence of the Politique Party after the Massacre of St. Bartholomew's Day. In the opinion of this moderate Catholic group, toleration should be granted to the Huguenots for the sake of peace and national unity. The Politiques were the spiritual heirs of the chancellor

L'Hospital and represented an attitude of mind rather than an organized movement. Under the pressure of political events this group became convinced of the need to support a strong monarchy that could resist both Ultramontane and Huguenot excesses and the divisive influence of noble factions. They therefore increasingly identified themselves with the Gallican position. The Huguenots, too, were not slow to see the advantages for themselves of this new attitude, and the ideas of the *Vindiciae* gave way to the theory of passive obedience. The wheel had turned full circle.

Divine-right theories

With this emphasis upon passive obedience emerged the theory of the divine right of kings. The first written statement of the theory in France is contained in the works of Pierre de Belloy, especially his *De l'autorité du roi* (1588). He asserted that the monarchy was created by God and that the king was responsible to God alone. Any rebellion against the ruler, therefore, was a rebellion against the Almighty. The essential premise of the divine-right idea is that the right to command obedience cannot be bestowed by man; only God can grant such authority. God therefore chooses the king, and there can be no contractual relationship between the king and his people; to rebel even against an unjust ruler is to challenge God's choice. If the king breaks his contract with God, then he is answerable to God alone. On the wave of such ideas Henry of Navarre became king of a united France, supported by Huguenots and moderate Politique Catholics alike. The universalist doctrine of Bellarmine gave way to the national one of Pithou as the country closed ranks against Spain, the common enemy.

One other concept emerged about this time that helped to set the seal on Henry's authority: the idea of sovereignty, as expounded by Jean Bodin. In his *Six Livres de la République* (1576) Bodin argued that the political bond that made every man subject to one sovereign power overrode religious differences. Bodin provided the link divine right did not allow between the king and his people; divine right was concerned with the source of the ruler's power, sovereignty with its exercise. The needs of the political situation forced Bodin to give his sovereign virtually unlimited authority, though he insisted—as was traditionally the case in France—that the ruler should respect the sanctity of the natural law, of the fundamental laws of the kingdom, of property, and of the family. In 1614, on the occasion of the last meeting of the Estates-General before the Revolution, the Third Estate sought to have it made a fundamental law of the realm that under no pretext whatever was it permissible to disobey the king. This effort gives some indication of the extent to which the ideas of divine right and sovereignty had provided a firm theoretical base for the reestablishment of monarchical power after the dangerous years of civil war.

FRANCE IN THE EARLY 17TH CENTURY

Henry IV. The restoration of royal authority was not, of course, simply a matter of adjusting theories of kingship; there was a clear practical reason for Henry's success. The country had tottered on the brink of disintegration for three decades. By the time of Henry's succession, it was generally recognized that only a strong personality, independent of faction, could guarantee the unity of the state, even though unity meant religious toleration for the Protestant minority. By the Edict of Nantes (April 13, 1598) Henry guaranteed the Huguenots freedom of conscience and the right to practice their religion publicly in certain prescribed areas of the country. As a surety against attack, the Huguenots were granted a number of fortresses, some of them, such as La Rochelle and Montpellier, extremely formidable. Huguenots were made eligible to hold the same offices as Roman Catholics and to attend the same schools and universities. Finally, to ensure impartial justice for them, the Edict established in the Parlement of Paris—the supreme judicial court under the king—a new chamber, the Chambre de l'Édit, containing a number of Protestant magistrates who would judge all cases involving Huguenots. Although the problem of religion was not finally settled by the Edict of Nantes, Henry did succeed in effecting an extended truce during which he could apply himself to the task of restoring the royal position.

Sully's financial reforms

The chief need of the monarchy was to improve the financial situation, parlous since the days of Henry II's wars and aggravated by the subsequent internecine conflict. Henry was fortunate in this connection to have the services of Maximilien de Béthune, Duke de Sully, who was admitted to the king's financial council in 1596. Sully at once embarked upon a series of provincial tours, enforcing the repayment of royal debts, thereby increasing the king's revenues. He also provided the first real statements of government finances in many years; by 1598 he had become the effective head of the royal financial machine as well as a trusted member of the king's inner Cabinet. He held a variety of offices: superintendent of finances, grand master of artillery, superintendent of buildings, governor of the Bastille, and others. But it was in the field of finance that he made his greatest contribution to the welfare of the state. Sully was not an original financial thinker. He undertook no sweeping changes, contenting himself with making the existing system work, for example, by shifting the emphasis from direct to indirect taxation. He succeeded in building up both an annual surplus and substantial reserves.

The only measure Sully championed that might be described as novel and far-reaching was the introduction in 1604 of a new tax, the *paulette,* named after the financier Charles Paulet, which enabled officeholders to assure the heritability of their offices by paying one-sixtieth of the purchase price each year. The *paulette* was intended to increase royal revenues, though it had considerable political implications too, in effect making government offices practically hereditary. Politically, the *paulette* was to increase the independence of a wide range of royal officials, thereby limiting royal absolutism and strengthening the possibility of disinterested state service. In addition, Sully did much to reorganize fortifications and to rebuild roads and bridges after the devastation of the religious wars. In transportation his greatest work was the Briare Canal project to join the Seine and Loire rivers—the first such scheme in France—completed under Louis XIII.

Sully, however, favoured a much more cautious domestic policy overall than did his sovereign; because Sully disliked merchants and manufacturers, he opposed many of the king's economic ventures. Henry IV believed in direct state intervention, and he took steps to fix wages and to prohibit strikes and illegal combinations of workmen. Henry's policies bore fruit especially in the textile industries, where the production of luxury silk goods and woolen and linen cloth greatly increased. Henry also took the initiative in making commercial treaties with Spain and England, thereby increasing the volume of French trade and stimulating the export of grain, cattle, and wine. Yet his efforts were not entirely successful, not least because merchants were more concerned with buying land and office (and thereby status) than with plowing back their profits into further industrial development. Though the country did assume a more prosperous air under Henry IV, that change was chiefly because of the domestic and foreign calm that followed the Peace of Vervins.

Henry's foreign policy

Even after Spain's agreement in 1598 to the restoration of the territorial position as it had existed in 1559, Henry was not free of international complications. But he was able to prevent them from once more dividing his kingdom. He did have to counter a conspiracy led by one of his own marshals, Charles de Gontaut, Duke de Biron, who plotted with the king of Spain and almost succeeded in raising southwest France in revolt. Henry, however, had Biron arrested and executed in 1602; this strong action against an old friend and powerful enemy had the effect of subduing the political rising and strengthening Henry's own authority. In central government Henry gave increasing power to Sully at the expense of the rest of his council, while in the provinces the responsibilities of the intendant, an official first regularly employed during the reign of Henry III, were widened to include the supervision of potentially dissident groups. The intendants also represented the crown at meetings of provincial estates, enforced royal laws, and advised the king on a variety of local problems—fiscal, administrative, and military. When Henry IV was assassinated by François Ravaillac, a Catholic fanatic, in

May 1610, he had gone a long way toward restoring the monarchy to a position of authority similar to that held by Francis I and Henry II and had reunified a state greatly threatened at his accession from both within and without.

The rise of Richelieu

Louis XIII. Henry's reign was followed by the regency of his widow, Marie de Médicis, who ruled on behalf of their young son Louis XIII (1610–43). Once more the security of the country was threatened as factions disputed around the throne. The work of Henry IV seemed likely to be undone. Crown and country, however, were rescued by probably the greatest minister of the whole Bourbon dynasty—Armand-Jean du Plessis, Cardinal de Richelieu. Richelieu first came to the attention of the government in 1614, when he was chosen to present the final address of the clergy at the meeting of the Estates-General. His eloquence and political expertise on this occasion won him the notice of Marie de Médicis, who later appointed him her secretary. By 1616 Richelieu was secretary of state for war and foreign affairs. His career, however, received a check in the following year when a palace revolution overthrew the regency of the queen mother, exiling her to Blois. Richelieu was banished first to Luçon and subsequently to Avignon (1618). He began the climb back to power by negotiating the Treaty of Angoulême (1619), which reconciled Louis XIII to his mother. After the death in 1621 of Louis's favourite, Charles d'Albert, Duke de Luynes, Richelieu regained effective power; he became a cardinal in 1622 and in April 1624 gained access to Louis XIII's council. On the disgrace in 1624 of the superintendent of finance, Charles de La Vieuville, he became Louis's principal minister—a position which he maintained until his death some 18 years later.

Richelieu proved an indefatigable servant of the French crown, intent on securing absolute obedience to the monarchy and on raising its international prestige. The first objective required him to crush a number of revolts of the nobles, the first of which, in 1626, involved the king's younger brother and heir, Gaston de France, Duke d'Orléans. Louis acted ruthlessly, and one of the conspirators, Henri de Talleyrand, Count de Chalais, was executed. Then, in 1630, came the celebrated "Day of Dupes" when the king's life was despaired of and the queen mother, now allied with Gaston and the keeper of the seals, Michel de Marillac, prepared to move against Richelieu. The king, however, recovered and chose to support Richelieu against the wishes of his mother, his wife, and his confessor. Finally, at the very end of his life, the cardinal had to overcome another conspiracy headed by the young royal favourite, Henri Coiffier de Ruzé, Marquis de Cinq-Mars, in which Gaston was once more implicated. Through all these crises Richelieu retained the king's support, for it was in Louis's interests, too, that such intrigues should be firmly dealt with.

In the course of strengthening royal absolutism, Richelieu also came into conflict with the Huguenots. He believed that their right under the Edict of Nantes to maintain armed fortresses weakened the king's position at home and abroad. Protestant rebellions in 1625 and 1627 persuaded the cardinal of the need for a direct confrontation. The major Huguenot citadel of La Rochelle was attacked by royal troops in 1627 and, despite attempts by the English to assist the Protestants, fell in the following year. Another royal army marched into Languedoc, where the Huguenot forces were concentrated, and quickly overcame them. The Peace of Alais (1629) left the Huguenots free to enjoy religious and civil liberties, but they lost the military power that had made them a threat to the government. They were never to pose that sort of threat again, and little more would be heard of them until Louis XIV decided to repeal Henry IV's Edict of Nantes.

Richelieu also took a great interest in economic matters. To promote economic self-sufficiency, he encouraged the manufacture of tapestry, glass, silk, linen, and woolen cloth. He gave privileges to companies that established colonies in America, Africa, and the West Indies. To protect trading and colonial interests, he created a navy, which by 1642 had 63 oceangoing vessels.

Richelieu's anti-Habsburg policy

On the basis of these policies, Richelieu was able to pursue an increasingly successful foreign policy. His first aim was the security of France, which he hoped to achieve through the occupation of key points on the country's frontiers lying along imperial and Spanish territories. He thus involved France in the War of the Mantuan Succession (1628–31) in northern Italy. Through diplomatic means he worked for the dismissal of Albrecht Wenzel von Wallenstein, the brilliant general fighting on the side of the emperor Ferdinand II, whose forces were threatening to destroy the Protestant princes of Germany in the Thirty Years' War. To undermine the power of the Habsburgs, he prolonged this conflict, negotiating with the United Provinces; with Gustav II Adolf of Sweden, with whom he concluded the subsidy Treaty of Bärwalde in 1631, agreeing to pay the Swedish king one million livres per year to continue the war; with Gustav's successor, Count Axel Oxenstierna; and with Bernhard, Duke of Saxe-Weimar. Eventually, in 1635, Richelieu committed France to direct conflict with the Habsburgs; and before his death he had savoured the triumph of having French arms in the Spanish Netherlands, Lorraine, Alsace, and Roussillon.

The career of Richelieu bears something of a contradictory aspect. He undoubtedly added to the earlier success of Henry IV and Sully in overcoming the threat of anarchy and disorder that was the legacy of the late 16th century. Indeed, his contemporary reputation was one of supreme ruthlessness and arbitrariness in the application of power. Yet he was never more than the king's creature, incapable of pursuing a course of action of which Louis disapproved, always vulnerable to the loss of royal favour and support. He was ambitious, but he recognized that his desire for power could best be satisified within the confines of dutiful royal service. Richelieu was no innovator: he devised neither new administrative procedures nor novel methods of taxation to secure the king's authority. Indeed, the power of the great financiers grew with the government's need for additional war revenue, posing a different threat to royal absolutism. Richelieu's unique contribution lay in the single-minded devotion he gave to the task of increasing royal authority at home and abroad. He also succeeded in accumulating a vast personal fortune as a result of his years in power. Richelieu died in 1642, and Louis XIII died the following year. France was once again ruled by a regent, the queen mother, Anne of Austria. But the task of governing the country fell increasingly into the hands of another cardinal, Jules Mazarin.

Opposition to Mazarin

The Frondes. The years of Louis XIV's minority were dominated by the Frondes, a series of civil disturbances that lasted from 1648 to 1653. The government's financial difficulties were once more at the root of the trouble. In the first few years of the regency a variety of expedients were tried to raise additional revenue for the war with Spain. There was about these expedients an air of arbitrariness and compulsion that antagonized a wide cross section of Parisian society, notably the Parlement of Paris, and the animosity was heightened by Mazarin's use of intendants in the localities to cut across traditional legal hierarchies. Although most of the disputes were on the face of it concerned with financial exactions, below the surface an older constitutional argument was developing, as Mazarin followed Richelieu in attempting to dictate from the centre in the interests of the state. The climax came when the government failed to renew the *paulette* for the members of the provincial *parlements* and for some of the chief legal officeholders in the capital, in the Cour des Aides, the Chamber of Accounts, and the Great Council. This decision was not a gratuitous rebuff to these magistrates but yet another attempt to gain additional revenue, this time by offering a renewal of the *paulette* in lieu of four years' salary.

At this point, the first Fronde (the Fronde of the Parlement) began with the outraged magistrates of the three courts concerned joining with the Parlement of Paris to demand redress. Their demands included the abolition of the office of intendant; a reduction in the level of the taille; and the restoration of normal judicial procedure in registering financial edicts in the Parlement. The regent and Mazarin at first took a conciliatory attitude, but each side gradually moved to more committed and extreme positions, and civil disturbances in Paris exacerbated an already delicate situation. The magistrates increasingly aimed their fire at Mazarin, for he, like Richelieu before him, seemed to be taking over the king's authority and using it in uncharted and illegal areas. The magistrates, however, were not revolutionaries, and the state of disorder in the capital frightened them. That fact, allied with fears of a Spanish invasion (for the war was still continuing with Spain despite the Peace of Westphalia in 1648), persuaded them, in 1649, to make the Peace of Rueil with the government, the terms of which were for the most part favourable to the magistrates' original demands. At this stage the second civil war broke out, the Fronde of the Princes, headed by the Great Condé. The second Fronde was a pale reflection of the feudal reaction during the Wars of Religion; and, although Condé succeeded in gaining control of Paris, he did not acquire the support of the Parlement except briefly and under duress. In October 1652 Condé fled to Spain, and Louis XIV reentered his capital in triumph.

The Fronde of the Princes

Neither Fronde posed the grievous threat to the very basis of the state that had existed in the previous century. Mazarin was the chief object of enmity, and that fact itself helps to explain the less serious nature of the threat. What was at issue was not the king's authority per se but the manner in which it had been exercised since Richelieu's time, in a less personal and therefore seemingly more arbitrary fashion.

After the Frondes, Mazarin continued to play a key role in government as chief adviser to the young king, whose respect and affection he had long possessed. His career ended on a high note with a successful conclusion of the war with Spain negotiated by the Treaty of the Pyrenees (1659). According to its terms, France gained Roussillon and Cerdagne in the south and Artois and a number of border towns in the north; and the Rhine became France's frontier in the east. By the treaty, too, Louis XIV was betrothed to the infanta Marie-Thérèse, the elder daughter of Philip IV of Spain. It was by any reckoning a triumphant peace, though it sowed the seeds of future European conflict over the issue of the Spanish succession (see below). When Mazarin died in 1661, Louis was confident enough to take up the reins of government without recourse to another first minister.

The European crisis of the 17th century

Before examining the most famous reign in French history, one further aspect of the previous decades requires scrutiny—the economic and social situation to which some historians have attached considerable importance, especially as an element in the so-called general European crisis of the 17th century (a series of upheavals—among them the Frondes and the English Civil War—that affected Europe in the middle of this century). A Soviet historian, Boris Porshnev, first drew particular attention to the series of local uprisings taking place in France in the first half of the 17th century. He noted that all of them contained an element of desperation as serious financial hardship brought about by exorbitant tax demands and crop failures forced the participants into action. Great fluctuations in prices and outbreaks of famine further accentuated the misery. From these observations he drew ideological conclusions that have been widely disputed. Porshnev maintained that the state was the instrument by which the dominant economic class exploited the underprivileged and that revolt was a sign of the popular resistance of the exploited masses. On the other hand, Roland Mousnier, perhaps the greatest French authority on the period, has pointed to evidence that suggests that these revolts were not always spontaneous: they were provoked in 1632 by the municipal authorities at Lyon; in 1636 by the nobility of Périgord; and in 1641 by Louis, Count de Soissons, a prince of the blood. In 1643 the conduct of bishops and magistrates in Languedoc was seen by one royal official as likely to encourage sedition there. From these examples and others like them, Mousnier concludes that the nobility was seeking to reverse the process by which the king's officials were extending the crown's authority at their expense, taxing peasants to such a degree as to limit the amount the peasants could afford to pay in seigneurial dues, insinuating the king's justice between themselves and their peasants, reducing their prestige in the local community, and trampling upon old rights and privileges. Mousnier asserts that the nobility, far from representing the oppressive state, was itself involved in a struggle against increasing state interference. The opposition provoked by the work of Richelieu and Mazarin fits well into Mousnier's view and gives it support. It remains true, however, that most popular revolts began as protests against fiscal demands that were intolerable to people already suffering grievous economic hardship and that they were often provoked by a particular incident, such as the appearance of a new tax collector or a new system of tax collection.

There was little sign of the revolutionary attitude that had characterized aspects of the 16th-century Wars of Religion. On the contrary, there were positive indications of continuing loyalty to the crown, with such rebel slogans as "Vive le roi sans la gabelle" or "Vive le roi sans la taille." Nor was the other great bastion of the establishment, the church, attacked. The substantial tax of the tenth continued to be paid to the church without complaint. During the Frondes, neither the nobles nor the magistrates represented a revolutionary political element, and even the rioters on the Parisian streets were simply desperately poor. There was no social revolution either under Henry IV, Richelieu, or Mazarin despite the appearance of increasing numbers of hereditary officeholders, aided in their dynastic ambitions by the device of the *paulette*. The elevation to noble rank of new families was a cyclical process in France that would continue through and beyond the reign of Louis XIV.

THE AGE OF LOUIS XIV

Throughout his long reign Louis XIV (1643–1715) never lost the hold over his people he had assumed at the beginning. He worked hard to project his authority in the splendid setting of Versailles, to depict it in his arrogant motto: "Nec pluribus impar" ("None his equal"), and in his sun emblem. He buttressed his authority with the divine-right doctrines elaborated by Bishop Jacques-Bénigne Bossuet and proclaimed it across Europe by force of arms. Yet he made surprisingly few institutional or administrative changes in the structure of government. Like Richelieu, Louis used the system that he had inherited and adapted it to suit his own personality and outlook. This practice may be seen first in his attitude to the machinery of central government.

Louis's inner council

The development of central government. Louis's inner council was on the model of the royal council in Richelieu's days, a High Council (Conseil d'en Haut) consisting of only three or four members and excluding the king's own relatives. Members of this council were known as ministers, but they held no formal right to the title and ceased to be minister if the king chose not to summon them. The first of these great men were Michel Le Tellier, Hugues de Lionne, and Nicolas Fouquet; but the latter was disgraced within a year, and by 1665 his place had been taken by Mazarin's former secretary, Jean-Baptiste Colbert. These three men dominated the government in the early years of Louis's personal reign, but always, as with Richelieu and Louis XIII, under the watchful and jealous eye of the king. Le Tellier had been secretary of state for military affairs under Mazarin's regime, and his greatest contribution under Louis was to reorganize the army along lines that were hardly changed until after 1789. He created a royal army that wore the king's uniform; it was commanded by his officers and was ultimately responsible to the sovereign. It was a standing army of hitherto undreamed-of size, reaching 400,000 men in times of war and requiring close regulation in matters of discipline, training, recruitment, supply, and overall organization. The success of Le Tellier and of his son Louvois, who succeeded him, goes far to explain the dominance of French arms in Europe during Louis's reign.

Lionne, the expert in foreign affairs, had been the chief French negotiator at the Peace of the Pyrenees. His effective influence with Louis is difficult to gauge; he certainly was not the sole source of advice in foreign affairs. Lionne remains a more elusive personality than his colleagues, though there can be no doubt of his importance. It should be remembered that all important matters of state were reviewed at the High Council; and the king's ministers were expected to give advice and opinions on all that was discussed, not simply on matters in the area of their particular expertise.

Colbert's financial reforms

Colbert, however, remains the best-known of these intimate counselors. Of the 17 ministers summoned by Louis XIV to the High Council during his reign, 5 were members of the Colbert family. In 1664, Colbert was appointed superintendent of the king's buildings; in 1665, controller general of finances; in 1669, secretary of state for the navy. His capacity for work and his grasp of detail were remarkable; but he was not an original, much less a revolutionary, thinker. His chief contribution to the king's finances, like Sully's, was to make the machinery more efficient, not to substitute any new mechanisms. Colbert's first achievement was to present the king with a monthly statement of the financial situation, though his annual estimates for the following year never persuaded Louis of the need for economies if his mind was set in other directions. Yet, within 10 years of taking office, Colbert, mainly by tightening up on the tax-collecting administration and by rationalizing the gathering of indirect taxes, did succeed in producing a surplus. He turned a large part of central and northern France into a free-trade area and gave the responsibility for collecting all indirect taxes there to a new syndicate of tax farmers called the Farmers-General. Under Colbert, the total sum levied from indirect taxation rose from 36 million livres to 62 million.

In his industrial policy Colbert believed that France needed to produce for itself those manufactured goods that it was having to import. To achieve this mercantilist goal, derived from, among other sources, the ideas of Richelieu, Colbert was willing to invoke a variety of improvisations: direct subsidies, exemptions from the taille, monopoly grants, controls exercised through town guilds. Skilled foreign workmen were persuaded to settle in France and to pass on their skills to native artisans; protective tariffs were imposed. The famous tapestry works of the Gobelins family was made a state enterprise, and France became largely self-sufficient in the production of woolen cloth. Colbert also had some success in other industries, such as sugar refining, plate-glass making, and the production of silk, naval stores, and armaments. The overall results of his hard work, however, were disappointing. France underwent no industrial revolution during the reign of Louis XIV.

Growth of the navy

Much more successful were Colbert's efforts at fostering the growth of the navy. He reorganized the recruitment system on a rotary basis, whereby seamen served in the royal navy for six months in every three years. He refurbished the hospitals in each of the major ports; rebuilt the arsenals at Toulon and Rochefort; and increased the size of the navy from about 25 ships in 1661 to 144 in 1677. He also established schools of marine engineering, hydrography, and cartography. His interest in reestablishing French sea power was, in part, to challenge the commercial supremacy of the Dutch. He encouraged the building of the French mercantile marine and established a number of overseas trading companies, in particular the East India and Levant companies, neither of which had much success. He also attempted to protect French colonial interests in the West Indies and Canada.

The king's council

Besides the High Council, the king's council also met for somewhat less vital matters under a variety of different guises. The Council for Dispatches (or, more loosely, the Council for the Interior; Conseil des Dépêches) had particular responsibility for home affairs, including the activities of the intendants; the Royal Council for Finances (Conseil Royal des Finances) supervised important matters affecting financial aspects of the king's domain lands. These two councils, like the High Council, were presided over by the king in person. But the royal council also met under three further titles to deal with judicial and administrative matters and not in the king's presence. The Privy Council (Conseil Privé) judged disputes between individuals or bodies and dispensed the king's supreme and final judgments. The State Council for Finances (Conseil d'État et Finances) expedited financial matters of secondary importance, while the Financial Arbitration Court (Grande Direction des Finances) was an administrative tribunal settling disputes between the state and individuals or corporations. Each of these subdivisions of the king's council contained more members than the exclusive High Council, made up of the secretaries of state and of financial and judicial experts.

The initial group composing the High Council contributed a great deal to the basic pattern of Louis's reign, particularly in military, fiscal, naval, and commercial attitudes, partly because many of those who followed as ministers came from the same tightly knit group of royal servants. The five members of the Colbert family have been mentioned; there were also three Le Telliers; and, while only one member of the Phélypeaux family, Louis II, Count de Pontchartrain, was a minister, four served as important secretaries of state. All these counselors reflected the attitude of the king himself: they worked extremely hard; they proffered advice but were under no illusions about the danger of arguing once Louis had made up his mind; and they favoured a protectionist, paternalist policy, whether in the organization of industry, the administration of the colonies, or the building up of the navy. Only toward the end of the reign, with the establishment of the Council of Commerce in 1700, did a less regulatory policy show signs of emerging.

The intendants

To carry out the decisions reached in his intimate and secret High Council, Louis relied chiefly on his provincial intendants. Their powers were completely undifferentiated, and their commissions varied according to changes in royal policy. Like the ministers at the centre, they depended upon the king for their security of tenure. In the provinces they could exercise powers of police; raise military forces; regulate industrial, commercial, and agricultural matters; enforce censorship; administer the financial affairs of various communities; assign and collect taxes; and wield considerable judicial authority in civil and criminal affairs. Inevitably, these agents of the central government created considerable friction and hostility. These new men, with no local roots, answerable only to the king and acting almost invariably in an authoritarian context, were deeply resented by older royal officials, by municipal authorities and guilds, and by local *parlements* and estates—all of whom operated through well-established channels and according to traditional local privileges. The use of intendants, who held neither venal nor hereditary office, was one way in which the limiting effect of the sale of office on royal policies could be circumvented. The authoritarian element of Louis XIV's reign is undeniable: he was determined that no institution or social class would escape the supervision of the crown and its ministers. Thus the power of patronage, which had been exercised for generations in provincial noble households, began to lose its political significance as the king's ministers built up their own alternative administrative clienteles.

In particular, because the Frondes had remained a painful memory from his childhood, the king never allowed the great nobles a similar opportunity for revolt. Versailles became a place of surveillance for pensioned noblemen and their families whose only serious occupation was the traditional one of arms, for the pursuit of which Louis provided ample opportunities. The second rebellious group in the Frondes, the members of the Parlement of Paris, were likewise subjected to stringent controls. In 1673 Louis produced regulations stipulating that the court's remonstrances against royal enactments sent to it could in future only be made after the laws concerned had been registered. By this device the king effectively muzzled the magistrates' criticisms of royal policy. It was equally his intention to overcome the delaying tactics of the provincial courts, especially those situated close to vulnerable frontiers.

Louis's religious policy. Louis was also on his guard against religious dissent. Like most of his contemporaries, he believed that toleration had no virtue and that unity in the state was extremely difficult to maintain where two or more churches were tolerated. Consequently, especially after 1678, Louis intensified the persecution of Protestants; churches were destroyed, certain professions were put out of reach of the Huguenots, and Protestant children were taken away from their parents and brought up as Roman

Revocation of the Edict of Nantes

Catholics. The notorious practice of dragonnades, the billeting of soldiers on Protestant families with permission to behave as brutally as they wished, was introduced. Finally, in 1685 the Edict of Nantes was revoked in order that Louis could claim that he had succeeded where Emperor Leopold I had failed—that is, in extirpating Protestantism from his realm.

The revocation of the Edict of Nantes angered Protestant Europe at a time when Louis's European designs were beginning to meet serious resistance. The revocation deprived France of a number of gifted craftsmen, sailors, and soldiers. At least 600 officers, including Marshal Friedrich, Count von Schomberg, and Henri de Massue, Marquis de Ruvigny (later the Earl of Galway), joined William of Orange, the leader of the Grand Alliance against Louis. Research, however, has reversed the earlier view that the decay of French industry at the end of Louis's reign was the direct result of the expulsion of Huguenot mercantile talent.

The same zeal for uniformity made Louis attack the Jansenists. The theological position of the Jansenists is difficult to define; but Louis, who was no theologian, was content with the simple fact that these zealous Catholics had taken up an unorthodox position that threatened the unity of the state. The movement had begun over the perennial issue of grace and free will as it was propounded in the *Augustinus* of Bishop Cornelius Otto Jansen, published in 1640. In 1653 Pope Innocent X condemned five propositions from Jansen's doctrine, but the movement grew in strength with notable adherents, including Jean-François-Paul de Gondi, Cardinal de Retz, and the great mathematician Blaise Pascal. In 1705 Pope Clement XI published the bull *Vineam Domini,* which further condemned the writings of Jansen; but the archbishop of Paris, Louis-Antoine Cardinal de Noailles, appeared ready to lead the Jansenist forces in opposition to the pope. Under the influence of his confessor, Père Michel Le Tellier, Louis decided to ask the pope for another formal condemnation of the creed. Finally, in 1713, the famous bull *Unigenitus* was promulgated, which, far from ending Jansenism, drove it in the following reign into a disruptive alliance with Gallicanism. Louis's real attitude in this situation is not entirely clear: certainly his policy was in keeping with his authoritarian insistence upon unity. He was suspicious of religious innovation, and his action was consistent with the increasingly orthodox and rigid mood of his last years. Yet, in seeking the pope's support in this matter, he was reversing years of bitter hostility toward Rome when, like many of his predecessors, including Francis I and Henry IV, he had leaned heavily upon the traditional Gallican doctrine.

According to that doctrine, the French king possessed the right of temporal and spiritual regale—that is, the right to nominate new bishops and to administer and draw the revenue from bishoprics while they remained vacant. In 1673 Louis extended this right to the whole of the French kingdom, which had been enlarged in the recent War of Devolution (see below), despite papal opposition. Eventually, in 1682, the Gallican Articles were published as a law of the French state, asserting that the king was in no way subject to the pope in temporal matters and could not be excommunicated and reaffirming the independence of the French church from Rome. The mutual animosity of king and pope only ended in 1693, when, following William of Orange's successful attempt to secure the English throne, Louis agreed to suspend the edict of 1682; but it was a suspension only, not a recantation. The tradition of Gallican independence remained.

Absolutism of Louis. Thus, in religious matters (except where Jansenism was concerned), in his dealings with the nobility and the Parlement, in his attitude to the economy, and in his manner of governing the country, Louis revealed a desire to exercise a paternal control of affairs that might suggest a modern dictator rather than a 17th-century king. Though such a comparison has been made, it is most misleading; neither in theoretical nor in practical terms could Louis XIV be thought of as all-powerful. First of all, the legitimacy of his position under the law—the ancient fundamental law of succession—made him the interpreter of the law and the fount of justice in the state, not a capricious autocrat. Similarly, his kingship bestowed upon him a quasi-spiritual role, symbolized by his consecration with holy oil at his coronation, which obliged him to govern justly in accordance with the laws of God and Christian morality. He was also bound by the need to take counsel; and though he always made up his own mind, he insisted on receiving advice on all important matters of state, which further restricted any arbitrary instincts. Next, there was the essentially federal nature of the country with its collection of such peripheral provinces as Brittany, Normandy, and Provence, all retaining their own Estates and customs. Within both these *pays d'état* and *pays d'élection* (where the Estates no longer met) there was a variety of groups and corporations, not to mention individuals, with their own legally held rights, privileges, and exemptions, such as the nobility, the clergy, the towns, and the king's officers. To impose rigid uniformity in such a situation was both impossible and undreamed of by contemporaries. On the contrary, one of the king's prime obligations was to uphold and respect the myriad different rights to which his subjects laid claim.

Limitation of Louis's power

Louis's financial restraints

Perhaps most of all the king was limited by financial stringency. Louis could and often did try to persuade the cities and provincial Estates to raise their contributions and the clergy to increase the size of their *don gratuit* ("free gift"); he also created more offices and annuities. But these were mere palliatives, and the king was forced on two occasions to introduce novel measures: in 1695 he levied a capitation, or head tax, applicable to all French laymen, even to the princes of the blood; and in 1710 a *dixième* (tenth) that similarly went against the interests of the privileged classes, including the clergy, by requiring a tenth to be paid to the state from all incomes. Significantly, however, Louis made it perfectly clear on both occasions that he recognized the extraordinary and temporary nature of these impositions, made necessary by the pressures of war. It was impossible to be a despot while financial resources were so precarious. The notion persisted that the king should ordinarily live off his own domain. It was also impossible while no nationwide police force existed and while the state of communications remained so poor. All these factors make it clear that a situation simply did not exist in which totalitarian government, at least by 20th-century standards, could have had any meaning.

Finally, Louis XIV remained the prisoner of France's social structure. It is sometimes alleged that the king ruled through the bourgeoisie. It is true that a number of the most distinguished families of the reign were not of ancient nobility, but their faithful and effective service to the king was rewarded in an entirely traditional way—by social elevation. Colbert's father was an unsuccessful merchant, but all his granddaughters married dukes. In other words, the opportunity to enter the highest ranks of the nobility, which had long been available in France, was simply emphasized by Louis XIV. As the greatest nobleman in France, he had no doubt that he must retain the prestige and privileges of the nobility; but he knew equally well that the nobility should not become a caste closed to ambitious and able men. He thus maintained the tradition of royal patronage, which helped to defuse social conflict.

Foreign affairs. From the beginning of his reign Louis pursued a vigorous foreign policy. Historical opinion has traditionally held that Louis sought to dominate Europe, only to meet his just deserts at the end of his reign. More recently another interpretation has emerged, which argues that Louis pursued consistent and for the most part moderate aims and pursued them successfully up to and including the Treaty of Utrecht (1713). (For the traditional interpretation, see the article GERMANY: *The age of Louis XIV.*)

The starting point for the more recent interpretation is the ambiguous Peace of Münster (1648), forming part of the great European settlement of Westphalia, the terms of which subsequently became a bone of contention between Bourbon and Habsburg rulers. One of the critical issues of the treaty was the fate of the three bishoprics of Metz, Toul, and Verdun on the northeast frontier of France. These bishoprics, occupied by the French since 1552, were formally acquired in 1648 together with a number of towns in nearby Alsace. One of the main Habsburg aims in the War of the League of Augsburg, or War of the Grand Alliance (1689–97), and in the War of the Spanish Succession (1701–14) was the restoration of the three bishoprics and the province of Franche-Comté, also on the eastern frontier of France, connecting Burgundy with Alsace, which Louis had acquired at the Treaties of Nijmegen (1678–79) at the end of the Dutch War (1672–78). Louis, however, was determined to hold onto the gains in Alsace, however ambiguously acquired; he also hoped to add Lorraine, to the north of Franche-Comté, to further consolidate this least secure French frontier area. Lorraine was periodically occupied by French troops, notably between 1633 and 1648 and between 1670 and 1697, and Louis sought through various exchange schemes to incorporate the territory into France. The French share of the Partition Treaties (1698, 1700) in Italy was intended as an exchange for Lorraine and not as a means of threatening English and Dutch trade with the Levant. Lorraine, however, did not become a part of France until 1766.

Louis's policy in the northeast was constant and understandable. Franche-Comté was one entry into France previously exploited by its enemies that Louis succeeded in closing in 1678. He had already closed another, the port of Dunkirk, by purchasing it from Charles II of England in 1662; a third gateway, from the southern Netherlands, was effectively barred by the military fortifications erected by his great military engineer, Sébastien Le Prestre de Vauban, in the 1680s. The capture of Lorraine would have bolted yet one more dangerous entry. Of course the situation looked quite different from the Habsburg point of view, especially after Louis's seizure of the key city of Strassburg (French: Strasbourg) in 1681, an episode that goes to the heart of the controversial matter of his reunion policy. Following the successful Peace of Nijmegen, Louis began to employ his own judicial courts to claim sovereignty over all the dependencies of territories that he already possessed in Alsace, Franche-Comté, Metz, Toul, and Verdun. The maneuver enabled him to consolidate his control, especially over Alsace and Franche-Comté, though the legality of the claims to some of the alleged "dependencies" was extremely dubious. There was no legal justification whatever for Louis's greatest coup in the area—the seizure in September 1681 of the independent city of Strassburg. To Louis this key city, the door through which imperial armies could pass (and three times in the recently concluded war had passed) into Alsace, represented a serious threat, for Strassburg was within easy reach of the Danube valley and Vienna. His fears in this area may best be illustrated by his offer during the War of the League of Augsburg to waive his claim to the Spanish succession on condition that Nijmegen be respected; that Lorraine be absorbed into France (with proper compensations elsewhere); and that the Spanish and Austrian lands should not be united under one ruler. The Holy Roman

Seizure of Strassburg

French expansion, 1600–1766.

emperor Leopold I immediately rejected these proposals. When the final climactic conflict of the reign, the War of the Spanish Succession, was proceeding so badly, Louis offered to relinquish all the gains he had made from the Spanish inheritance; but he desperately hoped to hold on to Metz, Toul, Verdun, Alsace, and Franche-Comté.

The Dutch War

Louis's attitude toward the Dutch was less moderate and more bullying. His invasion of the Spanish Netherlands in 1667 and the ensuing War of Devolution frightened the Dutch into a Triple Alliance with England and Sweden, which led to the Treaty of Aix-la-Chapelle (1668). Then, in the Dutch War that followed shortly afterward (1672–78), Louis intended to warn the Dutch that France was a serious commercial competitor and to force the Dutch to give him a free hand in the Spanish Netherlands when the issue of the Spanish succession came to the fore. He learned from that war that he could never hope to incorporate a large part of the Netherlands into France against Dutch opposition; but he also continued to fear the manner in which the Dutch might try to influence the government of the Spanish Netherlands for their own economic benefit. Here again was an example of mutual hostility and suspicion in which interpretations of motives in Versailles and in The Hague were diametrically opposed. At the Treaty of Rijswijk (1697) the Dutch gained the right to keep a series of Dutch barrier fortresses within the southern Netherlands as a check against French aggression; it was Louis's seizure of these fortresses in 1701 that precipitated the War of the Spanish Succession (1701–14).

That war has usually been depicted as the most significant element in an assessment of Louis's total foreign policy: for some historians, all his relations with the rest of Europe were geared to this great issue; for others, it was the final misjudgment born of overconfidence, provoked by his own ambitious miscalculations, and destined to ruin France. It is certainly true that the approaching end of the direct ruling line in Spain had interested European rulers for many years, and the Bourbon claim to a share in that rich inheritance—deriving from Louis's marriage to Marie-Thérèse, elder daughter of King Philip IV of Spain—was accepted as a key factor in the situation. In 1668 Louis and Emperor Leopold I had gone so far as to sign a partition treaty, more than 30 years before the death of the last Spanish Habsburg, Charles II. No European statesman was surprised, therefore, at Louis's later concern when, after the signature of the Treaty of Rijswijk in 1697, he undertook negotiations with the English king William III out of which two further partition treaties emerged. The crucial moment came when Charles II's last will was published, offering the Spanish crown, in opposition to the second Partition Treaty, to Louis's grandson Philip, Duke d'Anjou (later Philip V). Louis's decision to accept did not in itself provoke war. (There is evidence, however, that both William and the Dutch believed that Charles's will would name the Habsburg candidate, and they certainly had no intention, in the light of what it did contain, of trying to force the emperor to accept a treaty whose provisions he had always resolutely opposed.) Besides, if Louis had snubbed the Spanish offer, it would have been made to Austria, and the spectre of the restoration of Charles V's empire—probably coupled with French losses on the northeastern frontiers—was intolerable. In addition, Louis had recently made peace after the War of the Grand Alliance, the hardest conflict in which he had so far been engaged, and thus had no illusions about the difficulty of overcoming another coalition under William III's leadership. One may conclude that he did not seek war. But he did make decisions that made war likely, including his recognition of the Old Pretender as James III of England, his unexplained decision to protect his grandson's right to the French throne (he was envisaging not a single, united realm of France and Spain but two Bourbon kingdoms, with the senior heir succeeding in France), his occupation of the barrier fortresses, and his seizure of the monopoly of the Spanish-American trade.

Treaty of Utrecht

When peace was signed at Utrecht in 1713, Louis, despite the disasters of the intervening years, succeeded in holding onto the gains in Europe that he had considered vital throughout his reign, including Alsace and Strasbourg. In addition, his grandson remained king of Spain, despite all of the efforts of the Grand Alliance to replace him by their candidate, the Austrian archduke Charles (as Charles III). It is true that in the darkest time of the war, during the years 1708–10, the desperate king was ready to give up these precious gains and was prevented only by the intransigence of his opponents with their impossible demand that he should himself assist in driving his grandson from the throne of Spain. Likewise, a fortuitous change of government in England in 1710, which ushered in the Tory peace ministry, and the elevation of the Austrian archduke to the imperial title as Charles VI in 1711 weakened the unity of purpose of the Grand Alliance and enabled Louis's most effective soldier, Claude-Louis-Hector, Duke de Villars, to stage a military revival. Therefore, the relatively successful conclusion of the war from France's point of view was not entirely of Louis's own fashioning. Had events forced Louis to accept a total surrender, it would have been even more tempting for historians to blame the defeat upon the excessive ambitions of an arrogant man.

It cannot be denied that Louis was arrogant and that his arrogance aroused fear and resentment in his neighbours. Equally, he was intolerant, like most of his contemporaries, and feared by Protestant powers as the leader of a new and vengeful Counter-Reformation, an irony in view of his secret encouragement of the Turks in order to weaken the emperor. Both facets of the great king need to be borne in mind when assessing his overall foreign policy, and they help to counter any tendency to overestimate the defensive nature of his strategy. That defensive element, however, is of significance and has been largely lost sight of, especially in assessments of the reign written in English. Louis frightened Europe with his quest for *la gloire,* by which he meant the favourable verdict of history on his contribution to French security and territorial integrity but which his enemies interpreted more narrowly as a preoccupation with military triumphs and vainglorious display. That contemporary interpretation, still widely accepted nearly three centuries later, does less than justice to Louis's shrewd appreciation of political realities and of France's long-term interests.

FRENCH CULTURE IN THE 17TH CENTURY

If historians are not yet agreed on the political motives of Louis XIV, they all accept, however, the cultural and artistic significance of the epoch over which he and his two 17th-century predecessors reigned. In their different ways—Henry IV's interest lay in town planning, Louis XIII's in music, and Louis XIV's in the theatre and in landscape gardening—they all actively stimulated the emergence of great talents and were aided by such royal ministers as Richelieu and Mazarin, who were considered patrons in their own right.

The rebuilding of Paris

From Henry IV's reign dates the rebuilding of Paris as a tasteful, ordered city, with the extensions to the Louvre and the building of the Pont Neuf and the Place Dauphine and, outside the capital, the renovations and extensions at Fontainebleau and Saint-Germain-en-Laye. Henry succeeded in making Paris what it had never been before—the centre of polite society—and he must therefore take some credit, though he was not personally interested in such matters, for the establishment of the famous salon of Catherine de Vivonne, Marquise de Rambouillet, which flourished from 1617 until 1665. There, men of letters mingled with the great nobility to the mutual advantage of both. The guests at her salon included the statesmen Richelieu and the Great Condé; the epigrammatist the Duke de La Rochefoucauld; the letter writer Marie de Rabutin-Chantal, Marquise de Sévigné; the novelist Madeleine de Scudéry; the poet François de Malherbe; and the dramatist Pierre Corneille.

Richelieu also was a key figure in the artistic and architectural development of Paris during his years in power. He was fortunate to employ the great architect Jacques Le Mercier, who built for him, close to the Louvre, the Palais-Cardinal, later the Palais-Royal; it contained two theatres and a gallery for the cardinal's objets d'art. Under the same patron, Le Mercier also built the church of the Sorbonne, where Richelieu is buried. In the world of painting, the cardinal supported Simon Vouet, who decorated the Palais-Cardinal, and Philippe de Champaigne, whose surviving portraits include famous representations of Richelieu himself. The cardinal's most notable contribution, however, was in the field of letters, with the establishment in 1634 of the Académie Française to regulate and maintain the standards of the French language. One of its first tasks was the production of a standard dictionary, a massive work published in four volumes in 1694. The Académie succeeded over the years in making the pursuit of letters socially acceptable, though still inferior to the pursuit of arms. Finally, Richelieu's great interest in the theatre persuaded him to patronize a number of dramatists, including Jean de Rotrou and Pierre Corneille. Richelieu's patronage of the arts was taken over by his great pupil Mazarin, who collected some 500 paintings. He housed them in the Palais Mazarin (now the National Library), which itself was enlarged for Mazarin by the architect François Mansart. He also commissioned Louis Le Vau to rebuild part of the medieval castle of Vincennes, thus setting him off on his successful career.

Versailles

Louis XIV's patronage centred on Versailles, the great palace that also played such an important part in the political life of 17th-century France. There André Le Nôtre designed the formal gardens, which still attract a multitude of admiring visitors, as they did when they were first completed. There Jules Hardouin-Mansart added the long, familiar garden facade, and Charles Le Brun decorated the Gallery of Mirrors and the adjoining rooms of war and peace with unforgettable magnificence. There the composer Jean-Baptiste Lully devised and directed a number of musical entertainments with such success that Louis granted him noble status and the office of a royal secretary. There, too, the comic genius Molière was encouraged by the king's support; after the dramatist's death Louis was directly responsible for the establishment, in 1680, of the Comédie Française. There, finally, Louis recognized the genius of Jean Racine, whose great tragedies, from *Bérénice* (1670) to *Iphigénie* (1675), earned him membership in the Académie Française and a noble office, that of *trésorier de France,* from the King.

This blossoming of the arts was aided though not inspired by the patronage of kings and ministers. The artistic creations evince a strong element of order and simplicity culminating in the classical grandeur of Racine's plays and the facade of Versailles. Thus they might seem to reflect the growth of political stability and order over which Louis XIV presided. It is, however, dangerous to tie creative achievements in the arts and sciences too closely to their political environment. Moreover, there are significant counterpoints to the theme of classical order. The philosopher René Descartes's doubting, rationalistic approach to the fundamental questions of God's existence and man's relationship to God undermined the rigid adherence to revealed truths propounded by Bishop Bossuet. The Jansenist Blaise Pascal, one of the most versatile geniuses of the century, represented and defended a minority religious movement that Louis XIV believed dangerously subversive. Toward the end of his long reign, Louis encountered the fierce social criticism of Jean de La Bruyère and the skepticism of Pierre Bayle. These discordant elements draw attention to the fact that the absolute state which Versailles was intended to represent concealed tensions that would surface after the king's death. Nonetheless, the splendour of Versailles and the classical simplicity of Racine's tragedies represent a high point in creative human achievement, and it is to his credit that the king chose to be identified with them. (J.H.Sh.)

France, 1715–89

The year 1789 is the great dividing line in the history of modern France. The fall of the Bastille, the French state prison, on July 14, 1789, symbolizes for that nation, as well as for all other nations, the end of the premodern era characterized by an organicist and religiously sanctioned traditionalism. With the French Revolution began the institutionalization of secularized individualism in both social life and politics; individualism and rationality found expression in parliamentary government and written constitutionalism. Obviously, the English and American revolutions of 1688 and 1776 prefigure these changes, but it was the more universalist French Revolution that placed individualism and rationality squarely at the centre of human concerns.

Because the revolutionary events had such earthshaking power, the history of France in the century preceding 1789 has until recently been seen as a long and quickening introduction, as a period marked by the decay of the *ancien régime* ("old regime"), a locution that came into its own during the Revolution. Some contemporary historians, however, reject this view and present 18th-century France as a society undergoing rapid but manageable change, especially in cultural concerns. They perceive the French Revolution as a political event that could have been avoided if the French monarchy had been more consistent in its effort to modify political institutions in order to keep up with social and especially cultural change.

THE SOCIAL AND POLITICAL HERITAGE

The social order of the ancien régime. To understand the developments of the 18th century and to follow the scholarly debates, one may begin with a definition of the ancien régime. Its essence lay in the interweaving of the state's social, political, and economic forms; the term itself, though primarily a political concept, has also always had a clear and social and economic resonance.

Nature of the ancien régime

In the society of the ancien régime all men and women were by birth subjects of the king of France as well as members of an estate and province. In theory always and in practice often, the lives of French men and women of all ranks and estates took shape within a number of overlapping institutions, each with rules that entitled its members to enjoy particular privileges (a term derived from the Latin words for "private law"). Rights and status flowed as a rule from the corps to the individual rather than from individuals to the group, as was true after 1789.

France itself can be conceived of as an aggregate of differentiated groups or communities (villages, parishes, or guilds), all of them theoretically comparable, but all of them different. In many respects the kingdom was an assembly of varying provinces, a number of them endowed with vestigial representative institutions. In some important ways France was not truly a unit of government. Unlike England, for example, France was not a single customs union; more tariffs had to be paid by shippers on brandy floated down the Garonne to Bordeaux than on wine shipped from France to Britain.

The concept of national citizenship was not unknown in France under the ancien régime, existing in the sense that all Frenchmen, regardless of their rank and privileges, had certain legal rights denied to all foreigners. There was, however, no French nation whose citizens taken one by one were equal before man-made law, as was true after 1789. Laws were in the main inherited, not made. This is not to say that France, though structured around the "premodern" concept of the guild, or group, or *corps,* was a static or, materially speaking, a stable society. For many artisans, peregrination was a way of life, and many years of their young manhood were spent on a *tour de France,* which took them from city to city in order to learn their trade. Serfdom was practically unknown (only 140,000 serfs remained in France in 1789, and none of them on crown lands, where Jacques Necker, the comptroller general, had abolished serfdom in 1779), and peasants were free to move as they wished from one village to the next. Indeed, such large numbers of people were moving around that the fear of unattached vagrants was strong in prerevolutionary France.

Monarchy and church. In the 18th century the king still thought of himself as the feudal suzerain of his subjects. Familial imagery was an important component of royal rhetoric; the king of France was father of his subjects. His right to reign echoed all husbands' right to rule over their wives and all fathers' right to rule over their children. His messages, however draconian and confiscatory they might be, were invariably couched in a rhetoric of religious and paternal solicitude.

King and church

The king, moreover, was a Christian monarch and as such was endowed with quasi-priestly functions. He was anointed at his coronation with holy chrism said to have been brought from heaven by a dove. It was thought that as evidence of his special status he could cure scrofula by his touch. The relationship of church and state was complex. Oftentimes the king did not hesitate to exploit the church, over which he held extensive power by virtue of the still-valid Concordat of Bologna of 1516. Monarchs used their right to appoint bishops and abbots to secure the loyalty of impoverished or ambitious nobles. The king could also extract whatever moneys he wished from the church taken as a whole, and schemes of wholesale confiscation were bruited from time to time. Some monasteries were reformed or consolidated by the crown.

Nonetheless, until 1788 the Roman Catholic church retained in France unusually broad doctrinal rights and social prestige, even by the standards prevailing in central or southern Europe, not to speak of what held true in the far more tolerant countries of northern Europe (Prussia, Holland, and Britain). French Protestants were denied religious toleration until 1787. Jews were only tolerated as quasi-foreigners until 1791. Of considerable symbolic importance was the fact that before 1789 it was the church that kept the registers of births and deaths which marked the beginning and end of each person's earthly existence. The church, the police, and the courts collaborated closely to maintain the prestige of religion; until at least the 1780s the church severely condemned licentious or irreligious books such as Rousseau's *Émile*, which was burned in 1762 by order of the Parlement of Paris (as it also was, incidentally, in Geneva, and in Rome by order of the pope).

The monarchy basically respected the various rights of the church accrued by tradition, as it did the civil and property rights, or "liberties," of its subjects generally. Continuity ordinarily seemed to be the first principle of the French state, and it was inherent in the concept of king itself: the king was held to have two bodies, a physical one, which necessarily decayed, and a spiritual one, which never died. The main purpose of the French state was to defend vested interests—*i.e.*, to maintain continuity rather than to change the existing order.

Commitment to modernization. The great peculiarity of the ancien régime, however, was that traditionalism, though deeply felt, was only one-half of a complicated institutional diptych. When first conceived by Cardinal Richelieu between 1624 and 1642 and developed after him by Mazarin, Colbert, Louvois, and the Sun King, the ancien régime was also committed to a program of modernization. Guided by a modern *raison d'état*, the state was eager to further changes of all kinds. Administratively, its absolutist will, formulated at Versailles in a complex array of governmental councils, was enforced in the provinces by the intendants and their subordinates. The monarchy also protected modern manufacturing and, more desultorily, modern finance. It protected and firmly guided intellectuals through the Académie Française founded in 1635. With greater hesitation the monarchy also staged France's drive to economic and military supremacy not just in Europe but overseas as well, in Canada, India, Africa, and the Caribbean.

Divided in its goals, some of them traditional and others modern, the state was also ideologically double-minded. In the 17th century many intellectuals (some of them clerics like Bishop Jacques Bénigne Bossuet [1627–1704]) developed a Hobbesian justification of absolutist rule, which was renewed throughout the 18th century. Religion and tradition went hand in hand, but absolutist theoreticians went further. They justified the state's right not only to legislate and tax more or less at will but also to imprison arbitrarily without due process of law. The lettres de cachet, which allowed the king to have individuals committed to the Bastille and to other prisons forever and without any kind of trial, were seldom given out, and usually to fathers who wished to correct their wayward children. But they did exist, as liberal or scurrilous propagandists knew full well, sometimes at first hand: about one-fourth of the 5,279 people imprisoned in the Bastille between 1660 and 1790 were connected with the world of the book.

Lettres de cachet

CONTINUITY AND CHANGE

The political history of 18th-century France can be conceptualized in terms of the double heritage and the problems it entailed. The discussion may be linked to two issues: first, the economic transformation of a traditional and essentially agricultural society by both commerce and ideas; and, second, the state's efforts (and eventual inability) to modernize and unify its structure and purpose in order to encompass the changed economic and cultural expectations of the nation's elites.

Economic change in 18th-century France was not uniform. Some of it was of a familiar and recurrent kind, such as increases in population and food shortages, and new and unfamiliar kinds of transformations created by economic and cultural developments. Whereas the first kind of change primarily affected rural France, the second kind was more pronounced in urban France, especially in the north and west, where economic and cultural developments had created a population that longed, often unconsciously, for the deep-seated political upheaval that eventually occurred in 1789.

Comparison with England

Agricultural patterns. In its basic organization, French agriculture continued in its age-old patterns. This contrasted starkly with England, where new agricultural techniques as well as major changes in the control of land—convertible husbandry (a progressive form of land use that did away with the wasteful fallowing of land every two or three years) and the enclosure movement (which made possible the consolidation of small parcels of land into large farms fenced off from use by the rest of the community)—had caused an agricultural revolution. In France there was no significant enclosure movement, despite enabling legislation that allowed the division of some common lands in 1767 and again in 1773. But ordinarily held plots were not divided, and communal patterns of planting—very common in northern France, where a three-field system ordinarily prevailed—were not suspended. Though leaseholding tended to become more frequent, most peasants were sharecroppers, especially in southern France (where a two-field system prevailed). Capitalism did not become a basic trait of rural life; peasants neither produced for the market nor diversified their crops. Their primary goal was not to become richer by taking advantage of economic opportunity but to keep their family afloat by growing enough grain.

Peasants. The condition of many peasants deteriorated markedly in the 18th century; perhaps as many as one-third of them were sporadically indigent. This cannot be explained by a decline in the peasants' share of the land. In 1789, French peasants still owned about one-third of arable land, most of it in small plots of less than 10 acres (nobles owned about one-fifth of the land, the church one-sixth, and bourgeois landlords about one-third as well). In the first half of the century, overall yields may even have risen imperceptibly, and in some years between 1780 and the Revolution perhaps by as much as 1 percent. But the peasant population itself grew more quickly than did agricultural production; thus the per capita production did not change very much and may even have declined. Most contemporaries, including Voltaire, underestimated the population expansion, but it is now known to have been considerable. Fears of scarcity and even starvation were ever present.

Population growth

Demographic changes. Rates of demographic growth varied greatly from place to place: in Brittany, where typhoid fever was endemic, population figures peaked in 1700. In Quercy they grew by 70 percent between 1700 and 1786. But, regardless of local variations, France as a whole counted two million more peasants in 1790 than during the reign of Louis XIV. Better preventive medicine, a decline in infant mortality, and the near disappearance of widespread famine after 1709 all served to increase the size of the population. Birth rates continued to be very high, despite both a traditional pattern of late marriage (men on the average at 27, women at 24 or 25) and the beginnings of the practice of birth control, whose effect was to become evident only after the Revolution. The yearly number of deaths per 10,000 fell from about 400 in 1750 to 350 in 1775, 328 in 1790, and 298 in 1800. In consequence, the average life expectancy of peasants rose from 21 to 27 years (although many individuals, of course, lived longer). Because emigration either to the cities or abroad was slight, the number of rural wage earners grew and did so at a time when prices rose, which they did by more than 60 percent between 1726 and 1789. Material hardship was certainly in 1789 a critical factor behind the deep malaise of the peasantry. Politically, this rural sense of unease mattered a great deal because it made it impossible for the monarchy to rely on the countryside in order to crush urban dissent, as was to happen in central Europe during the Revolutions of 1848.

Rural travails were nothing new; population growth had also been a grievous problem in the 15th and 17th centuries. Still, while significant in themselves, they were all the more troublesome because of other changes concurrently affecting France.

Industrial production. After 1740 overall production in France rose annually by about 2 percent, and even more in some sectors. During the later decades of the 18th century, French industrial production grew rapidly, although not on the same scale as in Britain, whose industrial development had begun 60 years before that of the French. Coal mining was a major industry by 1789, its production being nearly 6 percent higher in the 1780s than in the preceding decade. Mining attracted vast amounts of capital, some of it from the aristocracy. In 1789 the Mines d'Anzin near the Belgian border already employed thousands of workers. In textiles, entrepreneurs like the Swiss Protestant Guillaume-Philippe Oberkampf created new manufactories that permitted better regulation and control of production.

Although France on the eve of the Revolution was not yet a unified national market (as Britain had long since been), largely because internal customs were only abolished after 1789, price discrepancies from province to province, as well as between northern and southern France, were less significant than before. Throughout the country the demand rose for urban manufactured goods and for those luxury items (textiles, porcelains, furniture, *articles de Paris*) in the production of which the French excelled before 1800.

Industrial development

French industrial development was not hindered by the archaic institutional shape of the ancien régime. In 1789 France was only a generation behind England. Although French coal production was not much more than one-tenth that of Britain, the overall rate of French industrial growth in the 18th century was high. Steam-driven pumps, most of them imported from England, were already used in mines and also in Paris, where they served to pump water up from the Seine. French engineers and artisans were highly skilled. French ship design, for example, was superior to that of the English, who routinely copied captured French men-of-war. George Washington, wishing to buy the best watch available anywhere, turned to the American minister in Paris because the world's most accurate timepieces were still made in France.

Commerce. Commerce, especially with the colonies, was an important area of change as well. France's first colonial empire, essentially located in America, was a source of great wealth. Even though France lost both Canada and India during the Seven Years' War (1756–63), the Caribbean sugar islands continued to be the most lucrative source of French colonial activity in the last 100 years of the ancien régime. The French shared the West Indies with Spain and England: Cuba, Puerto Rico, and the western half of Hispaniola belonged to Spain, Jamaica to England; but Guadeloupe, Martinique, and Saint-Domingue (Haiti)—the richest of all nonwhite 18th-century colonies in the world—were French. There 20,000 whites stood an uneasy watch over 160,000 black slaves, imported from Africa, where they had been purchased from black slave merchants who were paid with arms, baubles, and drink. In the islands, the slaves produced sugarcane and coffee, which were refined in France at Nantes, Rochefort, and Bordeaux and often reexported to central and northern Europe. This triangular trade grew 10-fold between 1715 and 1789, and the value of international exports in the 1780s amounted to nearly one-fourth of national income. The sugar trade enriched the planters, the bankers in Paris who had acted as brokers for import and reexport, and the manufacturers of luxury goods that were shipped from France to the Caribbean; the French colonial trade was a closely watched process, governed by mercantilist protective tariffs and rules.

Colonial trade

In the last two decades of the ancien régime the colonial trade lost some of its appeal. Greater profits could then be made in China, India, and East Africa. When the monopoly position of the state-controlled French East India Company ended in 1769, commerce with East Asia was more than doubled. But the West Indies trade remained the single most important aspect of French commercial life in the 18th century. Hence the fact that many of the leading participants of the Revolutionary drama, including the Lameth brothers who dominated the National Assembly in 1791, had connections with the islands. Hence also the appearance of an antislavery movement on the eve of the Revolution. The essayist Charles-Louis de Secondat, Baron de Montesquieu, had already criticized the barbarism of slavery, and in 1788 the Société des Amis des Noirs (Society of the Friends of the Blacks) was founded in Paris and counted among its members not only the Marquis de Lafayette but also Jacques-Pierre Brissot, who later became the leading figure of the Girondin faction, which dominated the Revolutionary government in 1791–92.

Gradually the immoral aspects of trade in the colonies became inescapable, but its first impact was a betterment of economic conditions in France. Obviously, only a few individuals benefited directly from the new currents of exchange, but indirectly millions of Frenchmen were affected by the accelerating tempo of economic life. The circulation of gold specie in the kingdom as a whole rose from 731 million livres in 1715 to some 2 billion livres in 1788. From America to Spain—whose trade with its colonies was under the informal influence and in many instances the informal control of French merchants—silver bullion found its way to northern and eastern France and thence to the eastern Mediterranean, where French influence was widely felt: Bonaparte's Egyptian expedition of 1798 had far-ranging diplomatic, cultural, and economic origins.

Centres of intellectual transformation

Cities. Commerce rather than industry buoyed up French cities, especially the Atlantic seaports. In 1789, 15 percent of Frenchmen lived in cities with more than 2,000 inhabitants. Paris, a city of about 500,000 inhabitants, was only half the size of London, the world's largest seaport. But regardless of their size, French cities were centres of intellectual transformation on the Continent. It was there, in the Sociétés de Pensées, Masonic Lodges, and some 32 provincial academies, that writers found their public. There also took place the cultural revolution that inspired the writers in turn and the economic changes that gave momentum to the cultural upheaval. Although most French cities, especially in central and eastern France, remained unaffected by these changes, many seaports—together with those inland cities benefiting from good avenues of communication—did well or even boomed.

CULTURAL TRANSFORMATION

The Enlightenment. The industrial and commercial developments, already significant by themselves, were the cause, and perhaps also the effect, of a wider and still more momentous change preceding the Revolution—the Enlightenment. Today the Enlightenment can be understood as the conscious formulation of a profound cultural transformation. Epistemologically, the French Enlightenment relied on three sources: rationalism, which had in France a strong tradition dating to Descartes; empiricism, which was borrowed from English thought and which in France underpinned the work of such writers as Claude-Adrien Helvetius (1715–71), Paul-Henri Dietrich, Baron d'Holbach (1723–89), Étienne Bonnot de Condillac (1715–80), and Julien Offroy de La Mettrie (1709–51), the author of a book eloquently entitled *L'Homme machine* (*Man a Machine*); and an amorphous concept of nature that was particularly strong in the immensely popular and important work of Jean-Jacques Rousseau (1712–78) and, in the 1780s, in the works of widely read pre-Romantic writers like Jacques-Henri Bernardin de Saint-Pierre (1737–1814).

Though far apart from one another in a strict philosophical sense, these sources of inspiration generated a number of shared beliefs that were of obvious political consequence. The enlightened subjects of Louis XV and Louis XVI were increasingly convinced that French institutions of government and justice could be radically improved. Tradition seemed to them an increasingly inadequate principle to follow in such matters. Meliorism, gauged especially by the progress of the sciences, was one of the cardinal beliefs of the age. Regarding the economy, physiocrats like the king's own doctor, François Quesnay (1694–1774), praised the virtue of free-market economics and, as they put it, of "laissez-faire, laissez-aller." Widely associated with the humane and rational criticism of religious intolerance and of judicial error were the names of Montesquieu, of the encyclopaedist Denis Diderot (1713–84)—from the first French *Encyclopédie,* published from 1751 to 1772—and, most importantly, of Voltaire (1694–1778). Especially renowned was Voltaire's defense of the Protestant merchant Jean Calas, unjustly broken on the wheel in 1762 for the supposed murder of his suicidal son.

The influence of Rousseau. Regarding the cultural transformations of 18th-century France, it would be difficult to overestimate the crystallizing and revolutionary impact of Rousseau's vision of the world. His thought changed conceptions both of man's private and public spheres. According to Rousseau the self becomes empowered in private union with the beloved other, as portrayed in his immensely popular novel *Julie: ou, la nouvelle Héloïse* (1761; *Julie: or, The New Eloise*), or in public union with one's fraternally minded fellow citizens, as explained in *Du contrat social* (1762; *The Social Contract*), a work less well-known but even more symptomatic of change.

The cultural transformation affecting the domestic sphere ennobled the roles of women as wives and mothers. The nature of masculine and feminine sexuality became a favoured topic for writers, doctors, pamphleteers, or pornographers (some of whom, like Restif de la Bretonne, or even Diderot, were in other respects writers of considerable stature). Moralists reflected anew on the responsibility of children to their parents and on the obligation of mothers to breast-feed their children. At this time the majority of babies born in the cities were sent to be wet-nursed in the country; indeed, more than 80 percent of babies born in Paris in the 1780s were sent out to be suckled by professional nurses. The appeal to mothers to nurture their own children came from Rousseau himself.

Education

Pedagogic questions were widely discussed, and the possibility of creating national systems of education acquired sudden importance. The French administrator, reformer, and economist Anne-Robert-Jacques Turgot, Baron de l'Aulne (1712–81), expressed the new sensibility when he wrote that the education of children was the basis of national unity and mores. The whole emphasis of education shifted. Whereas education before had as its primary purpose the adaptation of the young to established patterns of culture and thought, it now placed a greater emphasis on the individual desires and propensities of children.

In 1763 an otherwise reactionary *parlementaire* named La Chalotais even put forward a scheme for lay and national primary education. An important landmark in this respect too was the expulsion from France in 1764 of the Jesuits, who had theretofore dominated French secondary education. Increasingly, the French language was substituted for Latin in the secondary schools, or *collèges* (the forerunners of today's lycées). Rhetoric gave way to an emphasis on more "natural" manners and modes of expression. History was raised to the level of a serious discipline; with Voltaire's *Siècle de Louis XIV* (1751; *Age of Louis XIV*), modern French historiography began, and there were echoes of this new attitude in the programs of the secondary schools, which added mathematics, physics, and geography to their curriculum.

The 18th-century cultural transformation also redefined the public roles of men as would-be citizens of a harmonious polity. In 17th-century Jansenist thought, man was seen as a guilt-ridden creature who desperately needed God's grace in order to realize his true and hidden self. This vision of man as fallen and of God as hidden had drawn the French bourgeoisie toward introspection and away from politics. It had made absolutism possible. But, in the prerevolutionary decades of the 18th century, Rousseau, whose writings best expressed the transformed sensibility, transcended this cultural inheritance. In his understanding, man was still a fallen creature because society, through which he was fated to realize his nobler self, had drifted away from primitive simplicity. Man, however, might potentially be good by nature. Thus, though presently fallen, he might save himself by simplifying his private life and above all by purifying the public, social, and political institutions affecting him. In Rousseau's imagination, self-realization was to take place within the world and not against it, as Jansenists like Pascal had proposed.

Self-realization within the world

Exposure to writers like Diderot, Guillaume-Thomas-François Raynal (1713–96), author of an anticolonialist *Histoire des deux Indes* (1770; *History of the Two Indies*), and Jean-Jacques Barthélémy (1716–95), to painters like Jacques-Louis David (1748–1825) and Joseph-Marie Vien (1716–1809), to musicians like Christoph Gluck (1714–87), and to visionary architects like Claude-Nicolas Ledoux (1736–1806) and Étienne-Louis Boullée (1728–99) enabled the educated public of the 1770s and '80s to pursue and sharpen their new insights. It allowed them to explore the limits of the private domain as well as to clarify their new understanding of the public good. These radical ideas had transforming power. Rousseau's message especially appealed to the deeper instincts of his contemporaries, inspiring them with a quasi-utopian view of what might be done in this world.

The ideological or cultural transformation was in some ways limited to a narrow segment of society. In 1789 only one-third of the population, living for the most part in northern and eastern France, could both read and write French. (Outside the aristocracy and upper bourgeoisie, literacy for women was considerably below that of men.) About one-third of the king's subjects could not even speak French. Nonetheless, even though probably not much more than half a million people were directly involved in the cultural upheaval, their influence was decisive.

Relaxation of censorship

The concerns of the new "high culture" were intensely personal and, for that reason, deeply felt, even by people who did not participate in it directly. Readers of sentimental prose might after all also be employers, husbands, and fathers, who would treat their dependents differently. In addition, the means through which new cultural forms were diffused were often original, and in any case, sustained. Between 1723 and 1789 more than 30,000 books were published. Newspapers, some of them from abroad, were widely read (and manipulated by the royal government in order to influence opinion). Many pamphleteers were ready to be hired by whoever had money to pay for their services. Lawyers published their briefs. Theatrical performances like Pierre-Augustin Caron de Beaumarchais's comedy *Le Mariage de Figaro* (1784; *The Marriage of Figaro*), which openly exposed aristocratic privilege, were widely publicized events. In the 1780s censorship became increasingly desultory. Public opinion, whose verdict was identified by the middle class not with the expression of its own particular desires but as the voice of universal common sense and reason, became a tribunal of ideological appeal, an intellectual court of last resort, to which even the monarchy instinctively appealed.

These sweeping changes had created a country that by 1788 was deeply divided ideologically and economically. The salons of Paris, many of them directed by women, were the worldwide focus of a rationalist and atheistic Enlightenment; both Catherine the Great and Thomas Jefferson, though far removed from each other in most respects, shared an abiding interest in the latest intellectual fashions from Paris. But, whatever held true for influential circles, most Frenchmen in these same years remained deeply religious, certainly in the provinces but possibly in Paris as well. Most of the books and pictures Parisians bought on the eve of the Revolution were still related to religious themes. The country was also divided economically; whereas France's foreign trade was very lively, most of the rural communities were, by English standards, unproductive and immobile villages.

THE POLITICAL RESPONSE

The historical debate. In broad terms, 18th-century French politics could be defined as the response of the monarchic state to the emergence of the new cultural and economic configurations that had transformed the lives and especially the imaginations of French men and women. The question was whether the Bourbon monarch could rationalize its administration and find a way to adapt itself in the 1770s and '80s to the new perception of the relationship between citizen and state as it had come to be defined by the Enlightenment, especially by Rousseau.

On the issue of political mutation historical opinion is divided. One set of discussions revolves around the issue of whether the monarchy's efforts at modernization were sufficient; whereas some historians believe that the ancien régime almost succeeded, first in the 1770s and once again in the early 1780s, others argue more pessimistically that the efforts of the monarchy were insubstantial. A more radical view, by contrast, holds that the extent of reform was irrelevant because no monarch, however brilliant, could have met the rising liberal and nationalist expectations of tens of thousands of dissatisfied and vocal people, steeped in Enlightenment thought, who were committed to becoming the empowered citizens of a fraternal state.

The weight of evidence appears to be that the monarchy was by the late 1780s doomed to destruction, both from its inability to carry on the absolutist, administrative work formerly accomplished by men like Colbert and by the nature of its critics' desires; the gap separating the Roman Catholic traditionalism of the monarchy and the neoclassical ambitions of nascent public opinion was too wide.

Assessment of foreign policy

Foreign policy and financial crisis. The monarchy's international performance from 1715 to 1783 was basically creditable. From the time of the War of the Spanish Succession (1701–14), when France had been invaded and nearly beaten, French statesmen pursued a double goal—the preservation of the balance of power in Europe, and, in the world at large, the expansion of the French colonial empire and the containment of England. To achieve the first goal, France, during the War of the Austrian Succession (1740–48), sided with Prussia and against Austria, which was then thought the more dangerous power. Rather reluctantly, during the Seven Years' War, France reversed its position and fought against Prussia, whose efforts at aggrandizement had become a threat to the status quo. In the 1770s and '80s French diplomacy worked to preserve both the continental status quo and the continued independence of the smaller European states, many of which were its clients or allies—notably Poland, Sweden, the United Provinces, and Turkey. In this the French were reasonably successful; although they suffered reverses in Poland, which was partitioned, and in the United Provinces, where the Anglo-Prussian Conservative Party with Prussian military help overcame the pro-French liberal groups in 1787, the balance of power in Europe was preserved.

French successes vis-à-vis England, however, were checkered. Efforts to extend French rule in India or to preserve it in Canada were more or less successful in the 1740s but, as stated above, were totally unsuccessful during the Seven Years' War. During that conflict France suffered grievously in spite of the entente between France and Spain, both ruled by Bourbon monarchs, and in spite of the Austrian alliance. France was unable to prevail either on the Continent or in the colonies and, for having tried too much, it failed everywhere. French influence was at a very low ebb in 1763. During the U.S. War of Independence (1775–83), however, the French were most careful not to be also involved in the Austro-Prussian "Potato War" (War of the Bavarian Succession) of 1778–79, and, by concentrating their efforts for the first time on maritime matters, they succeeded in holding and even reversing the advance of England. A contemplated invasion of England did not take place, but for a short while the French navy had control of the high seas. The real victor of the battle of Yorktown, Pa. (1781), in which the British were defeated, was less General George Washington than Admiral François-Joseph-Paul de Grasse (1722–88), whose fleet had entered Chesapeake Bay. Thus, on balance, France more or less succeeded in holding its own in Europe while preserving its colonial empire.

The costs of war

Nonetheless, regardless of defeat or victory, colonial and naval wars were problematic because of their prohibitive cost. In Bourbon France (as in Hanoverian England and the Prussia of the Fredericks) a high percentage of the governmental income was earmarked for war. Navies were a particularly costly commodity. The crown's inability to manage the ever-swelling deficit finally forced it to ask the country's elites for help, which, for reasons unrelated to the various wars and conflicts, they were utterly unwilling to extend unconditionally. Money thus was a large factor in the collapse of the monarchy in 1789.

Ultimately, to be sure, it was not the crown's inability to pay for wars that caused its downfall. Rather, the crown's extreme financial difficulties could have led to reforms; the need for funds might have galvanized the energies of the monarchy to carry forward the task of administrative reordering begun during the reigns of Louis XIII and Louis XIV. A more determined king might have availed himself of the problems raised by the deficit in order to overwhelm the defenders of Roman Catholic traditionalism. In so doing, the monarchy might have satisfied enough of the desires of the Enlightenment elite to defuse the tense political situation of the late 1770s and '80s. Although in 1789 a program of "reform from above" was no longer possible, it might well have succeeded in the early 1770s.

Domestic policy and reform efforts. As stated above, in the context of 17th-century absolutism, Louis XIV had already initiated many rationalizing reforms. The crown had worked selectively to replace corporatist, traditionalist institutions with meritocratic associations. In 1648, for example, Cardinal Mazarin had already sponsored a Royal Academy of Painting and Sculpture (because it lent itself better to control by the state) as an alternative to the traditional guilds and corps. This statist and anticorporatist program was now embraced, but in a more liberal register, by the Enlightenment partisans of meritocratic individualism. Though Montesquieu had defended intermediary bodies such as guilds as guarantees of civic liberty, thinkers of the Enlightenment attacked them in the name of public utility and of what would later be called the rights of man. In an article written for the *Encyclopédie,* Turgot denied the sanctity of what he called foundations: "Public utility is the supreme law, and cannot be countervailed by a superstitious respect for what has been called the intents of the founders." Most foundations, he thought, had as their only purpose the satisfaction of frivolous vanity. At the other end of the social spectrum, the Protestant Rabaut Saint-Étienne, later president of the National Assembly, argued that "every time one creates a corporate body with privileges one creates a public enemy because a special interest is nothing else than this." No distinction was made between private interest and factional selfishness; in 1786 the future Girondin leader Jacques Brissot was expressing what had become a commonplace when he wrote that "the history of all intermediary bodies proves, in all evidence, that to bring men and to bind men together is to develop their vices and diminish their virtues." Private benevolence applied to public purpose was loudly praised in the 1780s, and Louis XVI's finance minister, Jacques Necker, did a great deal for his reputation by endowing a hospital for sick children, which stands to this day. By 1789 public and charitable concern had become the themes of countless didactic works of literature and painting.

The monarchy's reform efforts

Many of the monarchy's efforts to institutionalize this new sensibility were often significant. The crown encouraged not only agriculture but also manufacturing and commerce. It allowed tax exemptions for newly cultivated land. It subsidized the slave trade, on which much of the prosperity of the Atlantic seaports was based. It improved communications and in 1747 founded a School of Bridges and Roads to train civil engineers for the royal engineering service that had existed since 1599. In the provinces, in Bordeaux especially, many intendants took an active role in road building and in the modernization of urban space. The crown's administrators also gave sustained thought to the abolition of internal customs and to the creation of what would have been the largest free-trade zone in Europe at the time. Social mobility was made possible; after 1750 many successful merchants and bankers were ennobled.

These were important steps. But the royal bureaucrats tried to go much further in regard to both the rationalization of the state's financial machine and the meritocratic individuation of social and economic forms.

Tax reform. In 1749–51 Jean-Baptiste de Machault d'Arnouville, then comptroller general of finances, proposed a partial reform of the tax system, his particular concern being to restrict the financial power of the church. In 1764 and 1765 another comptroller general, François de L'Averdy, attempted a reform of municipal representation and administration. All royal officials understood the need to reform and rationalize both the imposition and the collection of taxes; many nobles were exempted from taxation, especially in northern France, and many taxes were inefficiently collected by private tax-farmers.

The country's overall fiscal structure was highly irrational, as it had been developed by fits and starts under the goad of immediate need. There were direct taxes, some of which were collected directly by the state: the taille (a personal tax), the capitation, and the *vingtième,* which were a form of income tax from which the nobles and officials were usually exempt. There were also indirect taxes that were paid by everyone: the salt tax, or gabelle, which represented nearly one-tenth of royal revenue; the *traites,* or customs duty, internal and external; and the *aides,* or excise taxes, levied on the sale of items as diverse as wine, tobacco, and iron. All the indirect taxes were extremely unpopular and had much to do with the state's inability to rally the rural masses to its side in 1789. In the 1740s attempts had been made to amend this system but had foundered on the *parlements'* opposition to a more equitable distribution of taxation. By 1770 the swelling debt made it obvious that something should be done. Unpopular measures, such as forced loans, were put into effect. Joseph-Marie Terray, Louis XV's comptroller general of finances, repudiated a part of the debt.

Indirect taxes

Some observers, partisans of enlightened despotism (like Voltaire, who defended it indirectly in his play of 1773 entitled *Les Lois de Minos* [*The Laws of Minos*]) understood that the French monarchy stood in this particular instance for administrative rationalization and progress. But the current of opinion was already moving against the crown. Many writers saw in Terray a tool of royal despotism, plain and simple, and his ministerial colleague René-Nicolas de Maupeou (1714–92) was even more detested for his destruction of the *parlements,* an unusual institution that had become the bastion of conservative opposition to royal reform.

Parlements. The 13 *parlements* (that of Paris being by far the most important) were by their origins law courts. Although their apologists claimed in 1732 that the *parlements* had emerged from the ancient *judicium Francorum* of the Frankish tribes, they had in fact been created by the king in the Middle Ages to dispense justice in his name. With the atrophy of the Estates-General, which had not met since 1614, the *parlements* now claimed to represent the estates when those were not in session. In 1752 a Jansenist *parlementaire,* the Abbé André-René Le Paige, developed the idea that the various *parlements* should be thought of as the "classes" or parts of a larger and single "Parlement de France."

This was a politically significant claim because these courts had taken on many other quasi-administrative functions that were related to charity, education, the supervision of the police, and even ecclesiastical discipline. Royal decrees were not binding, claimed the *parlementaires,* unless the *parlements* had registered them as laws. Although the *parlementaires* admitted that the king might force them to register his decrees by staging a *lit-de-justice,* (*i.e.,* by appearing in person at their session), they also knew that the public deplored such maneuvers, which manifestly went against the grain of the monarch's supposed Christian and paternalist solicitude for the well-being of his subjects.

Various social, cultural, and institutional developments had served to turn the parlements into strongholds of conservative resistance. Since the 17th century the monarchy's need for money and the ensuing venality of offices had enabled the *parlementaires* to buy their offices and to become a small and self-conscious elite, a new "nobility of the robe." In 1604 the creation of the *paulette* tax had enabled the *parlementaires* to make their offices a part of their family patrimony, even if the value of their offices fell somewhat during the course of the 18th century. They had gained status by intermarrying with the older chivalric nobility of the sword. By 1700 the *parlementaires* had become a hereditary and rich landowning elite. (Near Bordeaux, for example, the best vineyards were theirs.) The interregnum of the regency after the death of Louis XIV (1715–23) had given them a chance to recapture some of the ground they had lost during the Sun King's reign; the value of their offices, however, fell again somewhat in the course of the 18th century. The *parlementaires's* Jansenist leanings before 1750 and their recent espousal of antiabsolutism—expressed in the work of Montesquieu, himself a baron and a *parlementaire*—gave this elite ideological consistency.

The *parlementaires*

In 1764 the Jansenist *parlementaires,* as ideological "progressives," secured the expulsion of the Jesuits from France. Then in 1766, as defenders of the Christian social order, they also secured the execution of the 18-year-old Chevalier de la Barre, accused of mutilating a crucifix and owning a copy of Voltaire's *Philosophic Dictionary.* In 1768–69 the Parlement of Brittany, in an antiabsolutist stance, forced the resignation of an appointed royal official, the Duke d'Aiguillon, who had dared to try to limit the power of the local nobility, with whom the Parlement was now in close alliance.

King and *parlements.* In 1770 the *parlements* had reached such power that Louis XV was finally goaded into a burst of absolutist energy. The Paris Parlements, which had dared to attack Terray's financial reform, were dissolved on Jan. 19, 1771. Maupeou was then authorized to create an altogether different set of *parlements* with appointed judges shorn of administrative and political power.

In time, opinion might well have accepted Terray's and Maupeou's reforms. France might then, like Prussia, have avoided revolution from below through the practice of a revolution from above. But the death of Louis XV in 1774 put an end to the experiment. His 20-year-old successor, Louis XVI (ruled 1774–92), unsure of himself and eager to please, recalled the *parlements.* To make matters worse, an indirect repetition after 1774 of this same cycle, with the renewed victory of the *parlementaires* over the enlightened royal bureaucracy, set the seal of doom on the absolutist ancien régime.

In late 1774 Louis XVI appointed Turgot, a former intendant, comptroller general. Perhaps because he thought that the success of his reforms would guarantee their acceptance, perhaps also because he thought it vain to attack the Parlement directly so soon after Maupeou's dismissal, Turgot carried through his measures without first destroying the institutional bases of privileged conservatism. He left the Parlement alone and attempted instead to reduce government expenditures and to alter the methods of tax collecting. In accordance with his physiocratic laissez-faire principles, he freed the corn trade from restraint; he suppressed the corvée, or forced labour service, exacted from the peasants; and abolished the guilds, which had limited both access to artisanal professions and the competition within them. Finally, he suggested that Protestants should be given freedom of conscience. In short, Turgot attempted to rationalize the administrative practices of the French state and to individuate French social and economic life. The solution to the financial crisis, he thought, would come not through the state's appropriation of a larger share of extant resources but from the expansion of the nation's ability to produce and pay. The strength of creative individualism, he thought, would break the political impasse.

Turgot's reforms

In May of 1776, however, Turgot was dismissed. Opposition to his measures had come from all sides: a poor harvest had sparked peasant disturbances, the clericalists were antagonized by Turgot's philosophical friends (his greatest and most loyal disciple was Marie-Jean-Antoine-Nicolas de Caritat, Marquis de Condorcet, the future

Girondin), and, when the Parlement of Paris once again refused to register the new edicts, Louis abandoned Turgot as he had dismissed Maupeou. Thenceforth, the state carried through only minor reforms, none of them on a scale commensurate with the needs felt by the Enlightenment bourgeoisie and notables of the cities and towns. The vestiges of serfdom were suppressed in 1779, and restrictions were removed from the Jews in 1784. In 1786 the salaries of the poorer country clergy were raised, and there were also improvements in the organization of the navy and the army (especially of the artillery, in which young Napoleon became a second lieutenant in 1786). Judicial procedure was also revamped: in 1780 torture was abolished, and in 1784 the king's use of lettres de cachet for purposes of arbitrary imprisonment without trial was considerably curtailed. But these were minor adjustments. Nothing was done to solve the fundamental problems of the organization of society and of the state in a manner that would be acceptable to progressive public opinion.

By the mid-1780s the state's position had in fact become truly hopeless. Resentment had risen to the point where no concession would suffice; as a gift of the crown, no reform could be acceptable. Most remarkable was the lack of success of deliberative provincial assemblies, elected by large landowners without regard to social class; their function was to help forge the consensus necessary for reforms, especially in the area of taxation. They would have been seen as an incredible concession 20 years before; in the 1770s and '80s they were failures. The gap between the state and the public was so great that the state could now do nothing right.

But the problem of the state was complicated by the fact that in the 1780s most of what it did was actively and positively wrong. Having alienated conservative opinion by its attempted reforms and enlightened opinion by its failure to push them through, the crown had no constituency on which it could rely; its only strategy was to keep things as they were, in the hope of proceeding somehow from expedient to expedient. The U.S. War of Independence, however, was a most inexpedient event. This was not due to its military denouement, for, as stated, in spite of some naval reverses in 1783, the French army and navy performed creditably during that conflict, and the position and prestige of France in Europe was greater in 1783 than it had been for 40 years. The French problem in the war was not military but financial. The cost of the war was enormous, and it was met not by new taxation but by new borrowing, which doubled the size of the national debt. In the late 1780s the service of the funds absorbed more than half the crown's income: by 1789 debt payments had risen to 300 million livres from less than 100 million before the American war. This could not go on forever, and indeed it was only because of the talent of Jacques Necker (Turgot's successor) in raising loans that the system went on as long as it did. But sooner or later, from sheer financial exhaustion, the state would have to turn to the nation, and at that point the whole set of conflicts in society—between country and city, bourgeois and noble—would have to be resolved.

Cost of the American War

Loss of prestige. The absolutist principle of monarchy seemed exhausted, as was the crown's traditionalist and religious prestige. The prestige of Louis XIV had been immense; when Voltaire wrote of the "grand siècle," it was the 17th century he meant and not his own. Gradually, however, the monarchy had lost its sacred aura.

Genuinely popular in the earlier years of his reign, Louis XV had become thoroughly discredited by the time of his death. Although his liaison with Mme de Pompadour had borne many fruits in the form of the patronage she extended to artists as different as Voltaire and the architect Jacques-Ange Gabriel, it did nothing for the prestige of the crown. More unpopular yet was Louis XV's last mistress, Mme du Barry, a former prostitute. The king was also thought to maintain a private brothel (which was true) and to have literally starved his people by speculating on a rising price for grain (which was false).

It is difficult to know if Louis XV's lack of popularity was due to his own actions or to a decline in the prestige of the monarchy. By contrast, Louis XV's grandson and successor, Louis XVI—well-meaning, obtuse, and sexually incompetent—was initially more popular; this would seem to suggest that the crown in the 1770s could still tap the traditional sources of loyalty. But by the 1780s Louis XVI was held in contempt as well; his wife, Marie-Antoinette, was also much hated. Never popular because she was by birth a member of the Austrian ruling house, which in France was traditionally disliked, she reached in 1785 a nadir of unpopularity during the prosecution of the Affair of the Diamond Necklace. (This case revolved around a cardinal, the Prince de Rohan, who had been tricked into giving a diamond necklace to a woman whom he thought to be the queen; in this instance Marie-Antoinette was blameless, but what was seized upon by public opinion was that a cardinal had thought it possible to seduce and bribe the queen.) The discredit that befell the monarchy in consequence was immense, and Napoleon dated the beginning of the French Revolution from this very episode.

Loss of control. By August 1786 even Necker's successor, the frivolous if intelligent Charles-Alexandre de Calonne (1734–1802), had concluded that the French state was coming to a dead end. Although the crown had assured the moneymen that it would not default on the debt, as indeed it could not have done without alienating thousands of its natural supporters, Calonne found that he could no longer raise funds by borrowing. To resolve the ensuing impasse, in February of 1787 he summoned to Versailles the Assembly of Notables, which represented the privileged orders—great nobles, bishops, *parlementaires*—in the hope that they would finally and of their own accord undertake the long-resisted transformation of the state. But the notables refused again, as the *parlementaires* had in 1776, this time on the grounds that Calonne's mismanagement was the only cause of the crown's problems. They argued that if Calonne were replaced by Necker, who had borrowed so successfully, all would be well. Once again, the crown yielded. Calonne was replaced by Loménie de Brienne, a cardinal, though an atheist, and a spokesman of the privileged majority of the Assembly of Notables. Almost at once Loménie reversed himself and came to Calonne's conclusion: the state could not go on as it had. The notables, however, refused to be more amenable to Loménie than they had been to Calonne. Despairing of securing the consent of the privileged orders, Loménie dismissed the assembly in May of 1787, and in August the Paris Parlement was exiled to Troyes.

Opposition of the notables

But these measures were desperate, and already the monarchy was beginning to lose control of the political process. Indeed, for the next two years it merely floundered from one scheme to another, in the impossible hope of squaring the circle of modernistic reform, popular hostility, respect of privilege, and the preservation of royal absolutism. Essentially unwilling to force the privileged notables to yield their corporate rights, the crown was unable to assert any coherent policy. The Parlement was therefore recalled from Troyes in September of 1787, again dismissed in May of 1788, and, in the face of a beginning of a breakdown of law and order and of the inability of officials to collect taxes, once more recalled to Paris by the crown in May of 1788.

Paradoxically, the return of the reactionary *parlementaires* was saluted as a great victory by their most bitter reformist opponents. This is to be explained by the fact that the crown was now perceived by all Frenchmen as inimical: the conservative *parlementaires* opposed it from their reactionary point of view, and the reformists opposed it for its arbitrary repression even of the reactionaries. The crown had become essentially powerless, and on Aug. 8, 1788, it tacitly accepted this fact by agreeing to call together the Estates-General on May 1 of the following year. At that juncture the monarchy in fact dropped out of the political debate, which would now be structured by the tensions within French society. Censorship was in practice suspended (formally in mid-May 1789), and thousands of pamphlets circulated in Paris.

Composition of the forthcoming Estates

The popularity of the Parlement was, however, shortlived. Opinions were polarized regarding the composition of the forthcoming Estates and the procedures to be followed. Debate revolved around the issue of whether they should meet in three groups of equal size (a reinscription of traditional modes of representation) or whether the Third Estate should be doubled in size and the deputies meet together (a step toward the recognition that sovereignty lay with the representatives of the people and not the king). The Parlement of Paris, which had returned in triumph on Sept. 23, 1788, decided on September 25 that the three Estates should meet as before. At once the popularity of the *parlementaires* collapsed. On September 23, they had been seen as victims of royal oppression. Two days later, they were perceived to be what they had in fact long since become, the defenders of the traditional social and political fabric of the ancien régime. In a last and fitful assertion of authority, at the behest of Necker, once again minister, the crown decided on December 27 to overrule the Parlement. The Estates, it resolved, would meet separately, but the Third Estate would have as many deputies as the other two orders combined. The stage was set for the coming Revolution.

THE CAUSES OF THE FRENCH REVOLUTION

In an immediate sense, what brought down the ancien régime was its own inability to change or, more simply, to pay its way. The deeper causes for its collapse are more difficult to establish. One school of interpretation maintains that French society under the ancien régime was rent by class war. This position implies that the French Revolution revolved around issues of class; it has led to the class analysis of prerevolutionary society as well as to the class analysis of the opposing Revolutionary factions of Girondins and Montagnards and, more generally, to what the historian Alfred Cobban called "the social interpretation of the French Revolution."

In keeping with this interpretation, Marxist historians of the 1930s emphasized that the French 18th-century bourgeoisie had assumed a distinct position in French society in that it was in control of commerce, banking, and industry. Revisionist historians in the 1980s, however, responded that the bourgeoisie had no monopoly in these sectors; nobles were also heavily involved in foreign trade, in banking, and in some of the most modern industries, such as coal mining and chemicals.

Most historians today would argue that on balance it was becoming increasingly difficult to distinguish clearly between the nobility and the bourgeoisie. Like most nobles, wealthy French nonnobles were landlords and even owners of seigneuries, which were bought and sold before 1789 like any other commodity. Although one can speak of a secularized "bourgeois" ethic of thrift and prudence that had come into its own (symbolized by the oath, the opposite of the aristocratic and ephemeral fireworks), supporters of this ethic, as of the Enlightenment ethic, were both noble and nonnoble.

Aristocratic privileges

There were two areas, however, in which the nobility enjoyed important institutional privileges: the upper ranks of the army and the clergy were, in the main, aristocratic preserves and had become more so in the 1780s. Henri de Boulainvilliers, in his posthumous essays of 1732 on the nobility of France, had even developed a wholly fraudulent but widely praised theory of noble racial superiority. Thus, there were some issues on which all of the bourgeoisie might unite against most of the nobility. But such issues, it is now claimed, were relatively unimportant.

Contemporary historical work has refocused the discussion regarding the causes for the Revolution. Studying the representation of politics, the shape of Revolutionary festivals, the Revolutionary cults of sacrifice and heroism, scholars have come to place the transformation of culture at the core of their discussion. What really mattered was the desacralization of the monarchy, the new understanding of the self and the public good, and the belief that thinking individuals might seize the state and fundamentally reshape it. Other historians, by contrast, have emphasized the persistent liabilities that French political culture carried through the Enlightenment, such as the suspicion of dissent and the readiness to rely on force in order to subvert it.

From either of these two perspectives, it follows that the prospects of the monarchy's survival were dim in 1788. Many government officials, it is true, were finely attuned to public opinion. The vast neorepublican canvases of Jacques-Louis David, such as his "Oath of the Horatii" (1784) glorifying traditional republicanism, were commissioned by the king's dispenser of patronage, the Marquis d'Angivillers, a friend of Turgot. Visionary architects, developing a style of Revolutionary Neoclassicism, similarly received royal commissions for new public works. Chrétien-Guillaume de Lamoignon de Malesherbes (1721–94), another friend of Turgot and like him a minister of the crown, protected the *encyclopédistes.* On balance, however, it is hard to see how the monarchy, even if it had resolved its financial problems, which it was very far from doing, could have extended this ecumenism from art to politics and social life. To do so, it would have had to transform its institutions in keeping with new conceptions regarding men's public and private affairs and to commit itself to the rejection of the corporatist ethic in economic life. Thus the monarchy seemed fated to failure and the stage set for revolution. (P.Hi.)

The French Revolution and Napoleon, 1789–1815

THE DESTRUCTION OF THE ANCIEN RÉGIME

1789: the convergence of revolutions. *The juridical revolution.* Louis XVI's decision to convene the Estates-General in May 1789 became a turning point in French history. When he invited his subjects to express their opinions and grievances in preparation for this event—unprecedented in living memory—hundreds responded with pamphlets in which the liberal ideology of 1789 gradually began to take shape. Exactly how the Estates-General should deliberate proved to be the pivotal consciousness-raising issue. Each of the three Estates could vote separately (by order) as they had in the distant past, or they could vote jointly (by head). Because the Third Estate was to have twice as many deputies as the others, only voting by head would assure its preponderant influence. If the estates voted by order, the clergy and nobility would effectively exercise a veto power over important decisions. Most pamphleteers of 1789 considered themselves "patriots," or reformers, and (though some were nobles themselves) identified the excessive influence of "aristocrats" as a chief obstacle to reform. In his influential tract *Qu'est-ce que le tiers état?* (1789; *What is the Third Estate?*) the constitutional theorist Emmanuel-Joseph Abbé Sieyès asserted that the Third Estate really was the French nation. While commoners did all the truly laborious and productive work of society, he claimed with some exaggeration, the nobility monopolized its lucrative sinecures and honours. As a condition of genuine reform, the Estates-General would have to change that situation.

A seismic shift was occurring in elite public opinion. What began in 1787–88 as a conflict between royal authority and traditional aristocratic groups had become a triangular struggle, with "the people" opposing both absolutism and privilege. A new kind of political discourse was emerging, and within a year it was to produce an entirely new concept of sovereignty with extremely far-reaching implications.

Patriots were driven to increasingly bold positions in part by the resistance and bad faith of royal and aristocratic forces. It is not surprising that some of the Third Estate's most radical deputies came from Brittany, whose nobility was so hostile to change that it finally boycotted the Estates-General altogether. Hoping that the king would take the lead of the patriot cause, liberals were disappointed at the irresolute, business-as-usual attitude of the monarchy when the Estates opened at Versailles in May 1789. While the nobility organized itself into a separate chamber (by a vote of 141 to 47), as did the clergy (133 to 114), the Third Estate refused to do so. After pleading repeatedly for compromise and debating their course of action in the face of this deadlock, the Third Estate's deputies finally acted decisively. On June 17 they proclaimed that they were not simply the Third Estate of the Estates-General but a National Assembly, which the other deputies were invited to join. A week later 150 deputies of the clergy did indeed join the National Assembly, but the nobility protested that the whole notion was illegal.

Now the king had to clarify his position. He began by closing the hall assigned to the Third Estate and ordering all deputies to hear a royal address on June 23. The deputies, however, adjourned to an indoor tennis court on the 21st and there swore a solemn oath to continue meeting until they had provided France with a constitution. Two days later they listened to the king's program for reform. In the "royal session" of June 23 the king pledged to honour civil liberties, agreed to fiscal equality (already conceded by the nobility in its *cahiers*, or grievance petitions), and promised that the Estates-General would meet regularly in the future. But, he declared, they would deliberate separately by order. France was to become a constitutional monarchy, but one in which "the ancient distinction of the three orders will be conserved in its entirety." In effect the king was forging an alliance with the nobility, who only a year before had sought to hobble him. For the patriots this was too little and too late.

The Tennis Court Oath

In a scene of high drama, the deputies refused to adjourn to their own hall. When ordered to do so by the king's chamberlain, the Assembly's president, astronomer Jean-Sylvain Bailly (1736–93), responded—to the official's amazement—that "the assembled nation cannot receive orders." Such defiance unnerved the king. Backing down, he directed the nobles several days later to join a National Assembly whose existence he had just denied. Thus the Third Estate, with its allies in the clergy and nobility, had apparently effected a successful nonviolent revolution from above. Having been elected in the *bailliages* (the monarchy's judicial districts which served as electoral circumscriptions) to represent particular constituents to their king, the deputies had transformed themselves into representatives of the entire nation. Deeming the nation alone to be sovereign, they as its representatives claimed sole authority to exercise that sovereignty. This was the juridical revolution of 1789.

The juridical revolution

Parisian revolt. In fact, the king had by no means reconciled himself to this revolutionary act. His concession was a strategic retreat until he could muster the military power to subdue the patriots. Between June 27 and July 1 he ordered 20,000 royal troops into the Paris region, ostensibly to protect the assembly and to prevent disorder in the restive capital. The assembly's pleas to the king to withdraw these menacing and unnecessary troops fell on deaf ears. For all their moral force, the deputies utterly lacked material force to counter the king's obvious intentions. The assembly was saved from likely dissolution only by a massive popular mobilization.

During the momentous political events of 1788–89 much of the country lay in the grip of a classic subsistence crisis. Bad weather had reduced the grain crops that year by almost one-quarter the normal yield. An unusually cold winter compounded the problem, as frozen rivers halted the transport and milling of flour in many localities. Amidst fears of hoarding and profiteering, grain and flour reserves dwindled. In Paris the price of the four-pound loaf of bread—the standard item of consumption accounting for most of the population's calories and nutrition—rose from its usual 8 sous to 14 sous by January 1789. This intolerable trend set off traditional forms of popular protest. If royal officials did not assure basic food supplies at affordable prices, then people would act directly to seize food. During the winter and spring of 1789 urban consumers and peasants rioted at bakers and markets and attacked millers and grain convoys. Then, in July, this anxiety merged with the looming political crisis at Versailles. Parisians believed that food shortages and royal troops would be used in tandem to starve the people and overwhelm them into submission. They feared an "aristocratic plot" to throttle the patriot cause.

When the king dismissed the still-popular finance minister Jacques Necker on July 11, Parisians correctly read this as a signal that the counterrevolution was about to begin. Instead of yielding, however, they rose in rebellion. Street-corner orators such as Camille Desmoulins stirred their compatriots to resist. Confronting royal troops in the streets, they won some soldiers over to their side and induced officers to confine other potentially unreliable units to their barracks. On July 13, bands of Parisians ransacked armourers' shops in a frantic search for weapons. The next day a large crowd invaded the Hôtel des Invalides and seized thousands of rifles without resistance. Then they moved to the Bastille, an old fortress commanding the Faubourg Saint-Antoine, which had served as a notorious royal prison earlier in the century but was now scheduled for demolition. Believing that gunpowder was stored there, the crowd laid siege to the Bastille. Unlike the troops at the Invalides, the Bastille's tiny garrison resisted, a fierce battle erupted, and dozens of Parisians were killed. When the garrison finally capitulated, the irate crowd massacred several of the soldiers. In another part of town two leading royal officials were lynched for their presumed role in the plot against the people. Meanwhile the electors of Paris, who had continued to meet after choosing their deputies to the Estates-General, ousted the royal officials of the city government, formed a revolutionary municipality, and organized a citizens' militia or national guard to patrol the streets. Similar municipal revolutions occurred in 26 of the 30 largest French cities, thus assuring that the capital's defiance would not be an isolated act.

The fall of the Bastille

By any standard, the fall of the Bastille to the Parisian crowd was a spectacular symbolic event—a seemingly miraculous triumph of the people against the power of royal arms. The heroism of the crowd and the blood of its martyrs—ordinary Parisian artisans, tradesmen, and workers—sanctified the patriot cause. Most importantly, the elites and the people of Paris had made common cause, despite the inherent distrust and social distance between them. The mythic unity of the Third Estate—endlessly invoked by patriot writers and orators—seemed actually to exist, if only momentarily. Before this awesome material and moral force Louis XVI capitulated. He did not want civil war in the streets. The Parisian insurrection of July 14 not only saved the National Assembly from dissolution but altered the course of the Revolution by giving it a far more active, popular, and violent dimension. On July 17 the king traveled to Paris, where he publicly donned a cockade bearing a new combination of colours: white for the Bourbons and blue and red for the city of Paris. This tricolour was to become the new national flag.

Peasant insurgencies. Peasants in the countryside, meanwhile, carried on their own kind of rebellion, which combined traditional aspirations and anxieties with support of the patriot cause. The peasant revolt was autonomous, yet it reinforced the urban uprising to the benefit of the National Assembly.

Competition over the ownership and the use of land had intensified in many regions. Peasants owned only about 40 percent of the land (see above *Agricultural patterns*), leasing or sharecropping the rest from the nobility, the urban middle class, and the church. Population growth and subdivision of the land from generation to generation was reducing the margin of subsistence for many families. Innovations in estate management—the grouping of leaseholds, conversion of arable land to pasture, enclosure of open fields, division of common land at the lord's initiative, discovery of new seigneurial dues or arrears in old ones—exasperated peasant tenants and smallholders. Historians debate whether these were capitalistic innovations or traditional varieties of seigneurial extraction, but in either case the countryside was boiling with discontent over these trends as well as over oppressive royal taxes and food shortages. Peasants were poised between great hopes for the future raised by the calling of the Estates-General and extreme anxiety—fear of losing land, fear of hunger (especially after the catastrophic harvest of 1788), and fear of a vengeful and mighty aristocracy.

In July peasants in several regions sacked the castles of nobles and burned the documents that recorded their feudal obligations. This peasant insurgency eventually merged into the movement known as the Great Fear. Rumours abounded that these vagrants were actually brigands in the pay of nobles, who were marching on villages to destroy the new harvest and coerce the peasants into submission. The fear was baseless, but hundreds of false alarms and panics stirred up hatred and suspicion of nobles, led peasants to

The Great Fear

arm themselves as best they could, and set off widespread attacks on chateaus and feudal documents. The peasant revolt suggested that the unity of the Third Estate against "aristocrats" extended from Paris to villages across the country. The Third Estate truly seemed invincible.

The abolition of feudalism. Of course the violence of peasant insurgency worried the deputies of the National Assembly; to some it seemed as if the countryside were being engulfed by anarchy that threatened all property. But the majority was unwilling to turn against the rebellious peasants. Instead of denouncing their violence, they tried to appease peasant opinion. Liberal nobles and clergy began the session of August 4th by renouncing their ancient feudal privileges. Within hours the Assembly was propelled into decreeing "the abolition of feudalism" as well as the church tithe, venality of office, regional privilege, and fiscal privilege. A few days later, to be sure, the Assembly clarified the August 4th decree to assure that "legitimate" seigneurial property rights were maintained. While personal feudal servitudes such as hunting rights, seigneurial justice, and labour services were suppressed outright, most seigneurial dues were to be abolished only if the peasants paid compensation to their lords, set at 20 to 25 times the annual value of the obligation. The vast majority of peasants rejected that requirement by passive resistance, until pressure built in 1792–93 for the complete abolition of all seigneurial dues without compensation.

The abolition of feudalism was crucial to the evolution of a modern, contractual notion of property and to the development of an unimpeded market in land. But it did not directly affect the ownership of land or the level of ordinary rents and leases. Seigneurs lost certain kinds of traditional income, but they remained landowners and landlords. While all peasants gained in dignity and status, only the landowning peasants came out substantially ahead economically. Tenant farmers found that what they had once paid for the tithe was added on to their rent. And the Assembly did virtually nothing to assure better lease terms for renters and sharecroppers, let alone their acquisition of the land they tilled.

Declaration of the Rights of Man and of the Citizen

The new regime. By sweeping away the old web of privileges, the August 4th decree permitted the Assembly to construct a new regime. Since it would take months to draft a constitution, the Assembly on August 27 promulgated its basic principles in a Declaration of the Rights of Man and of the Citizen. A rallying point for the future, the declaration also stood as the death certificate of the ancien régime. The declaration's authors believed it to have universal significance. "In the new hemisphere, the brave inhabitants of Philadelphia have given the example of a people who reestablished their liberty," conceded one deputy, but "France would give that example to the rest of the world." At the same time the declaration responded to particular circumstances and was thus a calculated mixture of general principles and specific concerns. Its concept of natural rights meant that the Revolution would not be bound by history and tradition but could reshape the contours of society according to reason—a position vehemently denounced by Edmund Burke in England.

The very first article of the declaration resoundingly challenged Europe's old order by affirming that "men are born and remain free and equal in rights. Social distinctions may be based only on common utility." Most of its articles concerned individual liberty, but the declaration's emphasis fell equally on the prerogatives of the state as expressed through law. (Considering how drastically the erstwhile delegates to the Estates-General had exceeded their mandates, they certainly needed to underscore the legitimacy of their new government and its laws.) The declaration, and subsequent revolutionary constitutions, channeled the sovereignty of the nation into representative government, thereby negating claims by *parlements,* provincial estates, or divine-right monarchs as well as any conception of direct democracy. Though the declaration affirmed the separation of powers, by making no provision for a supreme court, it effectively left the French legislature as the ultimate judge of its own actions. The declaration defined liberty as "the ability to do whatever does not harm another . . . whose limits can only be determined by law." The same limitation by positive law was attached to specific liberties, such as freedom from arbitrary arrest, freedom of expression, and freedom of religious conscience. The men of 1789 believed deeply in these liberties, yet they did not establish them in autonomous, absolute terms that would insure their sanctity under any circumstances.

The constitution

Restructuring France. From 1789 to 1791 the National Assembly acted as a constituent assembly, drafting a constitution for the new regime while also governing from day to day. The constitution established a limited monarchy, with a clear separation of powers in which the king was to name and dismiss his ministers. But sovereignty effectively resided in the legislative branch, to consist of a single house, the Legislative Assembly, elected by a system of indirect voting. ("The people or the nation can have only one voice, that of the national legislature," wrote Sieyès. "The people can speak and act only through its representatives.") Besides failing to win a bicameral system, the moderate Anglophile, or *monarchien,* faction lost a bitter debate on the king's veto power: the Assembly granted the king only a suspensive or delaying veto over legislation; if a bill passed the Legislative Assembly in three successive years, it would become law even without royal approval.

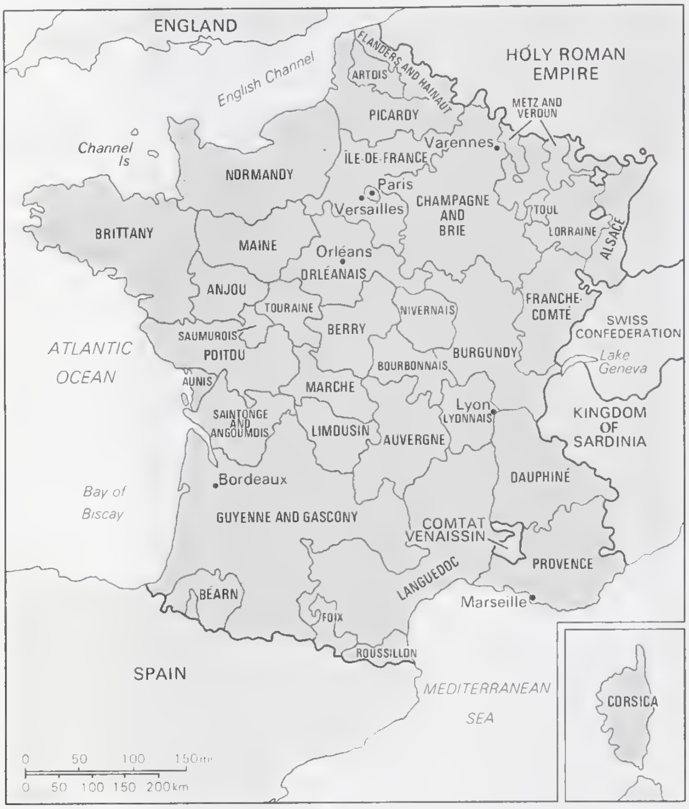
Dismayed at what he deemed the ill-considered radicalism of such decisions, Jean-Joseph Mounier, a leading patriot deputy in the summer of 1789 and author of the Tennis Court Oath, resigned from the Assembly in October. In a similar vein, some contemporary historians (notably François Furet) have suggested that the Assembly's integral concept of national sovereignty and legislative supremacy effectively reestablished absolutism in a new guise, providing the new government with inherently unlimited powers. Nor, they believe, is it surprising that the revolutionaries abused those powers as their pursuit of utopian goals encountered resistance. In theory this may well be true, but it must be balanced against the actual institutions created to implement those powers and the spirit in which they were used. With a few exceptions—notably the religious issue—the National Assembly acted in a liberal spirit, more pragmatic than utopian, and was decidedly more constructive than repressive.

The revolutionaries took civil equality seriously but created a limited definition of political rights. They effectively transferred political power from the monarchy and the privileged estates to the general body of propertied citizens. Nobles lost their privileges in 1789 and their titles in 1790, but as propertied individuals they could readily join the new political elite. The constitution restricted the franchise to "active" citizens who paid a minimal sum in taxes, with higher property qualifications for eligibility for public office (a direct tax payment equivalent to three days' wages for voting and 10 days' wages for electors and officeholders). Under this system about two-thirds of adult males had the right to vote for electors and to choose certain local officials directly. Although it favoured wealthier citizens, the system was vastly more democratic than Britain's.

Women's rights and roles

Predictably, the franchise did not extend to women, despite delegations and pamphlets advocating women's rights. The Assembly responded brusquely that, because women were too emotional and easily misled, they must be kept out of public life and devote themselves to their nurturing and maternal roles. But the formal exclusion of women from politics did not keep them on the sidelines. Women were active combatants in local conflicts that soon erupted over religious policy, and they agitated over subsistence issues—Parisian women, for example, made a mass march to Versailles in October that forced the king to move back to the capital. In the towns, they formed auxiliaries to local Jacobin clubs and even a handful of independent women's clubs, participated in civic festivals, and did public relief work.

The Assembly's design for local government and administration proved to be one of the Revolution's most durable legacies. Obliterating the political identity of France's historic provinces, the deputies redivided the nation's territory into 83 *départements* of roughly equal size. Unlike the old provinces, each department would have exactly



Gouvernements before 1789.

the same institutions; departments were in turn subdivided into districts, cantons, and communes (the common designation for a village or town). On the one hand, this administrative transformation promoted decentralization and local autonomy: citizens of each department, district, and commune elected their own local officials. On the other hand, these local governments were subordinated to the national legislature and ministries in Paris. The departments therefore became instruments of national uniformity and integration, which is to say, centralization. This ambiguity the legislators fully appreciated, assuming that a healthy equilibrium could be maintained between the two tendencies. That the revolutionary government of 1793 and Napoleon later used these structures to concentrate power from the centre was not something they could anticipate.

The new administrative map also created the parameters for judicial reform. Sweeping away the entire judicial system of the ancien régime, the revolutionaries established a civil court in each district and a criminal court in each department. At the grass roots they replaced seigneurial justice with a justice of the peace in each canton. Judges on all these tribunals were to be elected. While rejecting the use of juries in civil cases, the Assembly decreed that felonies would be tried by juries; if a jury convicted, judges would merely apply the mandatory sentences set out in the Assembly's tough new penal code of 1791. Criminal defendants also gained the right to counsel, which had been denied them under the jurisprudence of the ancien régime. In civil law, the Assembly encouraged arbitration and mediation to avoid the time-consuming and costly processes of formal litigation. In general, the revolutionaries hoped to make the administration of justice more accessible and expeditious.

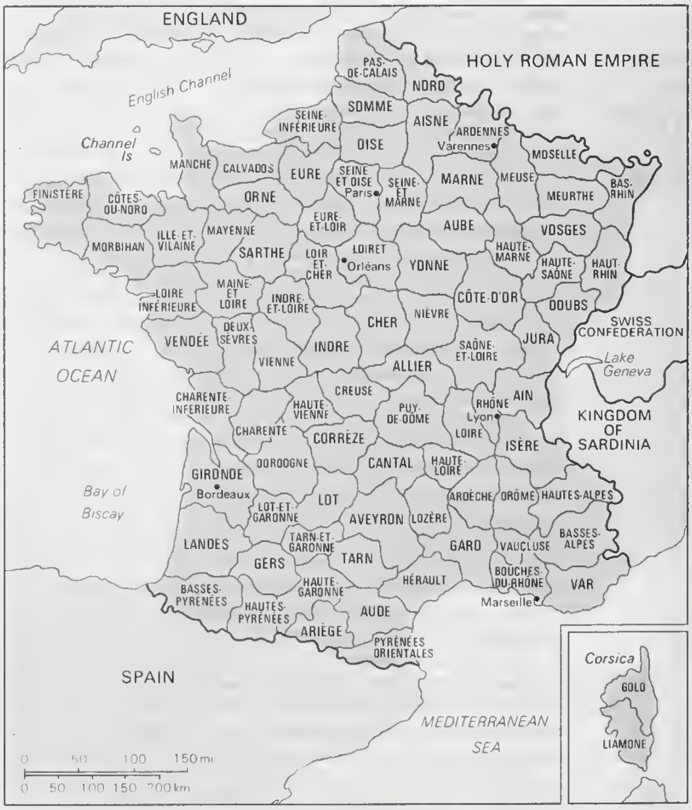
Economic reforms

Guided by laissez-faire doctrine and its hostility to privileged corporations, the Assembly sought to open up economic life to unimpeded individual initiative and competition. Besides proclaiming the right of all citizens to enter any trade and conduct it as they saw fit, the Assembly dismantled internal tariffs and chartered trading monopolies and abolished the guilds of merchants and artisans. Insisting that workers must bargain in the economic marketplace as individuals, the Le Chapelier Law of June 1791 banned workers' associations and strikes. The precepts of economic individualism extended to rural life as well. In theory, peasants and landlords were now free to cultivate their fields as they wished, regardless of traditional collective routines and constraints. In practice, however, communal restraints proved to be deep-rooted and resistant to legal abolition.

Sale of national lands. The Assembly had not lost sight of the financial crisis that precipitated the collapse of absolutism in the first place. Creating an entirely new option for its solution, the Assembly voted to place church property—about 10 percent of the land in France—"at the disposition of the nation." This property was designated as *biens nationaux,* or national lands. The government then issued large-denomination notes called assignats, underwritten and guaranteed by the value of that land. It intended to sell off national lands to the public, which would pay for it in assignats that would then be retired. Thus church property would in effect pay off the national debt and obviate the need for further loans. Unfortunately the temptation to print additional assignats proved too great. Within a year the assignat evolved into a paper currency in small and large denominations, with sharp inflationary effects.

Sale of national lands

As the national lands went on sale, fiscal needs took priority over social policy. Sales were arranged in large lots and at auction in the district capitals—procedures that favoured wealthier buyers. True, for about a year in 1793–94, after émigré property was added to the *biens nationaux,* large lots were divided into small parcels. In addition, small peasants acquired some of this land through resale by the original buyers. But overall the urban middle classes and large-scale peasants emerged with the bulk of this land, to the intense frustration of small peasants. The French historian Georges Lefebvre's study of the Nord department, for example, found that 7,500 bourgeois purchased 48 percent of the land, while 20,300 peasants bought 52 percent. But the top 10 percent of these peasant purchasers accounted for 60 percent of the peasants' total. Whatever the social origins of the buyers, however, they were likely to be reliable supporters of the Revolution if only to guarantee the security of their new acquisitions.



Revolutionary departments after 1789.

Seeds of discord. Security could not be taken for granted, however, because the Revolution progressively alienated or disappointed important elements of French society. Among the elites, opposition began almost immediately when some of the king's close relatives left the country in disgust after July 14, thus becoming the first émigrés. Each turning point in the Revolution touched off new waves of emigration, especially among the nobility. By 1792 an estimated two-thirds of the royal officer corps had resigned their commissions and most had left the country. A contentious royalist press bitterly denounced the policies of the Assembly as spoliation and the revolutionary atmosphere as a form of anarchy. Abroad, widespread enthusiasm for the events in France among the general public from London to Vienna was matched by intense hostility in ruling circles, fearful of revolutionary contagion within their own borders.

After the first months of solidarity, long-standing urban-rural tensions took on new force. Though peasants might vote in large numbers, the urban middle classes predictably emerged with the lion's share of the new district and departmental offices after the first elections of 1790. Administrative and judicial reform gave these local officials more powers for intrusion into rural society than royal officials ever had, with battalions of armed national guards to back them up. Peasants might easily view urban revolutionary elites as battening on political power and national lands. And, while the Assembly made the tax system more uniform and equitable, direct taxes remained heavy and in formerly privileged regions actually rose, while nothing was done to relieve the plight of tenant farmers. Later, when the revolutionary government sought to draft young men into the army, another grievance was added to the list.

The Civil Constitution of the Clergy

Religious tensions. But it was religious policy that most divided French society and generated opposition to the Revolution. Most priests had initially hoped that sweeping reform might return Roman Catholicism to its basic ideals, shorn of aristocratic trappings and superfluous privileges, but they assumed that the church itself would collaborate in the process. In the Assembly's view, however, nationalization of church property gave the state responsibility for regulating the church's temporal affairs, such as salaries, jurisdictional boundaries, and modes of clerical appointment. On its own authority the Assembly reduced the number of dioceses and realigned their boundaries to coincide with the new departments, while requesting local authorities to redraw parish boundaries in conformity with population patterns. Under its Civil Constitution of the Clergy (July 1790) bishops were to be elected by departmental electoral assemblies, while parish priests were to be chosen by electors in the districts. Clerical spokesmen deplored the notion of lay authority in such matters and insisted that the Assembly must negotiate reforms with a national church council.

In November 1790 the Assembly forced the issue by requiring all sitting bishops and priests to take an oath of submission. Those who refused would lose their posts, be pensioned off, and replaced by the prescribed procedures. Throughout France a mere seven bishops complied, while only 54 percent of the parish clergy took the oath. Contrary to the Assembly's hopes, the clergy had split in two, with "constitutional" priests on one side and "refractory" priests on the other. Regional patterns accentuated this division: in the west of France, where clerical density was unusually high, only 15 percent of the clergy complied.

The schism quickly engulfed the laity. As refractories and constitutionals vied for popular support against their rivals, parishioners could not remain neutral. Intense local discord erupted over the implementation of the Civil Constitution of the Clergy. District administrations backed by urban national guards intervened to install "outsiders" chosen to replace familiar or even beloved refractory priests in many parishes; villagers responded by badgering or boycotting the hapless priests who took the oath. Opinion on both sides tended to fateful extremes, linking either the Revolution with impiety or the Roman Catholic church with counterrevolution.

Political tensions. The political life of the new regime was also proving more contentious than the revolutionaries had anticipated. With courage and consistency, the Assembly had provided that officials of all kinds be elected. But it was uncertain whether these officials, once the ballots were cast, could do their duty free from public pressure and agitation. Nor was it clear what the role of "public opinion" and the mechanisms for its expression would be. The spectacular development of a free press and political clubs provided an answer. Fearful that these extraparliamentary institutions could be abused by demagogues, the Assembly tried to curb them from time to time but to no avail. Freed entirely from royal censorship, writers and publishers rushed to satisfy the appetite for news and political opinion. The first journalists included deputies reporting to their constituents by means of a newspaper. Paris, which had only four quasi-official newspapers at the start of 1789, saw more than 130 new periodicals by the end of the year, most admittedly short-lived, including 20 dailies. As the journalist Jacques-Pierre Brissot put it, newspapers are "the only way of educating a large nation unaccustomed to freedom or to reading, yet looking to free itself from ignorance." Provincial publishers were as quick to found new periodicals in the larger towns. Bordeaux, for example, had only one newspaper in 1789, but 16 appeared within the next two years. While some papers remained bland and politically neutral, many had strong political opinions.

Revolutionary clubs

Like the National Assembly, revolutionary clubs also began at Versailles, when patriot deputies rallied to a caucus of outspoken Third Estate deputies from Brittany. This Breton Club, complete with by-laws, minutes, committees, correspondence, and membership requirements, began to call itself "The Society of the Friends of the Constitution." Soon it was known as the Jacobin Club, after the Dominican convent where the club met when the assembly transferred to Paris in October. Most prominent revolutionaries belonged to the Jacobin Club, from constitutional royalists such as Mirabeau, Lafayette, and Barnave to radicals like Brissot, Pétion, and Robespierre. By mid-1791, however, moderates became uncomfortable at the Jacobin Club, where Maximilien Robespierre was emerging as a dominant figure.

The Jacobin Club was pushed from the left by the Cordeliers Club, one of the neighbourhood clubs in the capital. The Cordeliers militants rejected the Assembly's concept of representation as the exclusive expression of popular sovereignty. They held to a more direct vision of popular sovereignty as relentless vigilance and participation by citizens through demonstrations, petitions, deputations, and if necessary insurrection. In his newspaper *L'Ami du peuple* ("The Friend of the People") Jean-Paul Marat injected an extreme rhetoric about alleged conspiracies and the need for violence against counterrevolutionaries that exceeded anything heard in the Assembly's political discourse.

Like the press, clubs quickly spread in the provinces. Building no doubt on old-regime patterns of sociability—reading clubs, Freemasonry, or confraternities—political clubs became a prime vehicle for participation in the Revolution. More than 300 towns had clubs by the end of 1790, and 900 by mid-1791. Later clubs spread to the villages as well: a study has counted 5,000 localities that had clubs at one time or another between 1790 and 1795. Many clubs affiliated with the Paris Jacobin Club, the "mother club," in an informal nationwide network. Most began with membership limited to the middle class and a sprinkling of liberal nobles, but gradually artisans, shopkeepers, and peasants joined the rolls. Initially the clubs promoted civic education and publicized the Assembly's reforms. But some became more activist, seeking to influence political decisions with petitions, to exercise surveillance over constituted authorities, and to denounce those they deemed remiss.

By 1791 the assembly found itself in a cross-fire between the machinations of counterrevolutionaries—émigrés, royalist newspapers, refractory clergy—and the denunciations of radicals. Its ability to steer a stable course depended in part on the cooperation of the king. Publicly Louis XVI distanced himself from his émigré relatives, but privately he was in league with them and secretly corresponded with the royal houses of Spain and Austria to enlist their support. On June 21, 1791, the royal family attempted to flee its "captivity" in the Tuileries Palace and escape across the Belgian border. Rashly, Louis left behind a letter revealing his utter hostility to the Revolution. At the last minute, however, the king was recognized at the town of Varennes near the border, and the royal party was forcibly returned to Paris.

Splitting of the Jacobin Club

A great crisis for the Revolution ensued. While the Assembly reinforced the frontiers by calling for 100,000 volunteers from the national guard, its moderate leaders hoped that this fiasco would end Louis's opposition once and for all. In order to preserve their constitutional compromise, they turned a blind eye to the king's manifest treason by inventing the fiction that he had been kidnapped. As Antoine Barnave put it: "Are we or are we not going to terminate the Revolution? Or are we going to start it all over again?" Outside the Assembly, however, Jacobins and Cordeliers launched a petition campaign against reinstating the king. A mass demonstration on July 17 at the Champ de Mars against the king ended in a bloody riot, as the authorities called out the national guard under Lafayette's command to disperse the demonstrators. This precipitated vehement recriminations in the Jacobin Club, which finally split apart under the pressure. The mass of moderate deputies abandoned the club to a rump of radicals and formed a new association called the Feuillant Club. Under the leadership of Robespierre and Jérôme Pétion (who later became mortal enemies), the purged Jacobin Club rallied most provincial clubs and emerged from the crisis with a more unified, radical point of view. For the time being, however, the moderates prevailed in the Assembly. They completed the Constitution of 1791, and on the last day of September 1791 the National Assembly dissolved itself, having previously decreed the ineligibility of its members for the new Legislative Assembly.

When the newly elected Legislative Assembly convened in October, the question of counterrevolution dominated its proceedings. Jacobin deputies like Brissot argued that only war against the émigré army gathering at Coblenz across the Rhine could end the threat: "Do you wish at one blow to destroy the aristocracy, the refractory priests, and the malcontents: then destroy Coblenz." Whereas the Feuillants opposed this war fever, Lafayette saw a successful military campaign as a way to gain power, while the king's circle believed that war would bring military defeat to France and a restoration of royal authority. On the other side, the Habsburg monarch, Leopold II, had resisted the pleas of his sister Marie-Antoinette and opposed intervention against France, but his death in March 1792 brought his bellicose son Francis II to the throne and the stage was set for war.

The Brunswick Manifesto

In April 1792 France went to war against a coalition of Austria, Prussia, and the émigrés. Each camp expected rapid victory, but both were disappointed. The allies repulsed a French offensive and soon invaded French territory. The Legislative Assembly called for a new levy of 100,000 military volunteers, but, when it voted to incarcerate refractory clergy, the king vetoed the decree. Though many Frenchmen remained respectful of the king, the most vocal elements of public opinion denounced Louis and demonstrated against him; but the Legislative Assembly refused to act. As Prussian forces drove toward Paris, their commander, the Duke of Brunswick, proclaimed his aim of restoring the full authority of the monarchy and warned that any action against the king would bring down "exemplary and memorable vengeance" against the capital. Far from terrifying the Parisians, the Brunswick Manifesto enraged them and drove them into decisive action.

Militants in the Paris Commune, the revolutionary government of Paris set up by the capital's 48 wards or sections, gave the Legislative Assembly a deadline in which to suspend the king. When it passed unheeded, they organized an insurrection. On Aug. 10, 1792, a huge crowd of armed Parisians stormed the royal palace after a fierce battle with the garrison. The Legislative Assembly then had no choice but to declare the king suspended. That night more than half the deputies themselves fled Paris, for the Legislative Assembly too had lost its mandate. Those who remained ordered the election by universal male suffrage of a National Convention. It would judge the king, draft a new republican constitution, and govern France during the emergency. The Constitution of 1791 had lasted less than a year, and the second revolution dreaded by the Feuillants had begun.

THE FIRST FRENCH REPUBLIC

The second revolution. The insurrection of Aug. 10, 1792, did not of course stop the Prussian advance on the capital. As enthusiastic contingents of volunteers left for the front, fear of counterrevolutionary plots gripped the capital. Journalists like Jean-Paul Marat pointed to the prisons bursting with vagrants and criminals as well as refractory clergy and royalists and asked what would happen if traitors forced open the jails and released these hordes of fanatics and brigands. In response Parisians took the law into their own hands with an orgy of mass lynching.

Prison massacres

On their own initiative, citizens entered the prisons, set up "popular tribunals" to hold perfunctory trials, and summarily executed between 1,100 and 1,400 prisoners out of a total of 2,800, stabbing and hacking them to death with any instruments at hand. These prison massacres were no momentary fit of frenzy but went on for four days. At the time no one in authority dared try to stop the slaughter. Officials of the provisional government and the Paris Commune "drew a veil" over this appalling event as it ran its course, though soon political rivals were accusing each other of instigating the massacres. In a different vein, Robespierre among others concluded that popular demands for vengeance and terror had to be channeled into legal forms; to prevent such anarchy, the state itself must become the orderly instrument of the people's punitive will.

The next two weeks brought this period of extreme uncertainty to a close. On September 20 the French army turned back the invaders at the Battle of Valmy, and in November at the Battle of Jemappes it won control of the Austrian Netherlands (now Belgium). On September 21 the National Convention convened, ending the vacuum of authority that had followed the August 10 insurrection. Its first major task was to decide the fate of the ex-king. The Convention's trial of Louis became an educational experience for the French people in which the institution of monarchy was to be completely desacralized.

Execution of Louis Capet

Hard evidence of Louis's treason produced a unanimous guilty verdict, but the issue of punishment divided the deputies sharply. In a painstaking and solemn debate each deputy cast his vote individually and explained it. At the end the Convention voted the death sentence, 387 to 334. A motion for reprieve was defeated (380 to 310), and one to submit the verdict to a national referendum was rejected (425 to 286). This ill-considered proposal left the impression that certain deputies were frantic to save the king's life, and their Jacobin opponents were quick to raise vague accusations of treasonous intent against them. In any event, the former King Louis XVI, now known simply as "Citizen Capet," was executed on Jan. 21, 1793, in an act of immense symbolic importance. For the deputies to the National Convention, now regicides, there could be no turning back. Laws to deport the refractory clergy, to bar the émigrés forever upon pain of death, and to confiscate their property rounded out the Convention's program for eliminating the Revolution's most determined enemies.

A republic in crisis. By the spring of 1793, however, the republic was beleaguered. In the second round of the war, the coalition—now reinforced by Spain, Piedmont, and Britain—routed French forces in the Austrian Netherlands and the Rhineland and breached the Pyrenees. Fighting on five different fronts and bereft of effective leadership, French armies seemed to be losing everywhere. Even General Charles-François Dumouriez, the hero of the first Netherlands campaign, had gone over to the enemy in April after quarreling with the Convention. Meanwhile, civil war had broken out within France. Rural disaffection in western France, especially over the religious question referred to earlier, had been building steadily, leaving republicans in the region's cities and small towns an unpopular and vulnerable minority. Rural rage finally erupted into armed rebellion when in March 1793 the Convention decreed that each department must produce a quota of citizens for the army. In four departments south of the Loire River the Vendée rebellion began with assaults on the towns and the massacre of patriots. Gradually royalist nobles assumed the leadership of the peasants and weavers who had risen on their own initiative. Forging them into a "Catholic and Royalist Army," they hoped to overthrow the republic and restore the Bourbons.

The Convention could take no comfort from the economic situation either. An accelerating depreciation of the assignats compounded severe shortages of grain and flour in 1793. Inflation, scarcity, and hoarding made life unbearable for the urban masses and hampered efforts to provision the republic's armies. In reaction to such economic hardships and to the advance of antirepublican forces at the frontiers and within France, Parisian radicals clamoured relentlessly for decisive action such as price controls and the repression of counterrevolutionaries.

Girondins and Montagnards. The Convention, however, was bitterly divided almost to the point of paralysis. From the opening day, two outspoken groups of deputies vied for the support of their less factional colleagues. The roots of this rivalry lay in a conflict between Robespierre and Brissot for leadership of the Jacobin Club in the spring and summer of 1792. At that time Robespierre had argued almost alone against the war that Brissot passionately advocated. Later, when the war went badly and the Brissotins, anxious to wield executive power, acted equivocally in their relations with the king, the Jacobins turned on them. Brissot was formally expelled from the club in October, but his expulsion merely formalized a division that had already crystallized during the elections to the Convention in the previous month.

The Paris electoral assembly sent Robespierre, Marat, Georges-Jacques Danton, and other stalwarts of the Paris Commune and the Jacobin Club to the Convention, while systematically rejecting Brissot and his allies such as the former mayor of Paris, Pétion. The Parisian deputies and their provincial supporters, numbering between 200 and 300 (depending on which historian's taxonomy one accepts), took seats on the Convention's upper benches and came to be known as the Montagnards, or the Mountain.

Supported by a network of journalists and by politicians such as Interior Minister Jean-Marie Roland, however, the Brissotins retained their popularity in the provinces and were returned as deputies by other departments. In the Convention the Brissotin group included most deputies from the department of the Gironde, and the group came to be known by their opponents as the Girondins. The inner core of this loose faction, who often socialized in Jeanne-Marie Roland's salon, numbered about 60, and with their supporters perhaps 150 to 175.

Differences between Girondins and Montagnards

At bottom the Girondin-Montagnard conflict stemmed from a clash of personalities and ambitions. Over the years, historians have made the case for each side by arguing that their opponents constituted the truly aggressive or obstructive minority seeking to dominate the Convention. Clearly most deputies were put off by the bitter personal attacks that regularly intruded on their deliberations. The two factions differed most over the role of Paris and the best way to deal with popular demands. Though of similar middle-class background as their rivals, the Montagnards sympathized more readily with the sansculottes (the local activists) of the capital and proved temperamentally bolder in their response to economic, military, and political problems. United by an extreme hostility to Parisian militance, the Girondins never forgave the Paris Commune for its inquisitorial activity after August 10. Indeed, some Girondins did not feel physically secure in the capital. They also appeared more committed to political and economic liberties and therefore less willing to adopt extreme revolutionary measures no matter how dire the circumstances. Ready to set aside similar constitutional scruples, the Montagnards tailored their policies to the imperatives of "revolutionary necessity" and unity.

While the Girondins repeatedly attacked Parisian militants—at one point demanding the dissolution of the Paris Commune and the arrest of its leaders—the Montagnards gradually forged an informal alliance with the sansculottes. Similarly, the Montagnards supported deputies sent on mission to the departments when they clashed with locally elected officials, while the Girondins tended to back the officials. The Montagnards therefore alienated many moderate republicans in the provinces. As deputies of the centre, or "Plain," such as Bertrand Barère, vainly tried to mediate between the two sides, the convention navigated through this factionalism as best it could and improvised new responses to the crisis: a revolutionary tribunal to try political crimes; local surveillance committees to seek out subversives; and a Committee of Public Safety to coordinate measures of revolutionary defense. By the end of May 1793 a majority seemed ready to support the Mountain.

Believing that the Girondins had betrayed and endangered the republic, the Paris sections (with the connivance of the Montagnards and the Paris Jacobin Club) demanded in petitions that the Convention expel the "perfidious deputies." On May 31 they mounted a mass demonstration and on June 2 forced a showdown by deploying armed national guards around the convention's hall. Backed by a huge crowd of unarmed men and women, their solid phalanx of fixed bayonets made it impossible for the deputies to leave without risking serious violence. Inside, the Montagnards applauded this insurrection as an expression of popular sovereignty, akin to that of July 14 or August 10. When the people thus spoke directly, they argued, its deputies had no choice but to comply. Centrists did everything they could to avoid a purge but in the end decided that only this fateful act could preserve the Revolution's unity. Barère composed a report to the French people justifying the expulsion of 29 Girondins. Later 120 deputies who signed a protest against the purge were themselves suspended from the Convention, and in October the original Girondins stood trial before the revolutionary tribunal, which sentenced them to death. The Montagnard ascendancy had begun.

Though the deadlock in the Convention was now broken, the balance of forces in the country was by no means clear. The Parisian sansculottes might well continue to intimidate the convention and emerge as the dominant partner in their alliance with the Montagnards—just as Girondin orators had warned. Conversely, provincial opinion might rebel against this mutilation of the National Convention by Paris and its Montagnard partisans. Purged of the Girondins, the Convention itself could reach consensus more readily, but the nation as a whole was more divided than ever.

At first it seemed as if the expulsion of the Girondins would indeed backfire. More than half of the departmental directories protested against the Convention's purge. But, faced with the pleas for unity and the threats from the Convention, most of this opposition subsided quickly. Only 13 departments continued their defiant stance, and only 6 of these passed into overt armed rebellion against the Convention's authority. Still, this was a serious threat in a country already beleaguered by civil war and military reversals. The Jacobins stigmatized this new opposition as the heresy of federalism—implying that the "federalists" no longer believed in a unified republic. Jacobin propaganda depicted the federalists as counterrevolutionaries. In fact, most were moderate republicans hostile to the royalists and committed to constitutional liberties. They did not intend to overthrow the republic or separate from it. Rather they hoped to wrest power back from what they deemed the tyrannical alliance of Montagnards and Parisian sansculottes.

Uprisings in Lyon and Marseille

In Lyon, Marseille, Toulon, and Bordeaux, bitter conflicts between local moderates and Jacobins contributed decisively to the rebellion. Uprisings in Lyon and Marseille (France's second- and third-largest cities) began in late May when moderates seized power from local Jacobin authorities who had threatened their lives and property—Jacobins like the firebrand Marie-Joseph Chalier in Lyon who was supported by Montagnard representatives-on-mission. The expulsion of the Girondins was merely the last straw. Whatever its causes, however, "federalist" rebellion did threaten national unity and the Convention's sovereign authority. Royalists, moreover, did gain control of the movement in Toulon and opened that port to the British. Holding out no offer of negotiation, the Convention organized military force to crush the rebellions and promised the leaders exemplary punishment. "Lyon has made war against liberty," declared the Convention; "Lyon no longer exists." When the republic's forces recaptured the city in October, they changed its name to "Liberated City," demolished the houses of the wealthy, and summarily executed more than 2,000 Lyonnais, including many wealthy merchants.

The Reign of Terror. After their victory in expelling the Girondins, Parisian militants "regenerated" their own sectional assemblies by purging local moderates, while radicals like Jacques-René Hébert and Pierre-Gaspard Chaumette tightened their grip on the Paris Commune. On Sept. 5, 1793, they mounted another mass demonstration to demand that the Convention assure food at affordable prices and "place terror on the order of the day." Led by its Committee of Public Safety, the Convention placated the popular movement with decisive actions. It proclaimed the need for terror against the Revolution's enemies, made economic crimes such as hoarding into capital offenses, and decreed a system of price and wage controls known as the maximum. The Law of Suspects empowered local revolutionary committees to arrest "those who by their conduct, relations or language spoken or written, have shown themselves partisans of tyranny or federalism and enemies of liberty." In 1793–94 well over 200,000 citizens were detained under this law; though most of them never stood trial, they languished in pestiferous jails, where an estimated 10,000 perished. About 17,000 death sentences were handed down by the military commissions and revolutionary tribunals of the Terror, 72 percent for charges of armed rebellion in the two major zones of civil war—the federalist southeast and the western Vendée region. One-third of the departments, however, had fewer than 10 death sentences passed on their inhabitants and were relatively tranquil.

The maximum

To help police the maximum and requisition grain in the countryside, as well as to carry out arrest warrants and guard political prisoners, the Convention authorized local authorities to create paramilitary forces. About 50 such *armées révolutionnaires* came into being as ambulatory instruments of the Terror in the provinces. Fraternizing with peasants and artisans in the hinterland, these forces helped raise revolutionary enthusiasm but ultimately left such village sansculottes vulnerable to the wrath of the wealthy citizens whom they harassed.

Back in June the Convention had quickly drafted a new democratic constitution, incorporating such popular demands as universal male suffrage, the right to subsistence, and the right to free public education. In a referendum this Jacobin constitution of 1793 was approved virtually without dissent by about two million voters. Because of the emergency, however, the Convention placed the new constitution on the shelf in October and declared that "the provisional government of France is revolutionary until the peace." There would be no elections, no local autonomy, no guarantees of individual liberties for the duration of the emergency. The Convention would rule with a sovereignty more absolute than the old monarchy had ever claimed. Nor would serious popular protest be tolerated any longer, now that the Jacobins had used such intervention to secure power. The balance in the alliance between Montagnards and sansculottes gradually shifted from the streets of Paris to the halls and committee rooms of the Convention.

The Jacobin constitution

From the beginning a popular terrorist mentality had helped shape the Revolution. Peasants and townspeople alike had been galvanized by fear and rage over "aristocratic plots" in 1789. Lynchings of "enemies of the people" punctuated the Revolution, culminating in the September massacres, which reflected an extreme fear of betrayal and an unbridled punitive will. Now the Revolution's leaders were preempting this punitive will in order to control it: they conceived of terror as rational rather than emotional and as organized rather than instinctive. Paradoxically they were trying to render terror lawful—legality being an article of faith among most revolutionaries—but without the procedural safeguards that accompanied the regular criminal code of 1791.

For the more pragmatic Montagnards that deviation was justified by the unparalleled emergency situation confronting France in 1793: before the benefits of the Revolution could be enjoyed, they must be secured against their enemies by force. ("Terror is nothing other than justice, prompt, severe, inflexible . . . . Is force made only to protect crime?" declared Robespierre.) For the more ideologically exalted Jacobins like Robespierre and Saint-Just, however, the terror would also regenerate the nation by promoting equality and the public interest. In their minds a link existed between terror and virtue: "virtue, without which terror is fatal; terror, without which virtue is powerless." Whoever could claim to speak for the interests of the people held the mantle of virtue and the power of revolutionary terror.

The Jacobin dictatorship. The Convention consolidated its revolutionary government in the Law of 14 Frimaire Year II (Dec. 4, 1793; for a discussion of the Revolutionary calendar, see below). To organize the Revolution, to promote confidence and compliance, efficiency and control, this law centralized authority in a parliamentary dictatorship, with the Committee of Public Safety at the helm. The committee already controlled military policy and patronage; henceforth local administrators (renamed national agents), tribunals, and revolutionary committees also came under its scrutiny and control. The network of Jacobin clubs was enlisted to monitor local officials, nominate new appointees, and in general to serve as "arsenals of public opinion."

The Committee of Public Safety

Opposed to "ultrarevolutionary" behaviour and uncoordinated actions even by its own deputies-on-mission, the committee tried to stop the dechristianization campaigns that had erupted during the anarchic phase of the Terror in the fall of 1793. Usually instigated by radical deputies, the dechristianizers vandalized churches or closed them down altogether, intimidated constitutional priests into resigning their vocation, and often pressured them into marrying to demonstrate the sincerity of their conversion. Favouring a diestic form of civil religion, Robespierre implied that the atheism displayed by some dechristianizers was a variant of counterrevolution. He insisted that citizens must be left free to practice the Roman Catholic religion, though for the time being most priests were not holding services.

The committee also felt strong enough a few months later to curb the activism of the Paris sections, dissolve the *armées révolutionnaires,* and purge the Paris Commune—ironically what the Girondins had hoped to do months before. But in this atmosphere no serious dissent to official policy was tolerated. The once vibrant free press had been muzzled after the purge of the Girondins. In March 1794 Hébert and other "ultrarevolutionaries" were arrested, sent to the revolutionary tribunal, and guillotined. A month later Danton and other so-called "indulgents" met the same fate for seeking to end the Terror—prematurely in the eyes of the committee. Then the Convention passed the infamous law of 22 Prairial Year II (June 10, 1794) to streamline revolutionary justice, denying the accused any effective right to self-defense and eliminating all sentences other than acquittal or death. Indictments by the public prosecutor, now virtually tantamount to a death sentence, multiplied rapidly.

The Terror was being escalated just when danger no longer threatened the republic—after French armies had prevailed against Austria at the decisive Battle of Fleurus on June 26 and long after rebel forces in the Vendée, Lyon, and elsewhere had been vanquished. By June 1794 the Jacobin dictatorship had forged an effective government and had mobilized the nation's resources, thereby mastering the crisis that had brought it into being. Yet, on 8 Thermidor, Robespierre took the rostrum to proclaim his own probity and to denounce yet another unnamed group as traitors hatching "a conspiracy against liberty." Robespierre had clearly lost his grip on reality in his obsession with national unity and virtue. An awkward coalition of moderates, Jacobin pragmatists, rival deputies, and extremists who rightly felt threatened by the Incorruptible

Fall of Robespierre

(as he was known) finally combined to topple Robespierre and his closest followers. On 9 Thermidor (July 27, 1794) the Convention ordered the arrest of Robespierre and Saint-Just, and, after a failed resistance by loyalists in the Paris Commune, they were guillotined without trial the following day. The Terror was over.

The Army of the Republic. The Jacobin dictatorship had been an unstable blend of exalted patriotism, resolute political leadership, ideological fanaticism, and populist initiatives. The rhetoric and symbolism of democracy constituted a new civic pedagogy, matched by bold egalitarian policies. The army was a primary focal point of this democratic impetus. Back in 1790 the National Assembly had opted for a small military of long-term professionals. One-year volunteers bolstered the line army after the outbreak of war, and in March 1793 the convention called for an additional 300,000 soldiers, with quotas to be provided by each department. Finally, in August 1793 it decreed the *lévee en masse*—a "requisition" of all able-bodied, unmarried men between the ages of 18 and 25. Despite massive draft evasion and desertion, within a year almost three-quarters of a million men were under arms, the citizen-soldiers merged with line-army troops in new units called demibrigades. This huge popular mobilization reinforced the revolution's militant spirit. The citizen-soldiers risking their lives at the front had to be supported by any and all means back home, including forced loans on the rich and punitive vigilance against those suspected of disloyalty.

Within the constraints of military discipline, the army became a model of democratic practice. Both noncommissioned and commissioned officers were chosen by a combination of election and appointment, in which seniority received some consideration, but demonstrated talent on the battlefield brought the most rapid promotion. The republic insisted that officers be respectful toward their men and share their privations. Jacobin military prosecutors enforced the laws against insubordination and desertion but took great pains to explain them to the soldiers and to make allowances for momentary weakness in deciding cases. Soldiers received revolutionary newspapers and sang revolutionary songs, exalting the citizen-soldier as the model sansculotte. Meanwhile, needy parents, wives, or dependents of soldiers at the front received subsidies, while common soldiers seriously wounded in action earned extremely generous veterans' benefits.

The Revolution's egalitarian promise never involved an assault on private property, but its concept of "social limitations" on property made it possible for the Convention to abolish all seigneurial dues without compensation, abolish slavery in the colonies (where slave rebellions had already achieved that result in practice), endorse the idea of progressive taxation, and temporarily regulate the economy in favour of consumers. In 1793–94 the Convention enacted an unprecedented national system of public assistance entitlements, with one program allocating small pensions to poor families with dependent children and another providing pensions to aged and indigent farm workers, artisans, and rural widows—the neediest of the needy. "We must put an end to the servitude of the most basic needs, the slavery of misery, that most hideous of inequalities," declared Bertrand Barère of the Committee of Public Safety. The Convention also implemented the Revolution's long-standing commitment to primary education with a system of free public primary schooling for both boys and girls. The Lakanal Law of November 1794 authorized public schools in every commune with more than 1,000 inhabitants, the teachers to be selected by examination and paid fixed salaries by the government.

The Thermidorian reaction. With control passing from the Montagnards after Robespierre's fall, moderates in the convention hoped to put the Terror and sansculotte militance behind them while standing fast against counterevolution and rallying all patriots around the original principles of the Revolution. But far from stabilizing the Revolution, the fall of "the tyrant" on 9 Thermidor set in motion a brutal struggle for power. Those who had suffered under the Terror now clamoured for retribution, and moderation quickly gave way to reaction. As federalists were released, Jacobins were arrested; as the suspended Girondins were reinstated, Montagnards were purged; as moderates could feel safe, Jacobins and sansculottes were threatened. Like the Terror, the Thermidorian reaction had an uncontrollable momentum of its own. Antiterrorism—in the press, the theatre, the streets—degenerated into a "white terror" against the men of the Year II. In the south, especially in Provence and the Rhône valley, the frontier between private feuds and political reaction blurred as law and order broke down. Accounts were settled by lynchings, murder gangs, and prison massacres of arrested sansculottes.

"White terror"

Alongside this political reaction, Thermidor set off a new economic and monetary crisis. Committed to free-trade principles, the Thermidorians dismantled the economic regulation and price controls of the Year II, along with the apparatus of the Terror that had put teeth into that system. The depreciation of the assignats, which the Terror had halted, quickly resumed. By 1795 the cities were desperately short of grain and flour, while meat, fuel, dairy products, and soap were entirely beyond the reach of ordinary consumers. By the spring of 1795 scarcity was turning into famine for working people of the capital and other cities. Surviving cadres of sansculottes in the Paris sections mobilized to halt the reaction and the economic catastrophe it had unleashed. After trying petitions and demonstrations, a crowd of sansculottes invaded the Convention on 1 Prairial Year III (May 20, 1795) in what was to prove the last popular uprising of the French Revolution. "Bread is the goal of their insurrection, physically speaking," reported a police observer, "but the Constitution of 1793 is its soul." This rear-guard rebellion of despair was doomed to fail, despite the support of a few remaining Montagnard deputies, whose fraternization with the demonstrators was to cost them their lives after the insurgents were routed the following day.

Instead of implementing the democratic Constitution of 1793, the Thermidorian Convention was preparing a new, more conservative charter. Anti-Jacobin and antiroyalist, the Thermidorians clung to the elusive centre of the political spectrum. Their constitution of 1795 (Year III) established a liberal republic with a franchise based on the payment of taxes similar to that of 1791, a two-house legislature to slow down the legislative process, and a five-man executive Directory to be chosen by the legislature. Within a liberal framework, the central government retained great power, including emergency powers to curb freedom of the press and freedom of association. Departmental and municipal administrators were to be elected but could be removed by the Directory, and commissioners appointed by the Directory were to monitor them and report on their compliance with the laws.

The Thermidorian constitution

The Directory. The new regime, referred to as the Directory, began auspiciously in October 1795 with a successful constitutional plebiscite and a general amnesty for political prisoners. But as one of its final acts the Convention added the "Two-thirds Decree" to the package, requiring for the sake of continuity that two-thirds of its deputies must sit by right in the new legislature regardless of voting in the departments. This outraged conservatives and royalists hoping to regain power legally, but their armed uprising in Paris was easily suppressed by the army. The Directory also weathered a conspiracy on the far left by a cabal of unreconciled militants organized around a program of communistic equality and revolutionary dictatorship. The Babeuf plot was exposed in May 1796 by a police spy, and a lengthy trial ensued in which François-Noël ("Gracchus") Babeuf, the self-styled "Tribune of the People," was sentenced to death.

Apart from these conspiracies, the political life of the Directory revolved around annual elections to replace one-third of the deputies and local administrators. The spirit of the "Two-thirds Decree" haunted this process, however, since the directors believed that stability required their continuation in power and the exclusion of royalists or Jacobins. The Directory would tolerate no organized opposition. During or immediately after each election, the government in effect violated the constitution in order to save it, whenever the right or the left seemed to be gaining ground.

Elections and coups

As a legacy of the nation's revolutionary upheavals, elections under the Directory displayed an unhealthy combination of massive apathy and rancorous partisanship by small minorities. When the elections of 1797 produced a royalist resurgence, the government responded with the coup of Fructidor Year V (September 1797), ousting two of the current directors, arresting leading royalist politicians, annulling the elections in 49 departments, shutting down the royalist press, and resuming the vigorous pursuit of returned émigrés and refractory clergy. This heartened the Neo-Jacobins, who organized new clubs called "constitutional circles" to emphasize their adherence to the regime. But this independent political activism on the left raised the spectre of 1793 for the Directory, and in turn it closed down the Neo-Jacobin clubs and newspapers, warned citizens against voting for "anarchists" in the elections of 1798, and promoted schisms in electoral assemblies when voters spurned this advice. When democrats (or Neo-Jacobins) prevailed nonetheless, the Directory organized another purge in the coup of Floréal Year VI (May 1798) by annulling all or some elections in 29 departments. Ambivalent and faint-hearted in its republican commitment, the Directory was eroding political liberty from within. But as long as the Constitution of 1795 endured, it remained possible that political liberty and free elections might one day take root.

Sister republics. Meanwhile the Directory regime successfully exported revolution abroad by helping to create "sister republics" in western Europe. During the Revolution's most radical phase, in 1793–94, French expansion had stopped more or less at the nation's self-proclaimed "natural frontiers"—the Rhine, Alps, and Pyrenees. The Austrian Netherlands (now Belgium) and the left bank of the Rhine had been major battlefields in the war against the coalition, and French victories in those sectors were followed by military occupation, requisitions, and taxation, but also by the abolition of feudalism and similar reforms. In 1795 both areas were annexed to France, and their territories were divided into departments, which would henceforth be treated like other French departments.

Strategic considerations and French national interest were the main engines of French foreign policy in the revolutionary decade but not the only ones. Elsewhere in Europe native patriots invited French support against their own ruling princes or oligarchies. As the historian R.R. Palmer has argued, Europe was divided not simply by a conflict between Revolutionary France and other states but by conflicts within various states between revolutionary or democratic forces and conservative or traditional forces. Indeed, abortive revolutionary movements had already occurred in the Austrian Netherlands and in the United Provinces (Dutch Netherlands). The ideals of liberty, equality, or popular sovereignty knew no borders.

By 1797 Prussia and Spain had made peace with France, but Austria and Britain continued the struggle. In a new strategy the French launched an attack across the Alps aimed at Habsburg Lombardy, from which they hoped to drive north toward Vienna. Commanded by General Napoleon Bonaparte, this campaign succeeded beyond expectations. In the process northern Italy was liberated from Austria, and the Habsburgs were driven to the peace table, where they signed the Treaty of Campo Formio on Oct. 17, 1797. An invasion of the Netherlands, home base of British forces on the Continent, produced a similar victory. In short order two "sister republics" were proclaimed by native revolutionaries under French protection—the Cisalpine Republic in northern Italy and the Batavian Republic (formerly the Dutch Netherlands). These were later joined by the Helvetic Republic in Switzerland, and two very shaky republics—the Roman Republic in central Italy and the Parthenopean Republic in the south around Naples. All these republics were exploited financially by the French, but then again their survival depended on the costly presence of French troops. The French interfered in their internal politics, but this was no more than the Directory was doing at home. Because these republics could not defend themselves in isolation, they acted as sponges on French resources as much as they provided treasure or other benefits to France. France's extended lines of occupation made it extremely vulnerable to attack when Britain organized a second coalition in 1798 that included Russia and Austria. But, when the battles were over, Switzerland, northern Italy, and the Netherlands remained in the French sphere of influence.

The treasure coming from the sister republics was desperately needed in Paris since French finances were in total disarray. The collapse of the assignats and the hyperinflation of 1795–96 not only destroyed such social programs as public assistance pensions and free public schooling but also strained the regime's capacity to keep its basic institutions running. In 1797 the government finally engineered a painful return to hard currency and in effect wrote down the accumulated national debt by two-thirds of its value in exchange for guaranteeing the integrity of the remaining third.

Alienation and coups. After the Fructidor coup of 1797 the Directory imprudently resumed the republic's assault on the Roman Catholic religion. Besides prohibiting the outward signs of Catholicism such as the ringing of church bells or the display of crosses, the government revived the Revolutionary calendar. Instituted in 1793, the new calendar featured a 10-day week called the *décade,* designed to swallow up the Christian Sunday in a new cycle of work and recreation. While it had fallen into disuse after the Thermidorian reaction, the Directory ordered in 1798 that the *décadi* be treated as the official day of rest for workers and businesses as well as public employees and schoolchildren. Forbidding organized recreation on Sundays, the regime also pressured Catholic priests to celebrate mass on the *décadi* rather than on ex-Sundays. This aggressive confrontation with the habits and beliefs of most French citizens sapped whatever shreds of popularity the regime still had.

The revolutionary calendar

French citizens were already alienated by the Directory's foreign policy and its new conscription law. Conscription became a permanent obligation of young men between the ages of 20 and 25 under the Loi Jourdan of Sept. 5, 1798. To fight the War of the Second Coalition that began in 1799, the Directory mobilized three "classes," or age cohorts, of young men but encountered massive draft resistance and desertion in many regions. Meanwhile, retreating armies in the field lacked rations and supplies because, it was alleged, corrupt military contractors operated in collusion with government officials. This war crisis prompted the legislature to oust four of the directors (the Prairial coup of June 18, 1799) and allowed a brief resurgence of Neo-Jacobin agitation for drastic emergency measures.

In reality the balance of power was swinging toward a group of disaffected conservatives. Led by Sieyès, one of the new directors, these "revisionists" wished to escape from the instability of the Directory regime, especially its tumultuous annual elections and its cumbersome separation of powers. They wanted a more reliable structure of political power, which would allow the new elite to govern securely and thereby guarantee the basic reforms and property rights of 1789. Ironically, the Neo-Jacobins, or democrats, stood as the constitution's most ardent defenders against the maneuvers of these "oligarchs."

Using mendacious allegations about Neo-Jacobin plots as a cover, the revisionists prepared a parliamentary coup to jettison the constitution. To provide the necessary military insurance, the plotters sought a leading general. Though he was not their first choice, they eventually enlisted Napoleon Bonaparte—recently returned from his Egyptian campaign, about whose disasters the public knew almost nothing. Given a central role in the coup, which occurred on the 18th Brumaire Year VIII (Nov. 9, 1799), General Bonaparte addressed the legislature, and when some deputies balked at his call for scrapping the constitution, his troopers cleared the hall. A rump of each house then convened to draft a new constitution, and during these deliberations Bonaparte shouldered aside Sieyès and emerged as the dominant figure in the new regime. Brumaire was not really a military coup and did not at first produce a dictatorship. It was a parliamentary coup to create a new constitution and was welcomed by people of differing opinions who saw in it what they wished to see.

The Brumaire coup

The image of an energetic military hero impatient with the abuses of the past must have seemed reassuring.

THE NAPOLEONIC ERA

The Consulate. The "revisionists" who engineered the Brumaire coup intended to create a strong, elitist government that would curb the republic's political turmoil and guarantee the conquests of 1789. They had in mind what might be called a senatorial oligarchy rather than a personal dictatorship. General Bonaparte, however, advocated a more drastic concentration of power. Within days of the coup, Bonaparte emerged as the dominant figure, an insistent and persuasive presence who inspired confidence. Clearly outmaneuvered, Sieyès soon withdrew from the scene, taking with him his complex notions of checks and balances. While the regime, known as the Consulate, maintained a republican form, Bonaparte became from its inception a new kind of authoritarian leader.

Emperor Napoleon

Approved almost unanimously in a plebiscite by three million votes (of which half may have been manufactured out of thin air), the Constitution of the Year VIII created an executive consisting of three consuls, but the First Consul wielded all real power. That office was of course vested in Napoleon Bonaparte. In 1802, after a string of military and diplomatic victories, another plebiscite endowed him with the position for life. By 1804 Bonaparte's grip on power was complete, and belief in his indispensability was pervasive in the governing class. In April 1804 various government bodies agreed "that Napoleon Bonaparte be declared Emperor and that the imperial dignity be declared hereditary in his family." The Constitution of the Year XII (May 1804) establishing the empire was approved in a plebiscite by more than 3,500,000 votes against about 8,000. (After this point General Bonaparte was known officially as Napoleon.)

The Constitution of 1791, the Convention, and the Directory alike had been organized around representation and legislative supremacy, the fundamental political principles first proclaimed in June 1789 by the National Assembly. This tradition came to an end with the Consulate. Its new bicameral legislature lost the power to initiate legislation; now the executive branch drafted new laws. One house (the Tribunate) debated such proposals, either endorsed or opposed them, and then sent deputies to present its opinion to the other house, the Legislative Corps (Corps Législatif), which also heard from government spokesmen. Without the right to debate, the Legislative Corps then voted on whether to enact the bill. Even these limited powers were rarely used independently, since both houses were appointed in the first instance by the government and later renewed by cooption. When certain tribunes such as Benjamin Constant did manifest a critical spirit, they were eventually purged, and in 1807 the Tribunate was suppressed altogether. On the whole, then, the legislative branch of government became little more than a rubber stamp.

The Council of State

After Brumaire, Sieyès had envisaged an independent institution called the Senate to conserve the constitution by interpreting it in the light of changing circumstances. In practice, the Senate became the handmaiden of Bonaparte's expanding authority, sanctioning changes such as the life consulship, the purge of the Tribunate, and Napoleon's elevation to the rank of hereditary emperor. For creating "legislation above the laws" at Bonaparte's behest, its 80 handpicked members were opulently rewarded with money and honours. As power shifted decisively to the executive branch, Bonaparte enlisted a new institution called the Council of State to formulate policy, draft legislation, and supervise the ministries. Appointed by the First Consul, this body of experienced jurists and legislators was drawn from across the former political spectrum. Talent and loyalty to the new government were the relevant criteria for these coveted posts.

The Consulate did not entirely eliminate the electoral principle from the new regime, but voters were left with no real power, and elections became an elaborate charade. Citizens voted only for electoral colleges, which in turn created lists of candidates from which the government might fill occasional vacancies in the Legislature or Senate. In the event, the primary assemblies of voters were rarely convened, and membership in the electoral colleges became a kind of honorific lifetime position. The judiciary too lost its elective status. In the hope of creating a more professional and compliant judiciary, the Consulate's sweeping judicial reform provided for lifetime appointments of judges—which did not prevent Napoleon from purging the judiciary in 1808. Napoleon was also disposed to eliminate criminal juries as well, but the Council of State prevailed on him to maintain them.

The prefects

Successive Revolutionary regimes had always balanced local elections with central control, but the Consulate destroyed that balance completely. The Local Government Act of February 1800 eliminated elections for local office entirely and organized local administration from the top down. To run each department, the Consulate appointed a prefect, reminiscent of the old royal intendants, who was assisted by subprefects on the level of the arrondissements (subdistricts of the departments) and by appointed mayors in each commune. The original Revolutionary commitment to local autonomy gave way before the rival principles of centralization and uniformity. The prefect became the cornerstone of the Napoleonic dictatorship, supervising local government at all levels, keeping careful watch over his department's "public spirit," and above all assuring that taxes and conscripts flowed in smoothly. While even the most trivial local matter had to be referred to the prefect, all major decisions taken by the prefect had in turn to be sanctioned by the interior ministry in Paris.

Loss of political freedom. Politics during the Directory had been marked by an unwholesome combination of ferocious partisanship and massive apathy. Weary of political turmoil and disillusioned by politicians of all kinds, most Frenchmen now accepted the disappearance of political freedom and participation with equanimity. The few who still cared passionately enough to resist collided with the apparatus of a police state. A regime that entirely avoided genuine elections would scarcely permit open political dissent. Where the Directory had been ambivalent about freedom of association, for example, the Consulate simply banned political clubs outright and placed Jacobin and royalist cadres under surveillance by the police ministry. In 1801, blaming democratic militants for a botched attempt to assassinate him with a bomb as his carriage drove down the Rue Saint-Nicaise—a plot actually hatched by fanatical royalists—Bonaparte ordered the arrest and deportation to Guiana of about 100 former Jacobin and sansculotte militants. In 1804 he had the Duke d'Enghien, a member of the Bourbon family, abducted from abroad, convicted of conspiracy by a court-martial, and executed.

Reimposition of censorship

Outspoken liberals also felt the lash of Bonaparte's intolerance for any kind of opposition. After he purged the Tribunate, the consul registered his displeasure with the salon politics of liberal intellectuals by dissolving the Class of Moral and Political Science of the National Institute in 1803. One of the most principled liberals, Madame de Stäel, chose to go into exile rather than exercise the self-censorship demanded by the regime. Meanwhile, the only newspapers tolerated were heavily censored. Paris, for example, had more than 70 newspapers at the time of the Brumaire coup; by 1811 only four quasi-official newspapers survived, ironically the same number as had existed before 1789. In the provinces each department had at most one newspaper, likewise of quasi-official character. The reimposition of censorship was matched by Napoleon's astute management of news and propaganda.

Society in Napoleonic France. *Religious policy.* If the Consulate's motto was "authority from above, confidence from below," Bonaparte's religious policy helped secure that confidence. The concordat negotiated with the papacy in 1802 reintegrated the Roman Catholic church into French society and ended the cycle of bare toleration and persecution that had begun in 1792. Having immediately halted the campaign to enforce the republican calendar (which was quietly abolished in 1806), the Consulate then extended an olive branch to the refractory clergy. The state continued to respect the religious freedom of non-Catholics, but the concordat recognized Catholicism as "the preferred religion" of France—in effect, though not in name, the nation's established religion. Upkeep of the church became a significant item in local budgets, and the clergy regained de facto control over primary education. The state, however, retained the upper hand in church-state relations. By signing the concordat, the pope accepted the nationalization of church property in France and its sale as *biens nationaux*. Bishops, though again consecrated by Rome, were named by the head of state, and the government retained the right to police public worship.

The most conservative Catholics looked askance at the concordat, which in their eyes promoted an excessively national or Gallican church rather than a truly Roman Catholic church. They correctly suspected that Bonaparte—personally a religious skeptic—would use it as a tool of his own ambitions. Indeed, he declared that the clergy would be his "moral prefects," propagating traditional values and obedience to authority. Later, for example, the clergy was asked to teach an imperial catechism, which would "bind the consciences of the young to the august person of the Emperor."

Calvinists and Jews

The Napoleonic regime also organized France's approximately one million Calvinists into hierarchical "consistories" subject to oversight by the state. Protestant pastors, paid by the state, were designated by the elders who led local congregations and consistories; the more democratic tendencies of Calvinism were thus weakened in exchange for official recognition. France's 60,000 Jews, residing mainly in Alsace and Lorraine, were also organized into consistories. Like priests and pastors, their rabbis were enlisted to promote obedience to the laws, though they were not salaried by the state. Official recognition, however, did not prevent discriminatory measures against Jews. A law of 1808, ostensibly for "the social reformation of the Jews," appeased peasant debtors in Alsace by canceling their debts to Jewish moneylenders.

Napoleonic nobility. Napoleon cultivated the loyalty of the nation's wealthy landed proprietors by a system of patronage and honours. He thereby facilitated the emergence of a ruling class drawn from both the middle classes and the nobility of the old regime, which had been divided by the artificial barriers of old-regime estates and privileges. The principal artifacts of Napoleon's social policy were the lists he ordered of the 600 largest taxpayers in each department, most having incomes of at least 3,000 livres a year. Inclusion on these lists became an insignia of one's informal status as a notable. Members of the electoral colleges and departmental advisory councils were drawn from these lists. Although such honorific positions had little power and no privileges, the designees were effectively co-opted into the regime. Napoleon's Legion of Honour, meanwhile, conferred recognition on men who served the state, primarily military officers who largely stood outside the ranks of the landed notables. By 1814 the Legion had 32,000 members, of whom only 1,500 were civilians.

The new nobility

After Napoleon had himself crowned emperor in 1804, he felt the need for a court aristocracy that would lend lustre and credibility to his new image. He also reasoned that only by creating a new nobility based on merit could he displace and absorb the old nobility, which had lost its titles in 1790 but not its pretensions. By 1808 a new hierarchy of titles had been created, which were to be hereditary provided that a family could support its title with a large annual income—30,000 livres, for example, in the case of a count of the empire. To facilitate this, the emperor bestowed huge landed estates and pensions on his highest dignitaries. The Napoleonic nobility, in other words, would be a veritable upper class based on a combination of service and wealth. Predictably, the new nobility was top-heavy with generals (59 percent altogether), but it also included many senators, archbishops, and members of the Council of State; 23 percent of the Napoleonic nobility were former nobles of the ancien régime. These social innovations endured after Napoleon's fall—the Bourbons adopted the system of high-status electoral colleges, maintained the Legion of Honour, and even allowed the Napoleonic nobles to retain their titles alongside the restored old-regime nobility.

The Civil Code. The Napoleonic Civil Code, however, had a far greater impact on postrevolutionary society than did the social innovations. This ambitious work of legal codification, perhaps the crowning glory of the Council of State, consolidated certain basic principles established in 1789: civil equality and equality before the law; the abolition of feudalism in favour of modern contractual forms of property; and the secularization of civil relations. Codification also made it easier to export those principles beyond the borders of France. In the area of family relations, however, the Napoleonic Code was less a codification of revolutionary innovations than a reaction against them. By reverting to patriarchal standards that strengthened the prerogatives of the husband and father, it wiped out important gains that women had made during the Revolution. The code's spirit on this subject was summed up in its statement that "a husband owes protection to his wife; a wife owes obedience to her husband." Wives were again barred from signing contracts without their husbands' consent, and a wife's portion of the family's community property fell completely under her husband's control during his lifetime. The code also curbed the right of equal inheritance, which the Revolution had extended even to illegitimate children, and increased the father's disciplinary control over his children.

Divorce legislation

The code also rolled back the Revolution's extremely liberal divorce legislation. When marriage became a civil rite rather than an obligatory religious sacrament in 1792, divorce became possible for the first time. Divorce could be obtained by mutual consent but also for a range of causes including desertion and simple incompatibility. Under the Napoleonic Code contested divorce was possible only for unusually cruel treatment resulting in grave injury and for adultery on the part of the wife. Faced with an unfaithful husband, however, "the wife may demand divorce on the ground of adultery by her husband [only] when he shall have brought his concubine into their common residence."

Napoleonic policy frequently reacted against the Revolution's liberal individualism. While the regime did not restore the guilds outright, for example, it reimposed restrictive or even monopolistic state regulation on such occupational groups as publishers and booksellers, the Parisian building trades, attorneys, barristers, notaries, and doctors. Napoleon wished to strengthen the ties that bound individuals together, which derived from religion, the family, and state authority. Napoleon's domestic innovations—the prefectorial system, with its extreme centralization of administrative authority; the University, a centralized educational bureaucracy that scrutinized all types of teachers; the concordat with the Vatican that reversed the secularizing tendencies of the Revolution; the Civil Code, which strengthened property rights and patriarchal authority; and the Legion of Honour, which rewarded service to the state—all endured in the 19th century despite a succession of political upheavals. Historians who admire Napoleon consider these innovations as the "granite masses" on which modern French society developed.

Campaigns and conquests: 1797 to 1807. Napoleon's sway over France depended from the start on his success in war. After his conquest of northern Italy in 1797 and the dissolution of the first coalition, General Bonaparte intended to invade Britain, France's century-long rival and the last remaining belligerent. Concluding that French naval power could not sustain a seaborne invasion, however, he launched a military expedition to Egypt instead, hoping to choke off the main route to Britain's Indian empire. When the expedition bogged down in disease and military stalemate, its commander quietly slipped past a British naval blockade to return to France, where (in the absence of accurate news from Egypt) he was received as the nation's leading military hero.

At the time of the Brumaire coup the republic's armies had been driven from Italy by a second coalition, but they had halted a multifront assault on France by the armies of Russia, Austria, and Britain. The republic, in other words, was no longer in imminent military danger, but the prospect of an interminable war loomed on the horizon. After Brumaire the nation expected its new leader to achieve peace through decisive military victory. This promise Bonaparte fulfilled, once again leading

French armies into northern Italy and defeating Austria at the Battle of Marengo in June 1800. Subsequent defeats in Germany drove Austria to sign the peace treaty of Lunéville in February 1801. Deprived of its continental allies for the second time, a war-weary Britain finally decided to negotiate. In March 1802 France and Britain signed the Treaty of Amiens, and for the first time in 10 years Europe was at peace.

Treaty of Amiens

Within two years, however, the two rivals were again in a state of war. Most historians agree that neither imperial power was solely responsible for the breakdown of this peace since neither would renounce its ambitions for supremacy. Napoleon repeatedly violated the treaty's spirit—by annexing Piedmont, occupying the Batavian Republic, and assuming the presidency of the Cisalpine Republic. To Britain, the balance of power in Europe required an independent Italy and Dutch Netherlands. Britain violated the letter of the treaty, however, by failing to evacuate the island of Malta as it had promised.

Once again, British naval power frustrated Napoleon's attempt to take the war directly to British soil. At the Battle of Trafalgar (Oct. 21, 1805), British naval gunners decimated the French and Spanish fleets. Against Britain's newly enlisted continental allies Napoleon had better luck, as he confronted them one by one before they could effectively unite. Moving his army rapidly across Europe, Napoleon surprised the Austrians at Ulm and then smashed them decisively at the Battle of Austerlitz (Dec. 2, 1805), probably his most brilliant tactical feat. Under the Treaty of Pressburg (criticized by the French foreign minister Talleyrand as entirely too harsh), Austria paid a heavy indemnity, ceded its provinces of Venetia and Tyrol, and allowed Napoleon to abolish the Holy Roman Empire. Prussia, kept neutral for a time by vague promises of sovereignty over Hanover, finally mobilized against France, only to suffer humiliating defeats at the battles of Jena and Auerstadt in October 1806. The French occupied Berlin, levied a huge indemnity on Prussia, seized various provinces, and turned northern Germany into a French sphere of influence. The ensuing campaign against Russia's army in Europe resulted in a bloody stalemate at the Battle of Eylau (Feb. 8, 1807), leaving Napoleon in precarious straits with extremely vulnerable lines of supply. But, when fighting resumed that spring, the French prevailed at the Battle of Friedland (June 14, 1807), and Tsar Alexander I sued for peace. The Treaty of Tilsit, negotiated by the two emperors, divided Europe into two zones of influence, with Napoleon pledging to aid the Russians against their Ottoman rivals, and Alexander promising to cooperate against Britain.

Napoleon's satellite kingdoms

The Grand Empire. Napoleon now had a free hand to reorganize Europe and numerous relatives to install on the thrones of his satellite kingdoms. The result was known as the Grand Empire. Having annexed Tuscany, Piedmont, Genoa, and the Rhineland directly into France, Napoleon placed the Kingdom of Holland (which until 1806 was the Batavian Commonwealth) under his brother Louis, the Kingdom of Westphalia under his brother Jérôme, the Kingdom of Italy under his stepson Eugène as his viceroy, the Kingdom of Spain under his brother Joseph, and the Grand Duchy of Warsaw (carved out of Prussian Poland) under the nominal sovereignty of his ally the king of Saxony. To link his allied states in northern and southern Germany, Napoleon created the Confederation of the Rhine. Even Austria seemed to fall into Napoleon's sphere of influence with his marriage to Archduchess Maria Louise in 1810. (Since the emperor had no natural heirs from his marriage to Joséphine Beauharnais, he reluctantly divorced Joséphine and in 1810 married the Austrian princess, who duly bore him a son the following year.)

The continental system. Britain, however, was insulated from French military power; only an indirect strategy of economic warfare remained possible. Thus far Britain had driven most French merchant shipping from the high seas, and in desperation French merchants sold most of their ships to neutrals, allowing the United States to surpass France in the size of its merchant fleet. But after his string of military victories Napoleon believed that he could choke off British commerce by closing the Continent to its ships and products. With limited opportunities to sell its manufactured goods, he believed, the British economy would suffer from overproduction and unemployment, while the lack of foreign gold in payment for British exports would bankrupt the treasury. As France moved into Britain's foreign markets, Britain's economic crisis would drive its government to seek peace. Accordingly, Napoleon launched the "continental system": in the Berlin Decree of November 1806, he prohibited British trade with all countries under French influence, including British products carried by neutral shipping. When the British retaliated by requiring all neutral ships to stop at British ports for inspection and licenses, Napoleon threatened to seize any ship stopping at English ports. Thus a total naval war against neutrals erupted.

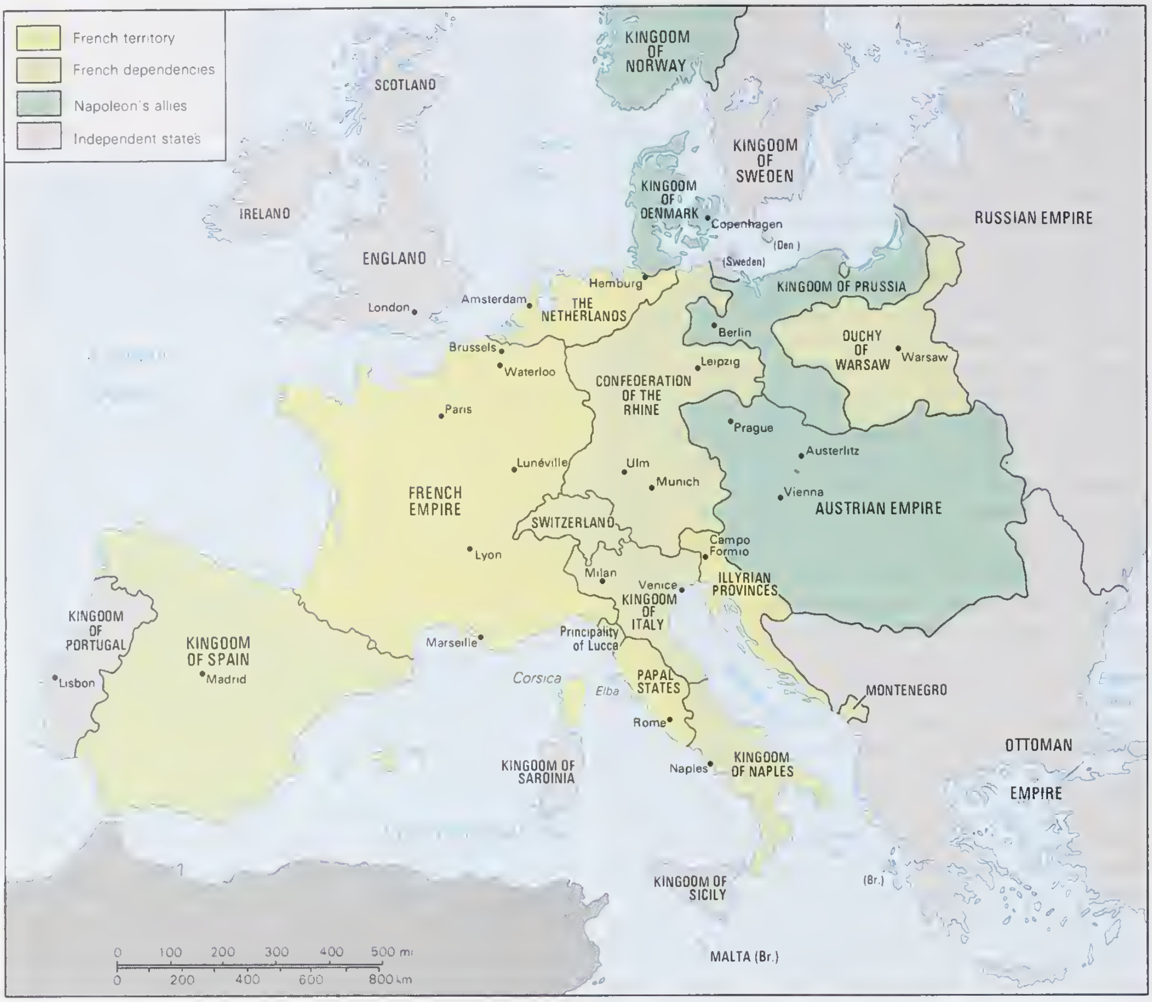
Economic warfare took its toll on all sides. While France did make inroads in cotton manufacturing in the absence of British competition, France and especially its allies suffered terribly from the British blockade, in particular from a dearth of colonial raw materials. The great Atlantic ports of Nantes, Bordeaux, and Amsterdam never recovered, as ancillary industries like shipbuilding and sugar refining collapsed. The axis of European trade shifted decisively inland. The continental system did strain the British economy, driving down exports and gold reserves in 1810, but the blockade was extremely porous. Since Europeans liked British goods, smugglers had incentive to evade the restrictions in places like Spain and Portugal. By 1811, moreover, a restive Tsar Alexander withdrew from the continental system. Thus, the most dire effect of the continental system was the stimulus it gave Napoleon for a new round of aggressions against Portugal, Spain, and Russia.

The invasion of Russia

By 1810 almost 300,000 imperial troops were bogged down in Iberia, struggling against a surprisingly vigorous Spanish resistance and a British expeditionary force. Then, in 1812, Napoleon embarked on his most quixotic aggression—an invasion of Russia designed to humble "the colossus of Northern barbarism" and exclude Russia from any influence in Europe. The Grand Army of 600,000 men that crossed into Russia reached Moscow without inflicting a decisive defeat on the Russian armies. By the time Napoleon on October 19 belatedly ordered a retreat from Moscow, which had been burned to the ground and was unfit for winter quarters, he had lost two-thirds of his troops from disease, battle casualties, cold, and hunger. The punishing retreat through the Russian winter killed most of the others. Yet this unparalleled disaster did not humble or discourage the emperor. Napoleon believed that he could hold his empire together and defeat yet another anti-French coalition that was forming. He correctly assumed that he could still rely on his well-honed administrative bureaucracy to replace the decimated Grand Army.

Conscription. Building on the Directory's conscription law of September 1798, the Napoleonic regime, after considerable trial and error, had created the mechanisms for imposing on the citizens of France and the annexed territories the distasteful obligation of military service. Each year the Ministry of War Administration assigned a quota of conscripts for every department. Using communal birth registers, the mayor of each commune compiled a list of men reaching the age of 19 that year. After a preliminary examination to screen out the manifestly unfit and those below the minimum height of five feet one inch, the young men drew numbers in a lottery at the cantonal seat. Doctors in the departmental capitals later ruled on other claims for medical exemptions, and in all about a third of the youths avoided military service legally as physically unfit. For obvious reasons, married men were not exempt from the draft, but two other means of avoiding induction remained, apart from drawing a high number: the wealthy could purchase a replacement, and the poor could flee.

Initially the regime had a bad conscience about allowing replacements, since this made its rhetoric about the duties of citizenship sound hollow. But to placate prosperous peasants and notables, it did permit the hiring of a replacement under strict guidelines that made it difficult and costly but not impossible. Between 5 and 10 percent of all French draftees were replacements. For Napoleon's



Europe in 1812.

Draft evasion

prefects, the annual conscription levy was the top priority and draft evasion the number one problem in most departments. Persistence, routine stepped-up policing, and coercion gradually overcame the chronic resistance. Heavy fines levied against the parents of evaders did little good since most were too poor to pay them. But billeting troops in their homes was more effective, and, if they could not feed the troops, the community's wealthier taxpayers were required to do so. By 1811 the regime had broken the habit of draft evasion even as the demand for conscripts increased. In 1812, prefects all over France reported that the annual levies were less contentious than ever.

Napoleon had begun by drafting 60,000 Frenchmen annually, but by 1810 the quota hit 120,000, and the first of many "supplementary levies" was decreed to call up men from earlier classes who had drawn high numbers. In January 1813, after the Russian disaster, Napoleon replenished his armies by calling up the class of 1814 a year early and by repeated supplementary levies. Because he could still rely on his conscription machine, Napoleon consistently rebuffed offers by the allies to negotiate peace. Only after he lost the decisive Battle of Leipzig in October 1813 and was driven back across the Rhine did the machine break down. His call of November 1813 for 300,000 more men went largely unfilled. With the troops at his disposal the emperor fought the Battle of France skillfully, but he could not stop the allies. Shortly after Paris fell, he abdicated, on April 6, 1814, and departed for the island kingdom of Elba. France was reduced to its 1792 borders, and the Bourbons returned to the throne. Altogether—along with large levies of Italians, Germans, and other foreigners from the annexed territories and satellite states—nearly 2.5 million Frenchmen had been drafted by Napoleon, and at least 1 million of these conscripts never returned.

The most sympathetic explanation for Napoleon's relentless aggression holds that he was responding to the irreducible antagonism of Britain: French power and glory were the only antidotes to John Bull's arrogance. Others have argued that Napoleon's vendetta against Britain was merely a rationalization for a mad 10-year chase across Europe to establish a new version of Charlemagne's empire. This "imperial design" thesis, however, makes sense only in 1810, as a way Napoleon might have organized his conquests and not as the motivation for them. (Only retrospectively did Napoleon write: "There will be no repose for Europe until she is under only one Head . . . an Emperor who should distribute kingdoms among his lieutenants.") In the end one is thrown back on the explanation of temperament. In his combination of pragmatism and insatiable ambition, this world-historic figure remains an enigma. Increasingly "aristocratic" at home and "imperial" abroad, Napoleon was obviously something more than the "general of the Revolution." And yet, with Civil Code in one hand and sabre in the other, Napoleon could still be seen by Europeans as a personification on both counts of the French Revolution's explosive force.

NAPOLEON AND THE REVOLUTION

The Revolutionary legacy for Napoleon consisted above all in the abolition of the ancien régime's most archaic features—"feudalism," seigneurialism, legal privileges, and provincial liberties. No matter how aristocratic his style became, he had no use for the ineffective institutions and abuses of the ancien régime. Napoleon was "modern" in temperament as well as destructively aggressive. But in either guise he was an authoritarian with little patience for argument, who profited from the Revolution's clearing operations to construct and mobilize in his own fashion. His concept of reform exaggerated the Revolution's emphasis on uniformity and centralization. Napoleon also accepted the Revolutionary principles of civil equality and equality of opportunity, meaning the recognition of merit. Other rights and liberties did not seem essential. Unlike others before him who had tried and failed, Napoleon terminated the Revolution, but at the price of suppressing the electoral process and partisan politics altogether. Toward the end of the empire, his centralizing vision took over completely, reinforcing his personal will to power. France was merely a launching pad for Napoleon's boundless military and imperial ambition, its prime function being to raise men and money for war. In utter contrast to the Revolution, then, militarism became the defining quality of the Napoleonic regime.

The Battle of Waterloo

Napoleon's ambiguous legacy helps explain the dizzying events that shook France in 1815. When Louis XVI's brother returned as King Louis XVIII, he courted popularity by ending conscription and by agreeing to rule under a constitution (called the Charter), which provided for legislative control over budgets and taxes and guaranteed basic liberties. But the Bourbons alienated the officer corps by retiring many at half pay and frightened many citizens by not making clear how much of their property and power the church and émigrés would regain. As the anti-Napoleonic allies argued among themselves about the spoils of war, Napoleon slipped back to France for a last adventure, believing that he could reach Paris without firing a shot. At various points along the way, troops disobeyed royalist officers and rallied to the emperor, while Louis fled the country. Between March and June 1815—a period known as the Hundred Days—Napoleon again ruled France. Contrary to his expectation, however, the allies patched up their differences and were determined to rout "the usurper." At the Battle of Waterloo (June 18, 1815) British and Prussian forces defeated Napoleon's army decisively, and he abdicated again a few days later. Placed on the remote island of Saint Helena in the South Atlantic, he died in 1821. The "Napoleonic legend"—the retrospective version of events created by Napoleon during his exile—burnished his image in France for decades to come. But in the final analysis Napoleon's impact on future generations was not nearly as powerful as the legacy of the French Revolution itself. (I.Wo.)

France since 1815

THE RESTORATION AND CONSTITUTIONAL MONARCHY

Constitutionalism and reaction, 1815–30. *Louis XVIII, 1815–24.* King Louis XVIII's second return from exile was far from glorious. Neither the victorious powers nor Louis's French subjects viewed his restoration with much enthusiasm, yet there seemed to be no ready alternative to Bourbon rule. The allies avenged themselves for the Hundred Days by writing a new and more severe Treaty of Paris. France lost several frontier territories, notably the Saar basin and Savoy (Savoie), that had been annexed in 1789–92; a war indemnity of 700 million francs was imposed; and, pending full payment, eastern France was to be occupied by allied troops at French expense.

The reactionaries

Within France, political tensions were exacerbated by Napoleon's mad gamble and by the mistakes committed during the First Restoration. The problem facing the Bourbons would have been difficult enough without these tensions—namely, how to arrive at a stable compromise between those Frenchmen who saw the Revolutionary changes as irreversible and those who were determined to resurrect the ancien régime. The reactionary element, labeled ultraroyalists (or simply "ultras"), was now more intransigent than ever and set out to purge the country of all those who had betrayed the dynasty. A brief period of "white terror" in the south claimed some 300 victims; in Paris, many high officials who had rallied to Napoleon were dismissed, and a few eminent figures, notably Marshal Michel Ney, were tried and shot. The king refused, however, to scrap the Charter of 1814, in spite of ultra pressure. When a new Chamber of Deputies was elected in August 1815, the ultras scored a sweeping victory; the surprised king, who had feared a surge of antimonarchical sentiment, greeted the legislature as *la chambre introuvable* ("the incomparable chamber"). But the political honeymoon was short-lived. Louis was shrewd enough, or cautious enough, to realize that ultra policies would divide the country and might in the end destroy the dynasty. He chose as ministers, therefore, such moderate royalists as Armand-Emmanuel du Plessis, Duke de Richelieu, and Élie Decazes—men who knew the nation would not tolerate an attempt to resurrect the 18th century.

There followed a year of sharp friction between these moderate ministers and the ultra-dominated Chamber—friction and unrest that made Europe increasingly nervous about the viability of the restored monarchy. Representatives of the occupying powers began to express their concern to the king. At last, in September 1816, his ministers persuaded him to dissolve the Chamber and order new elections, and the moderate royalists emerged with a clear majority. In spite of ultra fury, several years of relative stability ensued. Richelieu and Decazes, with solid support in the Chamber, could proceed with their attempt to pursue a moderate course. By 1818 they were able, thanks to loans from English and Dutch bankers, to pay off the war indemnity and thus to end the allied occupation; at the Congress of Aix-la-Chapelle France was welcomed back into the concert of Europe. In domestic politics there were some signs that France might be moving toward a British-style parliamentary monarchy, even though the Charter had carefully avoided making the king's ministers responsible to the Chamber of Deputies. In the Chamber something anticipating a party system also began to emerge: ultras on the right, independents (or liberals) on the left, constitutionalists (or moderates) in the centre. None of these factions yet possessed the real attributes of a party—disciplined organization and doctrinal coherence. The most heterogeneous of all was the independent group—an uneasy coalition of republicans, Bonapartists, and constitutional monarchists brought together by their common hostility to the Bourbons and their common determination to preserve or restore many of the Revolutionary reforms.

The advance of the left

The era of moderate rule (1816–20) was marked by a slow but steady advance of the liberal left. Each year one-fifth of the Chamber faced reelection, and each year more independents won seats, despite the narrowly restricted suffrage. The ultras, in real or simulated panic, predicted disaster for the regime and the nation; but the king clung stubbornly to his favourite, Decazes, who by now was head of the government in all but name, and Decazes, in turn, clung to his middle way.

The uneasy balance was wrecked in February 1820 by the assassination of the king's nephew, Charles-Ferdinand, Duke de Berry. The assassin, a fanatical Bonapartist, proudly announced his purpose: to extinguish the royal line by destroying the last Bourbon still young enough to produce a male heir. In this aim he failed, for Caroline, Duchess de Berry, seven months later bore a son, whom the royalists hailed as "the miracle child." But the assassin did bring to an end the period of moderate rule and returned the ultras to power. In the wave of emotion that followed, the king dismissed Decazes and manipulated the elections in favour of the ultras, who regained control of the Chamber and dominated the new Cabinet headed by one of their leaders, Joseph, Count de Villèle.

This swing toward reaction goaded some segments of the liberal left into conspiratorial activity. A newly formed secret society called the Charbonnerie, which borrowed its name and ritual from the Italian Carbonari, laid plans for an armed insurrection, but their rising in 1822 was easily crushed. One group of conspirators—"the four sergeants of La Rochelle"—became heroic martyrs in the popular mythology of the French left. Subversion gave the government an excuse for intensified repression: the press was placed under more rigid censorship and the school system subjected to the clergy.

Meanwhile, the ultras were winning public support through a more assertive foreign policy. Spain had been in a state of quasi-civil war since 1820, when a revolt by the so-called liberal faction in the army had forced King Ferdinand VII to grant a constitution and to authorize the election of a parliament. The European powers, disturbed at the state of semianarchy in Spain, accepted a French offer to restore Ferdinand's authority by forcible intervention. In 1823 French troops crossed the Pyrenees and, despite predictions of disaster from the liberal left, easily took Madrid and reestablished the king's untrammeled power. This successful adventure strengthened the ultra politicians and discredited their critics. In the elections of 1824 the ultras increased their grip on the Chamber and won a further victory in September 1824 when the aged Louis XVIII died, leaving the throne to a new king who was the very embodiment of the ultra spirit.

Ascendancy of the ultras

Charles X, 1824–30. Charles X, the younger brother of Louis XVIII, had spent the Revolutionary years in exile and had returned embittered rather than chastened by the experience. What France needed, in his view, was a return to the unsullied principle of divine right, buttressed by the restored authority of the established church. The new king and his Cabinet—still headed by Villèle—promptly pushed through the Chamber a series of laws of sharply partisan character. The most bitterly debated of these laws was the one that indemnified the émigrés for the loss of their property during the Revolution. The cost of the operation—almost one billion francs—was borne by government bondholders, whose bonds were arbitrarily converted to a lower interest rate. A severe press law hamstrung the publishers of newspapers and pamphlets; another established the death penalty for sacrilegious acts committed in churches.

Along with these signs of reaction went a vigorous campaign to reassert the authority of the Roman Catholic church, which had been undermined by Enlightenment skepticism and by the Revolutionary upheaval. Under the Bourbons several new missionary orders and lay organizations were founded in an effort to revive the faith and to engage in good works. Catholic seminaries began to draw increasing numbers of students away from the state lycées. Charles X threw himself enthusiastically into the campaign for Catholic revival. The anticlericals of the liberal left were outraged, and even many moderates of Gallican sympathies were perturbed. Rumours spread that the king had secretly become a Jesuit and was planning to turn the country over to "the men in black."

King Charles and his ultra ministers might nevertheless have remained in solid control if they had been shrewd and sensitive men, aware of the rise of public discontent and flexible enough to appease it. Instead, they forged stubbornly ahead on the road to disaster. Villèle, though a talented administrator, lacked creative imagination and charismatic appeal. As the years passed, his leadership was increasingly challenged even within his own ultra majority. A bitter personal feud between Villèle and François-Auguste-René, Viscount de Chateaubriand, the most colourful of the ultra politicians, undermined both the ministry and the dynasty. This internal conflict contributed to Villèle's downfall; the elections of 1827 brought a sharp resurgence of liberal and moderate strength. The king patched together a disparate ministry of moderates and ultras headed by an obscure official, Jean-Baptiste, Viscount de Martignac. But Martignac lacked Charles's confidence and failed to win the support of the more moderate leftists in the Chamber. In 1829 the king brusquely dismissed him and restored the ultras to power.

The delayed consequences of this act were to be fatal to the dynasty. The king, instead of entrusting power to an able ultra such as Villèle or a popular one such as Chateaubriand, chose a personal favourite, Jules-Auguste-Armand-Marie, Prince de Polignac, a fanatical reactionary. The makeup of the Cabinet, which included several members of the most bigoted faction of "ultra-ultras," seemed to indicate the king's determination to polarize politics. That, in any case, was the immediate result. On the left the mood turned aggressively hostile; the republicans of Paris began to organize; an Orleanist faction emerged, looking to a constitutional monarchy headed by the king's cousin, Louis-Philippe, Duke d'Orléans. The liberal banker Jacques Laffitte supplied funds for a new opposition daily, *Le National,* edited by a young and vigorous team whose most notable member was Adolphe Thiers. A confrontation of some sort seemed inevitable.

The polarization of politics

Some of Polignac's ministers urged a royal coup d'état at once, before the rejuvenated opposition could grow too strong. Instead, the king procrastinated for several months, offering no clear lead or firm policy. When the Chamber met at last in March 1830, its majority promptly voted an address to the throne denouncing the ministry. The king retaliated by dissolving the Chamber and ordering new elections in July. Both Charles and Polignac hoped that pressure on the electors, plus foreign policy successes, might shape the outcome. Such a success was won at just the opportune moment: news came that Algiers had fallen to a French expeditionary force sent to punish the Bey for assorted transgressions. But even this brilliant victory could not divert the fury of the king's critics. The opposition won 274 seats, the ministry 143. Charles's alternatives were now clear: to substitute a moderate for Polignac and accept the role of constitutional monarch or to risk a royal coup d'état that would leave the Charter of 1814 in tatters. Without hesitation he chose the second path. King and ministers prepared a set of decrees that dissolved the newly elected Chamber, further restricted the already narrow suffrage, and stripped away the remaining liberty of the press. These July Ordinances, made public on the 26th, completed the polarization process and ensured that the confrontation would be violent.

The Revolution of 1830. The July Revolution was a monument to the ineptitude of Charles X and his advisers. At the outset, few of the king's critics imagined it possible to overthrow the regime; they hoped merely to get rid of Polignac. As for the king, he naively ignored the possibility of serious trouble. No steps were taken to reinforce the army garrison in Paris; no contingency plans were prepared. Instead, Charles went off to the country to hunt, leaving the capital weakly defended. During the three days known to Frenchmen as Les Trois Glorieuses (July 27–29), protest was rapidly transmuted into insurrection; barricades went up in the streets, manned by workers, students, and petty bourgeois citizens (some of them former members of the National Guard, which Charles, in pique, had disbanded in 1827). On July 29 some army units began to fraternize with the insurgents. The king, on July 30, consented at last to dismiss Polignac and to annul the July Ordinances; but the gesture came too late. Paris was in the hands of the rebels, and plans for a new regime were crystallizing rapidly.

As the insurrection developed, two rival factions had emerged. The republicans—mainly workers and students—gained control of the streets and took over the Hôtel de Ville, where on July 29 they set up a municipal commission. They looked to the venerable Marquis de Lafayette as their symbolic leader. The constitutional monarchists had their headquarters at the newspaper *Le National;* their candidate for the throne was Louis-Philippe, Duke d'Orléans. Louis-Philippe was at first reluctant to take the risk, fearing failure and renewed exile; Adolphe Thiers undertook the task of persuading him and succeeded. On July 31 Louis-Philippe made his way through a largely hostile crowd to the Hôtel de Ville and confronted the republicans. His cause was won by Lafayette, who found a constitutional monarchy safer than the risks of Jacobin rule; Lafayette appeared on the balcony with Louis-Philippe and, wrapped in a tricolour flag, embraced the duke as the crowd cheered. Two days later Charles X abdicated at last, though on condition that the throne pass to his grandson, "the miracle child." But the parliament, meeting on August 7, declared the throne vacant and on August 9 proclaimed Louis-Philippe "king of the French by the grace of God and the will of the nation."

The abdication of Charles X
